London is principally supplied with salmon from Scotland. When fresh, they are sent packed up with ice in boxes; and those that are pickled in small kists, such as were first used in Newcastle for that purpose. Although the sums drawn in this country from the metropolis come to a very considerable annual amount, yet were proper regulations for this fishery established by law, and duly enforced, not only a great increase in the trade would take place, but Scotland would be more abundantly provided in salmon for home consumption.

For an account of the Whale Fishery, see Whale Fishery; an account of the Pearl Fishery, will be found in our article Ceylon, Vol. V. p. 700; and of the Anchovy Fishery under our article Anchovy. See also Ireland. (a. d.)

FISHES, ELECTRICAL. See Electricity Index. FISHING. See Angling. FISTULA. See Surgery. FIUME, or St Veit, is a sea port town of Istria. It is situated on the Bay of Fiume, in the Gulf of Venice, at the mouth of the Fiumara or Reka, at the commencement of a narrow valley, abounding in wines and excellent fruits. The town is agreeably built, and contains several good public buildings. The churches are
particular magnificence. The cathedral, which was not finished when Kiesler visited this city, was adorned with several beautiful marble pillars and statues. The Jesuit’s church is of a circular form, and has a small cupola. Fiumara has long been celebrated for its wax manufacture, and the refinery for sugar supplies the whole of the Austrian states with that article. Many individuals find employment from these two establishments. The harbour, which is formed by the river Fiumara, is well frequented. There are here several considerable commercial houses, and great quantities of goods which come from Hungary are exported from this place. The town is populous. East Long. 14° 42’, North Lat. 45° 45’. See Kiesler's Travels, vol. ix. p. 129, 5vo; and L. F. Cassa’s Travels in Istria and Dalmatia. (4)

FIXED SOUND of M. Sauveur. About the beginning of the 18th century, the author above named took a great deal of pains, in endeavouring to introduce a greater degree of precision into the notation and practice of music, and with the view of determining the pitch, he proposed, that A in the lowest space of the bass-stave, should be denominated the fixed sound, and make just 100 complete vibrations in one second of time. Now the tenor cliff C being a minor tenth (4⁴) above this A, we have 1200 + 52 = 240 for the vibrations of this C, which being also the result of several modern experiments on this subject, (see our article Concert Pitch,) we have always used this pitch in calculating vibrations and beats in our work.

M. Sauveur also proposed another fixed sound or pitch, which has since been adopted by Dr Thomas Young, and some other writers, in which an imaginary C, eight octaves below the tenor cliff C, should make exactly one vibration per second; and consequently the latter would make 256 vibrations, which is to 240 as 16:15, shewing that the former pitch is just a major semitone higher than the latter one in present use; and that for the mere purpose of simplicity of description, an erroneous idea of the actual pitch has thus been conveyed to the student, but which future writers may avoid, by representing the fixed sound I per sound, as belonging to Db, eight octaves below that, which is the next above the tenor-cliff C. (5)

FLAME. See CHEMISTRY.

FLAMSTEAD, John, a celebrated astronomer, was born, according to some, in the village of Denby, in the county of Derby, on the 19th of August 1646, although others maintain that he was born in the town of Derby. The registers of both of these parishes were examined in order to ascertain this point, but his birth does not seem to have been registered, probably on account of the commotions which at that time agitated England. His father resided at Derby, and he received his classical education at the free school of that place. At the age of 14, a severe illness obliged his friends to take him home, where the accidental perusal of Sacrobosco’s treatise De Sphaera inspired him with a passion for astronomy. By means of the Caroline tables, published by Street, he was instructed in the method of computing eclipses, and the places of the planets. One of his calculations of an eclipse, procured him the friendship of Mr Emanuel Halton, residing at Wingfield manor, who was well acquainted with the mathematics, and who supplied young Flamstead with the best astronomical works then extant, among which were Riccioli’s Almagestum Novum, and Kepler’s Rudolphine Tables. With these aids he made rapid advances in the knowledge of astronomy, and in the year 1669 he sent a paper to Lord Bruncker, President of the Royal Society, entitled, “An Account of such of the more remarkable Celestial Phenomena of the year 1670, as will be conspicuous in the English Horizon.”

This paper was read and approved of, and obtained for young Flamstead the friendship and correspondence of some of the first astronomers in London. In the year 1670, Flamstead undertook a journey to London, for the purpose of seeing his scientific friends; and he had the good fortune to become acquainted with Sir Jonas More, Mr Collins, and Mr Oldenburg, the first of whom was ever afterwards his patron and warmest friend. When in London, he purchased two telescopes, a micrometer, and several other instruments with which he had not been provided. After leaving London, he entered himself a student of Jesus College, Cambridge, where he became acquainted with Dr Barrow and Sir Isaac Newton. As soon as he returned to Derby, he resumed his astronomical studies. In 1671, he sent to the Royal Society calculations of the appulses of the moon to several fixed stars, for the year 1672; and about the end of the same year, he transmitted another communication, containing his observations on the phase of the planet Saturn, made with telescopes, the largest of which was fourteen feet long. In the same year, he observed, with a Townley's micrometer adapted to the preceding telescope, the relative position of the principal stars in the Pleiades, and he computed their occlusion by the moon in the subsequent year. In 1673, he composed a treatise on the true and apparent diameters of the planets, which Sir Isaac Newton employed in the 4th book of the Principia. When he was in London in 1674, Sir Jonas More having informed him, that a true account of the tides would be acceptable to the king; he composed a small ephemeris for his majesty’s use. He likewise recommended himself to the royal favour, by presenting to his Majesty a pair of barometers, with the method of using them. Having resolved to enter the church, Mr Flamstead was ordained by Bishop Gunning in 1675, but several years elapsed before he obtained any preferment. Through the influence chiefly of Sir Jonas More, King Charles II. was prevailed upon, in 1676, to found the royal observatory of Greenwich, afterwards called Flamstead-house, and to appoint Flamstead to the office of Astronomer Royal, with a salary of £100 per annum. On August 21, 1676, he observed at Greenwich, the occultation of Mars. In the beginning of 1677, he observed the comet of that year. In the year 1681, Flamstead's Treatise on the Doctrine of the Sphere was published in Sir Jonas More's System of the Mathematicks; and in 1687, he was presented to the living of Bramley in Surry, which he retained till his death.

As soon as he had entered upon his new office, Flamstead directed almost the whole of his attention to practical astronomy. By means of the best instruments of the times, he observed the lunar motions with great assiduity, and he determined the places of the fixed stars with much greater accuracy than had been done before. Contrary to the wishes of Flamstead, an edition of his observations was published in 1712, by Dr Halley, in one volume folio; but as he would never acknowledge this work as his own, he prepared a new edition of it, but before its completion he died of strangury on the 31st of December 1719, in the 73rd year of his age.

Mr Flamstead was admitted a member of the Royal
Society on the 15th of February 1678, and he contributed to the transactions of that learned body a great variety of valuable papers. His celebrity, however, is chiefly founded on his *Historia Celestis Britannica*, a work in three volumes folio, which was published by his widow in 1725. See *Astronomy*, vol. ii. p. 599.

Flamstead is represented by his biographers as of a morose and unsociable disposition, and as having been on bad terms with most of his contemporaries. "From some of his letters," says Dr. Thomson, *(History of the Royal Society, p. 335)* "it even appears that he complained of Sir Isaac Newton as unreasonable in his demands of observations. Dr. Halley, in the preface of the *Historia Celestis Britannica*, draws rather an unfavourable picture of the disposition of Flamstead; and I find, from one of Sir Hans Sloane's MSS. in the British Museum, that, in the year 1710, he was expelled the Royal Society, because he refused to pay his annual contribution." (o)

FLANDERS, the name of a maritime province in the Netherlands. It was formerly divided into Austrian, French, and Dutch Flanders. It now belongs to Holland and France, which see.

FLAT, in Music, a, or flattened intervals, are such as are depressed or lessened a degree of the scale, a chromatic semitone, or FINGER-KEY INTERVAL (see that article.) As it happens, with the Numerals, 1, 2, 3, 3, 3, &c. of the diatonic scale, that the major and minor of the same Numeral (see that article,) are not at the same invariable distance from each other; so the flats of the literals, d, e, f, &c. are not at one invariable distance from their naturals D, E, F, &c. although in tempered scales this is obliged to be the case. Mr. Liston has correctly explained these matters, in his "Essay on perfect Intonation;" but it may be proper here to put the student on his guard, against the mistakes and incongruities of other authors, by enumerating their different flats.

FLAT, of Dr. Boyce, in some parts of his MS. in the library of the Royal Institution, is =S, or 57 4+4+5 m.

FLAT, double, of Liston, is invariably $+1/2$, or $832 + 2f$. $+1/2$. 7. $+1/2$. 4. $+1/2$. 5.

FLAT, double, (bb), of Chambers and Overend; sometimes 2 P, or 116 $+2+4+10$ m.; at others, P $+$ S, or 105 $+4+2+9$ m.

FLAT, of Liston, to the notes D, G, B, or C, is $=S$, or 47 $+4+4+4$ m.; and to the notes E, F, or A, is $=d$, or 36 $+4+3$ m., the second flat of any note being always the reverse of its first one.

FLAT, of Marsh, $=d$, or 36 $+4+3$ m.

FLAT, of Maxwell, $=S$, or 47 $+4+4+3$ m.

FLAT, of Overend, (and Dr. Callcott, Mus. Gram. 1st ed. p. 112.), $=P$, or 58 $+4+5$ m.; this corresponds with perfect fifths. See the theories below.

FLAT, of some writers, $=L$, or 46 $+4+4+4$. $+4+4+4$. 5.

FLAT, of regularly tempered Scales, is the minor limina of Dr. R. Smith, which, according to Mr. Farley's theorems, Phil. Mag. vol. xxxix. p. 44, is $=582 +4+5$ m.—seven times the temperament of the Vth: Or, $=85.75196562 +4+3$ m. seven-fourths of the temperament of the llrd: Or, $=23.9966500 +4+2$ m. seven-thirds of the temperament of the Vth.

From hence we see, by way of examples, that in the mean-tone system, where the temperament of the llrd = 1, the flat is $=58.75196562 +4+5$ m., being $=1+1+1+1+1+1$ etc.; or for the flat of the legion scale, we may either use the temperament of the Vth, 1.00065322, of the llrd, 7.00034102, or of the Vth, 8.00038632, and either of the above theorems will give $51.0003276 +4+4+4$ m., being $=1+1+1+1+1+1+1+1$ etc.; and, in the system where the major sixths are perfect, the flat is $=P-2+4+4$. (q)

FLECHIER, Esprit, bishop of Nismes, an eminent French ecclesiastic, was born at Peres, a small town near Carpentras, on the 10th of June 1632, of obscure but respectable parents. He was educated at Tarascon, in a college possessed by the congregation formerly known in France under the name of the *Doctrinaires*, fathers of the Christian doctrine, of which his maternal uncle was, at that time, general. At the age of fifteen, having finished his studies, he employed himself, for some years, in teaching the *belles lettres*, in the same college. Some time after he repaired to Paris, and having determined to fix his residence in that city, he accepted employment in a parish, and afterwards undertook the education of the son of M. Lefebvre de Caumont. From this period, his reputation rapidly increased, in consequence of the discourses which he delivered on different festivals of the church; and his celebrity procured him admission into the Academy, in the year 1673. He had the honour of preaching before Louis XIV. on Advent, 1682.

For his preferment, and the many favours he received from the king, Flechier was principally indebted to the active patronage and friendship of the Duke of Montausier, who had already procured for him two benefices, and the abbacy of St. Severin, besides the office of almoner to the dauphin; when, in the year 1682, he was selected as one of a mission, which was destined to bring back into the bosom of the church, the Protestants of Poitou and Brittany, of which mission Fenelon was the chief. On his return, he was appointed to the bishopric of Lavaur, which he held for two years, and was then translated to the more lucrative see of Nismes. The duties of this charge, however, were much more troublesome than those of the former, on account of the great number of Calvinists who were then in open revolt, or ready to break out, against whom the church was called on to act, with an equal and disastrous effect, revolving that of Nantes, was rigorously executed. In this difficult situation, the high character of Flechier became eminently conspicuous.

By his mildness, moderation, and persuasive address, he contributed to assure the sanguinary zeal of the Catholics; his humane virtues conciliated the good will of all parties, and he received unequivocal testimonies of regard even from the Calvinists, amidst the horror and devastation of civil war.

When these troubles were at length appeased, he was enabled to devote himself, without obstruction, to the exercise of a zealous and active benevolence. There was not a single charitable institution at Nismes, which was not either founded by him, or indebted to his liberality for support. His favours were indiscriminately conferred upon unfortunate persons of all descriptions, without regard to religious opinions; and in the disastrous winter of 1709, his charity was only limited by the total expenditure of his funds. When some one, upon that occasion, represented to him the disagreeable consequences which might ensue to himself from such profuse liberality, he answered, "What you say is, perhaps, very true; but are we bishops for nothing?" He was as much the enemy of superstition and fanaticism, as he was zealous for the maintenance of pure religion; and he laboured with ardour and efficacy to re-construct his clergy and to re-establish the Catholic Church, and to enlighten the people from that blind ignorance and credulity, which are often abused for the purpose of mislead-
In 1797, the number of sailors was 1597. There are no fewer than 200 establishments for manufacturing and distilling brandy, and these have served, at the same time, to fatten 4000 head of cattle, and as many swine.

The town also contains five refineries of sugar, 40 manufactories of tobacco, and several tanneries. The position of the town, according to trigonometrical observations, is; East Long. 0° 27' 40", and North Lat. 54° 47' 18". See Kuttner's Travels through Denmark, Sweden, &c. Lett. 1.; and Catteau Calleville, Tableau de la Mer Baltique; tom. ii. p. 325. (w)

FLETCHER, Andrew, of Salton, in East Lothian, was a statesman and a patriot of the highest order; and though Scotland, his native land, was the chief object of his exertions, yet, wherever the love of country and of liberty prevails, he deserves to be remembered with respect and gratitude. His powers, too, were called forth at a period of the greatest importance in the British annals. His paternal grandfather, whose Christian name he bore, was one of the fifteen Judges of the Court of Session, by the style of Lord Innerpeffer. His father was Sir Robert Fletcher of Salton and Innerpeffer; and his mother, whose name was Catharine, daughter of Sir Robert Bruce of Clackmannan, derived her descent from the royal and truly illustrious race of Bruce. Andrew Fletcher was the eldest son of this marriage, and was born in the year 1659, though in some sketches of his life the date of his birth is stated to be 1650. The celebrated and excellent Gilbert Burnet was but 10 years older than young Fletcher; and, as Sir Robert Fletcher presented him to the rectorship of Salton, which he filled with most exemplary fidelity from 1664 to 1669, Andrew enjoyed the rare advantage of having his principles formed, and his mind cultivated, by Dr. Burnet, to whom his father, at his death, wisely consigned the care of his son.

Gifted by nature with uncommon powers, it is not surprising that, under such a preceptor, he made rapid progress in classical knowledge, historical erudition, and general literature. His hereditary love of liberty, connected with his indignation at the tyrannical proceedings which marked the conduct of the administration of Charles the Second after the restoration of that unprincipled king, gave an unfavourable bias to his temper, and seems even to have made him regret that union of the crowns of Scotland and England which was so essentially conducive to the peace and prosperity of both divisions of the island.

Having simply qualified himself, by the deep and solid foundation which had been laid by Burnet and his other instructors, for receiving improvement, by personal observation of men and manners, he travelled for some time on the Continent, and was, soon after his return, elected to represent East Lothian in the Scottish parliament, which consisted only of a single house. While James, Duke of York, acted as lord high commissioner in Scotland, Fletcher distinguished himself in particular by his strenuous opposition to the measures of the court, and particularly to the Bill of Accession. Having connected himself with the Earl of Argyile, he became so obnoxious that he found it necessary to consult his personal safety by leaving Scotland. After remaining for a time in retirement in London, where he had an opportunity of seeing and consulting his friend and former instructor Burnet, now a distinguished preacher, and occasionally a faithful monitor of King Charles, of whose personal and political profligacy he afterwards became the stanch opponent, Fletcher by his advice went to Holland, and was soon after declared an outlaw in Scotland, and his estate confis-
In the United Provinces he and many of the friends of religion and liberty found asylum.

He returned to England in 1683, with his friend and countryman Robert Baillie of Jerviswood, who, in the following year, died on a scaffold at Edinburgh, having aided or contrived at the expedition under the Duke of Monmouth, and the unfortunate Earl of Argyll. It is recorded to the honour of this virtuous man, that though he was offered his life on condition of revealing what he knew of Fletcher's connection with this fatal enterprise, he nobly rejected the proposal, and died, as he had lived, the friend of religious and civil liberty.

As to Fletcher, it appears that he acted a still more important part on that occasion than his friend; not only being a statesman, but having great knowledge in military affairs, he actually bore arms in that part of the expedition which landed in England, and served under Monmouth; but finding that, contrary to his engagement, that rash leader caused himself to be proclaimed king without the choice and consent of the people, and without any of those wise limitations which Fletcher considered necessary, he quitted his standard, and concealed himself till he found an opportunity of returning to the Continent. It is stated, that while he had the command of a party in this expedition, he killed the mayor of Lynn, in a dispute which arose about a horse belonging to that gentleman, which had been pressed into the service by his troops. It has even been said, that this event rendered him so unpopular in the little army, that it was deemed advisable for him to retire. Fletcher himself, however, complained of the gross injustice which had been done him in the account of that transaction; and, in his own account of his conduct on this occasion, which he afterwards gave to the Earl Mareschal of Scotland, he utterly denied that it had any thing to do with his leaving Monmouth; in proof of which he stated, that he had continued with him till the proclamation above alluded to was made at Taunton, which Fletcher regarding as a violation of the Duke's engagement, and of his duty to the nation, absolved him from all farther engagement to serve under him.

The vessel in which Fletcher made his escape, was bound for Spain. Information having, by some unknown means, reached the English minister at Madrid, of his arrival, he applied to the Spanish government, who caused him to be apprehended and put in prison, in order to his being transmitted to London. But he escaped in a manner so extraordinary, that if it had not formed a part of his account of himself to the Earl Mareschal, it might have been deemed incredible. On the eve of his departure, a stranger of a venerable aspect made signals to him through the bars of his prison. Fletcher, on looking around him, found a door unlocked; and, on going out at it, was joined by his deliverer, who conducted him in silence through three guards of soldiers, who were, or appeared to be, asleep. He was then assisted in escaping from the place, by another person equally unknown. He proceeded through Spain in disguise; and, having credit on a house in Amsterdam, he spent a considerable time in examining the scenery and curiosities of the country, and purchased many curious books, which the Earl of Buchan, in his Essay on the Life of Fletcher, informs us are still preserved in the family library at Salton. During his journey he met with several singular and providential deliverances, which he used to recount to his friends with pleasing and pious emotion, regarding them as proofs of the special protection of heaven.

We next find him serving as a volunteer in the Hungarian war under the Duke of Lorraine. Meanwhile he had not been an inattentive observer of the signs of the times in his native land; but, having availed himself of such opportunities as occurred, of learning what was going on at home and in Holland, he gave up his prospects of military fame and promotion, and joined the band of exiles and patriots from Britain, who were preparing at the Hague for the execution of the grand enterprise on which the liberties of his country were suspended. Having declined to accept James the Seventh's act of indemnity, under which several persons of distinction had recovered their estates and honours, he came over with the Prince of Orange in 1683, along with Bishop Burnet, Sir Patrick Humo, &c. The success of this grand effort is detailed in its proper place. At present, we have to do with Fletcher, who, whilst in Holland, asserted the rights and liberties of Scotland previous to the Revolution, against William Prince of Orange; with a firmness and unbending zeal which made him appear as desirous of giving the crown without the sceptre, and prevented him from being a favourite of the prince.

In the Convention Parliament which met in Scotland after the Revolution, he was a strenuous advocate for popular freedom and regal limitations; and it is a circumstance highly honourable to him, that, except regaining possession of his family-estate, which happened as a matter of course, he never seems to have enjoyed or desired any office, emolument, or pension, whatever. "Non sibi sed patriae" was the noble principle on which he acted. King William respected and feared him; but finding him "too fond of the right, to pursue the expedient," did not confide in him.

In Fletcher's Political Works, which were published in one 8vo. volume in 1737, we find seventeen speeches that had been delivered by him in the Scottish parliament, most of them about the year 1703; and all except three on the great questions which then agitated the nation, relative to the settlement of the Scottish crown, in the event of the death of Queen Anne without issue. In these speeches, which are certainly a great historical and literary curiosity, he advocates with great boldness the cause of popular right against royal privilege; laments the degeneracy of the nobility and people from the high spirit of their ancestors, and reproaches them for their servility to England. He brought in and supported a bill entitled "Act for the security of the Kingdom," which, had it passed, would have lodged the whole executive power in the hands of the parliament, and rendered the king a mere puppet to be shewn at a procession. Against this alarming project, the Queen's commissioner exerted all his influence, and even signified that as, without the touch of the royal sceptre officially given to the act, as the Scottish mode of expressing the royal assent, it would not have the force of a law; so that assent must be withheld, even if the scheme should obtain the sanction of parliament. Finding this could not be carried into a law, he formally moved, that "the proposed limitations should be declared by a resolution of the House of Parliament, to be the conditions upon which the nation will receive a successor to the crown of this realm, after the decease of her present Majesty, and failing heirs of her body, in case the said successor shall be also king or queen of England." (Fletcher's Political Works, 3 A)
FLETCHER.

Speeches No. III. and IV.) Even in the present age of free discussion, we can hardly find an instance of greater boldness than this. From the close of this motion, his dislike to the union of the crowns will be seen, as it evidently implies that if Scotland should choose a separate king, he would not consider so many limitations necessary. Yet even if this latter event had taken place, there is no doubt that Fletcher would have displayed his characteristic jealousy of princes in a manner calculated sufficiently to fetter the power of the crown. He did not hesitate afterwards boldly to assert the constitutional right of the Scottish parliament to separate the crown of Scotland from that of England, at the close of the then existing entail of the crown, and to express his conviction of the necessity of this measure for the welfare of his native land. Happily for Great Britain and the world these projects proved unsuccessful; and we cannot sufficiently wonder, that one so well acquainted with the nature of man, and with the constitutional and political history of the two divisions of the island, should have calmly formed such a design. It seems to us a striking proof of the power of early prejudice over the wisest and best-intentioned minds. Had William and Mary, or their successor Queen Anne, been as bigotted and tyrannical, as they were in truth liberal and tolerant in their domestic and foreign policy, we could with less difficulty have explained the conduct of Fletcher on this occasion.

We regret that none of his speeches on the union of the parliament of Scotland with that of England, which was proposed in the succeeding sessions, and which, after a great deal of angry and dangerous contention, was enacted in 1706, and actually carried into effect in 1707, have been published. His general sentiments on that subject will be found, however, in the amusing paper usually printed as the last in the volume of his works. It is entitled, "An account of a conversation concerning a right regulation of governments for the common good of mankind, &c. 1703." In the report of the characters and dialogue, he shews considerable dramatic skill; and in his own part of the scene, he displays a degree of politeness and address superior to any thing of this kind to be found in his parliamentary speeches. Though Fletcher did not succeed to the extent that he desired, he laid his country under great obligations, by the modified "Act of Security," which was eventually passed, and by the many wise and salutary provisions which he caused to be connected with the measure. One hundred and eighty years have now elapsed since this most important act of union was adopted; and the progressive improvement and happiness of the two countries fully warrant us to consider it as one of the greatest political blessings we enjoy. The gloomy predictions of its enemies have been completely reversed, and greater benefits have resulted from it than the most sanguine could have reasonably anticipated. Several of the principal speeches delivered by the opponents of this union have come down to us, and deserve to be preserved as curious memorials of opinions that have passed away. Of these, perhaps the most eloquent is that of Hamilton, Lord Belhaven, in which, with much poetical pathos, he drew a most affecting picture of its evil consequences. With peculiar and almost prophetic felicity, the Earl of Marchmont replied: "I have heard a long speech, and a very terrible one; but it requires only this short answer, Behold! he dreamed; lo, when he awoke, he found it was a dream."

The Earl of Buchan, who published his brief memoir of Fletcher chiefly on the authority of a manuscript history of the family, gives no account of him beyond the year 1703; and does not even notice the time or manner of his death. We think it extremely probable that he had a seat in the parliament of Great Britain; but that the advanced period of his life, and his dissatisfaction with the union, prevented him from taking a leading part in the deliberations of that body. He died in London in the year 1716, at the age of 63. His remains were brought to Scotland, and interred in the family vault at Saltoun.

As a man, Andrew Fletcher was endowed with high talents, great courage, integrity, generosity, and temperance. On the purity of his intentions as a patriot, the exertions and sufferings of his life form the best commentary. He was a most elegant scholar, and an accomplished orator. His speeches are remarkable for their plainness and energy, and form, by their brevity, a striking contrast to the wordy eloquence of the present day. His "Discourse concerning the affairs of Spain," originally published in the Italian language, but which appeared in an English dress in the 12mo edition printed at Glasgow in 1749, displays an ample and profound acquaintance with the interest, policy, and connections of the continental states, as well as of Great Britain, and shews him to have been deeply acquainted with the doctrine of the balance of power, which has since been the theme of so much discussion, and the cause of so much strife among the philosophers, politicians, and warriors of Europe. His "Discourse on the establishment of a national militia," is learned and ingenious, but too Utopian to admit of a practical application. His "Two Discourses on the affairs of Scotland," contain many curious views of the state of society at the time when they were written. On one topic only, we must offer a few remarks. These Discourses were written in 1693, when, in consequence of some years of barrenness, a scarcity, or rather a famine, existed through the land, and occasioned the most severe sufferings to the lower classes. The author declares, that besides those who were scantily provided for out of the church boxes, there were at the time when he wrote, not less than 200,000 persons in Scotland begging from door to door. "And though," he observes, "the number of them be perhaps double to what it was formerly, by reason of this present distress, yet in all time there have been about 100,000 of those vagabonds, who have lived without any regard either to the laws of the land, or even to those of God and nature." He tells us also, that when he considers the many excellent laws enacted by former parliaments, for setting the poor to work, particularly those made in the reign of James VI. contrasted with their utter insutility; when he considered farther, that all the other nations in Europe, Holland excepted, groaned under a similar pressure, he was led to suspect that neither the cause nor the remedy of the evil had been discovered. As no such evil had been complained of by the classical writers of antiquity, and as much poverty was the consequence, in Europe, of the manumission of slaves by their Christian masters, he gravely supposes that the existence of domestic slavery was the cause of the comfort and industry of the lower orders in former times. It will hardly be credited by those who are acquainted with his high notions of political right, and his constant jealousy of the power and ambition of princes, that he proposes reducing all those persons and their posterity to slavery, by a solemn act.
of the legislature, that on the one hand they might be compelled to work, and on the other might be insured of the necessaries of life. A more extraordinary remedy for a public evil, all circumstances considered, was never surely devised; and though he guards the projected plan against the danger of leading to extreme oppression, by statutes and humane regulations, we may safely say, that a less justifiable or less effectual remedy could hardly have occurred to a thinking mind. The evil has long since disappeared, in consequence, chiefly, perhaps, of the provision for public instruction in the principles of religion and morality, made by an act of the Scottish parliament, two years before Fletcher's discourse was written, viz. in 1696. We regret that the accounts of this excellent man are so meagre and scanty; and we consider a good account of his life and writings as an important desideratum in the literature of our native country. (!)

FLINTSHIRE, is a maritime county, and the most northern in North Wales. It consists of a narrow slip of land, that runs from north-west to south-east; and is bounded by the Irish Sea on the north; by the estuary of the Dee, and the county of Chester, on the north-east and east; and by Denbighshire on the south and west. At the distance of some miles from the main body of the county there is a detached portion, separated by the interposition of Denbighshire, and nearly surrounded by Shropshire and Cheshire. This detached piece consists of the hundred of Maenor Saesneg. Maenor, in the Welsh language, signifies a place of traffic, mart, or market. There were formerly many districts so demoted, near the marches or boundaries of the principalities, which were considered neutral ground, where trade was carried on. This detached portion of Flintshire, therefore, was most probably the neutral ground, on which the English, or Saesneg, as the Welsh even yet stile them, met the latter for the purposes of traffic.

Flintshire, with the exception of the isle of Anglesey, is the smallest of the Welsh counties, the main portion of it being about 28 miles in length, and in no place above 10 in breadth,—generally much less. Its circumference is 115 miles. Its area contains 309 square miles, or 197,760 statute acres. It is divided into five hundreds, viz. Coleshill, which contains 4 parishes, 3 townships, and 1 borough; Maenor, the disjoined hundred already mentioned, which contains 5 parishes, 1 extra parochial place, 9 townships, and 1 chapelry; Mold, which contains 2 parishes, 2 townships, and 1 chapelry: Prestatyn, which contains 4 parishes, and 3 townships; and Rhuddlan, which contains 8 parishes, 1 township, and the town of Holywell. The number of entire parishes in the county is 16, and there are 8 parts of parishes. It contains one city, St Asaph; one county town, Mold; five market towns. It is in the province of Canterbury, and the diocese of St Asaph and Chester. It is in the same circuit with the latter county; the assizes are held at Mold. It returns two members to parliament, one for the county, and one for Flint; or rather, the right of election is vested in the inhabitants of the boroughs of Flint, Rhuddlan, Overton Caerwyys, and Caergurley, including the inhabitants of Knolleton and Overton foreign, paying scot and lot, who amount to about 1000 voters. Flintshire pays one half part of the land-tax.

This county is not nearly so uneven in its surface as any other parts of Wales. The northern extremity, as well as the detached part, is mostly a level tract; and the southern portion is agreeably diversified with hill and dale. On the Denbighshire side, the county is backed by a lofty chain of mountains, that overlook the Vale of Clywd; from the banks of the Dee, the land rises rapidly to a ridge of hills, which run for a considerable way parallel to that river. The Vale of Mold, in the southern part of the county, is uncommonly rich and beautiful. The Vale of Clywd, also, partly belongs to Flintshire; the city of St Asaph being situated on the river Clywd, in the centre of it. At this place, the vale is between four and five miles broad.

The low part of Flintshire consists, for the most part, of a clayey or loamy soil: whereas, the soil of the hills is lighter, and much more barren. The rivers which are the Dee, Clywd, Wheeler, Sevion, and Allen; but only the last three can properly be described under the head of this county. The Wheeler rises near Caerwyys, a market-town near the middle of the county; its course is nearly west, and it falls into the Clywd almost opposite Denbigh. The Sevion rises to the north of Caerwyys; its course is also west, and it falls into the Clywd a few miles to the north-west of St Asaph. The Allen rises a few miles to the south of Ruthin, in Denbighshire; at first, its course is to the north; it next winds to the east; and falls into the Dee to the north of Wrexham in Denbighshire. Near the town of Mold, this river sinks under ground, and is lost for a short space. The climate of Flintshire partakes, though not in a very great degree, of the nature of the climate of North Wales; being rather mild near the sea, but wet: the hilly parts are exposed to cold and sharp winds.

Flintshire presents nothing striking or instructive in an agricultural point of view. On the flat tracts, in its northern extremity, a considerable quantity of corn is grown, especially wheat, of which a good deal is exported to Liverpool. In the rest of the low portion of the county, the land is applied to the production of both corn and grass. Flintshire is one of the breeding counties of Wales. The cattle are of the common small black kind, for the most part: formerly the farmers kept a great number of bees, from the honey of which they made mead or mead; but this practice is now greatly discontinued. The low part of the county is well-stocked with wood.

The importance of Flintshire is derived almost entirely from its mineral productions; of these, the lead mines in the vicinity of Holywell are the most valuable and curious. The entrance to one of the largest is through a water level, cut from the bottom of the lowest shaft: at the extremity of the level is a mill, which is turned by the waste water from the mine. The first 600 yards of the canal are cut through slate and cherts: the remainder, (700 yards), through hard limestone. The veins of this mine are unusually rich, the principal seam being from five to six feet thick. Sixteen miners are usually employed in it. The great bank of ore is usually found about 40 yards from the surface, dipping down gradually almost as low as the level. The ore is chiefly galena; considerable quantities of calamine are also procured. Some kinds of the lead ore contain silver sufficient to repay, with profit, the expense of separating it from the lead; and several thousand ounces of silver have been annually extracted in this county, and sent to the manufactures of Sheffield and Birmingham. The calamine is partly exported, and partly used in the brass works near Holywell. In the south-eastern parts of the county, there are considerable coal mines, from which the city of Chester is in a great measure supplied. Millstones are also found in Flintshire; and some years ago as they were sinking coal pits in the parish of Mold, a sort of black slate was
Flintshire.

found, with a very distinct impression of the leaves of plants on it. At Caergwrley, in this county, is a mineral water, which contains a small proportion of sea salt, a little calcareous earth, and a portion of muriate of magnesia. The famous well of St Winifrid at Holywell, which was formerly so much visited and used for its supposed miraculous healing powers, is, in fact, only a most copious stream of very cold and very pure water. It is contained within a handsome shrine adjoining the church, and issues forth from a large well at the foot of a high hill; over the well an elegant Gothic roof is raised: it afterwards flows into a stone reservoir, forming the consecrated bath, and after a farther course of about a mile, unites with the Dee.

The principal manufactures in Flintshire are those of copper and brass near Holywell. The refined copper is received from Swansea and Hanley in the form of solid blocks or grises. The articles of chief importance exported from these works, are copper sheets and nails for sheathing ships. Copper bolts for ships, copper and brass wire, copper plates for various purposes, many of them most beautifully polished in a lathe, manillas, bracelets, &c. copper and brass pans, some of them of vast size used at home, others very broad and shallow, sent to Africa, where they are used in making salt from the sea water by evaporation in the sun. The whole of the manufactured copper and brass is shipped out the Dee, just below the manufactory, and sent to Liverpool, whence it is exported to India, America, and all the mechanical power, which is very great, is given by the stream from the Holywell to large water wheels of cast iron. Besides affording the requisite power for these works, the Holywell turns water mills for corn, snuff, cotton, &c. so that, in the short course of one mile, it turns 11 great wheels. The cotton spun here is much esteemed, on account of the uniform texture and quality produced by the constant and regular force which this body of water exerts, discharging about 21 tons in a minute from the spring, and never freezing, even in the severest winters. Near Northop are considerable potteries, at which are made large quantities of coarse earthen ware, much of which is exported to Ireland.

From the returns to the House of Commons in 1803, respecting the state of the poor, it appears that the money raised for their support in Flintshire that year amounted to £16,130 7s. 8d., whereas in 1783, 1784, and 1785, it averaged only £805 9s. 5d., and in 1776 it was only £4176 10s. 8d.; the average rate in 1803 was 5s. 4½d. in the pound. No money appears to have been earned by the poor towards their own support. The number of persons relieved out of workhouses was 1372, in workhouses 25. There were 18 friendly societies, containing 2307 members. The number of children in the schools of industry was 62.

From the returns under the property act, it appears, that in 1810, the annual value of property in this county, from land, houses, tithe, quarries, mines, &c. amounted to £146,732; and it is remarkable that there is no tithe free land in it. The amount of the incomes from trades was £43,371.

Population.

In 1700, the population of Flintshire was 19,500: in 1750, 29,700; in 1801, 41,000; and in 1811 there were,

| Inhabited houses | 8,816 |
| Families in them | 9,740 |
| Houses building | 51 |
| uninhabited | 155 |

From Caergwrley, this county extends into Caernarvon, through the Vale of Clwyd, and is bounded on the north by the Dee, and on the south by the Dwy for the most part.

The baptisms brought to account in the parish registers, are four to each marriage: to every 31 of the population, there appeared to be one baptism, and one burial to every 53, and one marriage to every 15 of the population.

At the invasion of the Romans, Flintshire was inhabited by the Ordovices; it was called by the former Venedesi, probably from the Veneti, in Armorica, who, according to Caesar, frequently visited Britain. The Ordovices were the last of the British tribes conquered by the Romans. On a marsh in the neighbourhood of Rhuddlan, was fought, in 795, a battle between the Saxons and Welsh, in which the latter were defeated; their prince, Caradog, was slain, and the event was deemed so disastrous, that a plaintive tune, still popular in Wales, was composed on the occasion.

The antiquities in this county are few, and not of Antiquities. much moment. Bod-farrri on the Clywdd, to the south-east of St Asaph, is supposed to be the Varis of Antoninus: near this city, also, are the remains of a circular fortification; and near Hope, in the south-east of the county, a Roman hypocaust or hot-bath, was discovered some years ago. On Mostyn mountain, there is a stone pillar, with characters on it, hitherto not deciphered.

Flint Town is a small town on the Dee, governed by a mayor and 2 bailiffs: it is without trade. It was formerly noted for its castle, built on a rock close to the sea. In it Richard II. took shelter on his arrival from Ireland; but having quitted it, he was taken prisoner by the Duke of Lancaster. The castle is now in ruins. The town contains 1423 inhabitants.

FLORENCE, a celebrated city of Italy, is situated on the banks of the river Arno, in North Lat. 43° 46' 30", and East Long. 6° 15' 45", according to sidereal observations. It is distant 150 miles from Rome, and about 60 from the shores of that part of the Mediterranean called the Mare Infernum, or Tuscan Sea.

few cities have received from nature more advantages than Florence. The Valdarno, or Vale of the Arno, is the Arcadia of the Italian poets; and even Milton himself frequently alludes to the exquisite beauties of its scenery.

O ego quantum eram, gelidum cum stratus ad Arni Murmurum populeum quae nixum, quae molliis herbis Carpere nunc vident, nunc summis carpere myriis.

Epit. Dan.

Behind the city rise hills covered with olive and fig trees, and other plants, natives of the warmer climates; still farther are high mountains, clothed with immense forests of chestnut trees, and adorned with small towns,
Florence.

sometimes boldly rising on their sides, and at other times half concealed in their woods and recesses; while beyond them, in the distance, rise the naked and rugged summits of the lofty Apennines. The whole valley is one continued grove and garden, where the beauty of the country is enlivened by the animation of the town, and the fertility of the soil, redoubled by the industry of its cultivators. Such indeed is the richness of the plain, that five crops of wheat or maize are taken in the course of three years. The trees in the hedge-rows are covered with vines, which are trained upon their stems; while the white villas that gleam through the orchards, and the populous hamlets that line the roads and the banks of the river, present on every side a scene of comfort and prosperity.

The city itself spreads along the side of the river, which forms one of its greatest ornaments. Its streets are well paved, or rather flagged, wider than usual in southern climates; and its houses in general solid, and rather stately. It has several squares, and many churches and palaces, so that its appearance is airy, clean, and sometimes rising towards grandeur.

The first edifice which arrests the attention of the traveller is the cathedral, (commonly called in Florence Il Duomo,) a building of great extent and magnificence, and in boldness and skill inferior only to St Peter's at Rome. This building is 426 feet in length, and 363 in height. It is completely cased with polished black and white marble, and the interior paved with variegated marble, part of which was arranged by Michael Angelo.

Its most remarkable feature, however, is the dome, which was raised under the directions of Philip Brunellesco, the most celebrated architect of the 15th century. The dimensions are within a few feet of the dome of St Peter's; and as it is prior to it in date by nearly a century, and was always the peculiar object of Michael Angelo's admiration, we may conclude, that the plan of the Roman edifice was at least in part suggested by the Florentine. But, in many respects, the inferiority of the latter is undeniable. The octagonal shape so simple, has consequently less grandeur than the circular, and, from being closed at the top, there is a want of light to illuminate the vast vault below. This is indeed the general defect of the church, the windows being small, and the little light they admit diminished by the deep and rich colours of the painted glass. Such at least is the opinion of Italian critics, though to British eyes, accustomed to associate ideas of sublimity with the gloomy grandeur of our Gothic cathedrals, these very defects will appear to be excellencies. The statues which adorn the church both within and without, are most of them the works of the most eminent sculptors, and a few of the pictures are of the first rate of excellence. Among the most remarkable of the former, are the statue of Brunellesco, and those on the altar, the productions of Bandinelli and Michael Angelo. Of the latter, those in the interior of the dome by Zuccheri and Vasari, and the portraits of Dante and Giotto, are most worthy of attention; the first, for their intrinsic beauty, and the others, on account of the distinguished character of the men by whom they are executed. Detached from the church stands the belfry, a light and elegant tower, incrusted with variegated marble, and, like the church, adorned with statues. The general baptistery of the city, which fronts the principal entrance of the church, is also an octagonal building of great magnificence. It is chiefly remarkable for the baso relieves which adorn its three great bronze portals. They are the work of Andrea Ugalini, of Pisa and Lorenzo Ghiberti, and were so highly admired by Michael Angelo, who called them the "Gates of Paradise." Before the principal gate of the baptistery are two columns of porphyry, on which are suspended the immense chains with which the Pisans, in 1406, attempted to close up their harbour against the Florentines and Genoese, and which were afterwards brought to Florence as a trophy of victory. See Civil Architecture, vol. vi. p. 518, and Plate CLXXXIII where we have given a plan and vertical section of this church.

The next, and indeed the only other church which deserves a particular description, is that of San Lorenzo in the northern part of the city. This also was planned by Brunellesco, but is, both in design and magnificence, inferior to the former. It has, however, attained to high celebrity, from two buildings attached to it, the Sacristy and the Medicien Chapel. The first was one of the earliest works of Michael Angelo, and is decorated with 7 statues by the same artist; and although most of them are unfinished, yet the eye of the connoisseur will easily discern in them, the genius and boldness of design, which so eminently characterize the productions of that great sculptor.

The chapel which adjoins the back of the church was begun in 1604 by Ferdinand I. Grand Duke of Tuscany, who intended not only to have removed thither the mausoleum of his ancestors, but was in treaty to purchase the holy sepulchre at Jerusalem. The plan of the building was every way worthy of the purpose for which it was intended. "Its form is octagonal, its diameter 94, and its elevation to the vault 200 feet. It is literally lined with lapis lazuli, Jasper, onyx, &c. furnished with sarcophagi of porphyry, and supported by granite pilasters with capitals of bronze. The niches between these pilasters are of touchstone; beneath is a subterraneous chapel, where the bodies, whose names are engraved on the sarcophagi above, are to repose. The crucifixion of our Saviour, a group in white marble by John of Bologna, with a blessed Virgin by Michael Angelo, and St John by one of his pupils, "grace this dormitory of the dead, and preside over it with appropriate majesty. But,

Novia mens hominum futi: sortique future,

before the magnificent monument intended for their reception was finished, the Medicien line has failed; the work is now suspended; and, if we may judge from the impoverished state of the country, and the agitation of the times, it is not likely to be resumed for many years, if ever." The Laurentian library, which is in the convent annexed to the church, is a collection of valuable manuscripts, first formed by Cosmo and Lorenzo di Medici, and considerably increased by Leo X. and Clement VII. Of these, however, several of the most valuable have been removed to Paris.

In the other churches of Florence, though not deficient in internal decoration, there is but little to interest the traveller, except the recollections which the tombs of the illustrious men, whose ashes they contain, are calculated to excite. It is indeed impossible to pass by unnoticed the edifices where repose the remains of a Guicciardini or Machiavelli; of a Michael Angelo or Galileo.

The palaces of Florence are remarkable for a style of architecture peculiar to themselves, to which the long years in the 15th century between the Guelfph and Ghibelline families first gave rise. The Palazzo Strozzi and the Palazzo Ricardi, the latter of which was built by the great Cosmo de Medici, are curious specimens of this style. They are square, heavy, solid masses, whose
strength is their principal ornament. The walls are thick, and broken by few windows, and these of a very diminutive size, and the whole basement fortified with large unhewn masses of stone. The upper stories are faced with freestone, and the whole is crowned with a very heavy projecting cornice.

In those palaces, which are the property of private persons, there are many pictures and statues by the best masters. Of these, the collections in the Riccardi and Gerini palaces are the most valuable. The Palazzo Vecchio and Pitti, the residences of the grand dukes, and more lately of the king of Etruria, were completely stripped of their pictures and statues by the French, and the only monuments of art that now adorn them are modern ceilings, which it was impossible for the capacity of the invaders to remove. But of all the collections of the works of art, no one has acquired so high a reputation as the Medicean gallery. This magnificent building was erected by Cosmo I. in the year 1564; but the greatest part of its contents were collected in the succeeding century by the Cardinal Leopold de Medici, son of Cosmo II. and many additions were made by the princes of Lorraine and Austria. The busts of the Medicean princes and other contributors to the gallery adorn the vestibule, and, like the tutelary deities of the place, seem to claim from the passing traveller the homage due to their munificence. The gallery, or corridor, is in the shape of a Greek Π, of which the two wings are each 350 feet in length, and the intermediate part 97. The paintings and statues in the gallery are arranged in series of Florentine portraits,—of illustrious foreigners,—of painters, &c. and, the busts of all the Roman emperors and their families, from Julius Cæsar to Constantine. The corridor is bordered on one side by a suite of halls or cabinets, each of which is considered to contain some sets of masterpieces either in sculpture or painting, or collections of antique and modern medals, coins, gems, &c. Of the former, many of the most celebrated now grace the galleries of the Louvre, and the hall of the far-famed Venus de Medicis is now a temple bereft of its divinity. Of those that remain, the most remarkable is the group of Niobe and her children; it consists of 16 figures, which are generally considered as models of the highest perfection; although it is a subject of debate among critics, whether this group be a copy, or the original, which is ascribed by Pliny the elder to the chisel of Scopas or Praxiteles.

A minute description, however, of this celebrated collection would exceed our limits; and we must refer our readers for this and the account of the natural history museum, to the Museum Florentinum, the Panorama of Florence, and similar publications.

In 1782, Florence was calculated to contain about 107,000 inhabitants; if, however, in this, as well as other respects, it has followed the fate of the other Italian cities; the long period of misery and war which has since ensued, must have greatly diminished its population.

As early as the 14th century, while the Venetians and Genoese were contending for superiority in the Levant, Florence had become powerful, and its citizens wealthy, by their attention to commerce. As they were not at that time, however, possessed of a seaport, their care and attention was principally directed to the improvement of their manufactures, and objects of domestic industry. It appears from a contemporary historian, that the silks and cloths of Florence were the chief manufactures in the 14th century. From their connections they acquired in various parts of Europe, and their individual wealth, the Florentines were naturally led to banking, and became in this, as in their zeal for liberty, the successors of the citizens of the free states of Lombardy. And such was the superiority they acquired, that the money trade of almost all the kingdoms of Europe fell into their hands; and in several states, the collection and administration of the public revenues were even confided to their care. The immense fortunes which were acquired in these ways, enabled the Florentines to enter into a still wider range of commercial exertion: and soon after the conquest of Pisa, we find Cosmo de Medici endeavouring to obtain for his countrymen a share in the Indian trade, then carried on by the Genoese and Venetians. In this he succeeded, by concluding a treaty with the Sultan of Egypt, by which they were admitted to an equal share of all the privileges and immunities enjoyed by the Venetians in Alexandria. But the commercial greatness of Florence fled with her liberty, and with her fersook the fertile plains and groves of the Arno, for the less highly favoured valleys of Britain, and the frozen shores of the Baltic.

The present trade of Florence consists entirely in the sale of the productions of her own territory, and her manufactures, &c. Of the former, the chief are her raw silks, oil, and wines. Of the latter, the most celebrated is the manufacture of silks, which still continue to be esteemed. These are principally taffetas, damasks, and velvets. There are also manufactured stuffs, mixed with gold, and silks, satins, and light stuffs, commonly called Florence taffetas. There are a variety of other manufactures, among which their fine porcelain has attained to high celebrity. The Tuscan porcelain has been introduced with great success into Britain by the late Mr. Wedgwood.

It is difficult to ascertain with certainty the precise era of the foundation of Florence. It appears to have been a place used for markets and fairs by the Etruscan inhabitants of the town of Fiesole, (now Fiesole,) whose situation, on one of the rocky eminences that command the Valdarno, was ill adapted for such purposes; and the first houses in Florence were the booths erected for the accommodation of traders. Under the government of Sylla, it became the seat of a Roman colony. The walls of the new city were first traced out by that dictator, and it is supposed to have acquired its name from the officer who had the charge of the settlement of the infant colony.

We find but little mention of it in history during the period that elapsed from the time of Sylla, till the latter ages of the Roman empire. But there can be no doubt, that, from the beauty of its situation, and its convenience for inland commerce, it must have greatly increased in population and riches. At the time that it was almost entirely destroyed by Totila, king of the Goths, during his war with the generals of the Emperor Justinian, Florence abounded in baths, theatres and aqueducts, a sure indication of the wealth and luxury of its inhabitants.

During the iron sway of the Lombards in Italy it continued in ruin and obscurity until the end of the eighth century, when it was rebuilt by Charlemagne, after that monarch had completely annihilated the Lombard government.

Under the feeble princes of the Carolingian family, during the anarchy of the reigns of the dukes of Friuli, and the other petty sovereigns, who successively assumed the title of king of Italy, and the subsequent disputes
between the German emperors and the bishops of Rome, Florence, like the other cities of Tuscany and Lombardy, was gradually acquiring strength along with the spirit of liberty and independence.

Exposed to sudden assaults of hordes of Saracens, Bulgarians, and other barbarious nations, against whom their powerless lords were unable to assist them, the first step towards freedom was the right granted them of surrounding their city with walls and fortifications. It was not, however, until the reign of Otto I. about the middle of the tenth century, that the people were allowed to elect magistrates for themselves, and establish a regular municipal government. The constitution adopted by the Florentines, was a deliberative council, or senate of 100 persons; and, for the execution of justice, consuls who were chosen from among the most respectable class of citizens. Of these there were originally four, elected by the four quarters of the city. When it was increased to six divisions, two new consuls were also added, who were elected in the same manner.

In the year 1207, the consuls were deprived of the right of judging in civil cases, and of pronouncing and executing criminal sentences, and these duties were assigned to a magistrate styled a Podesta. It was enacted, that this person should be a foreigner, that no citizen might draw upon himself odium, by the execution of public justice; while, on the other hand, he might not be deterred by motives of fear, or family partialities, from doing what was necessary for the public safety.

Although the Florentine government appears to have occasionally taken part in the quarrels between the emperors and the popes, and especially in that of Otto IV. and Innocent III. yet the internal peace of the state remained undisturbed. It was not until the year 1215, that a private quarrel having on a sudden kindled the spirit of party, the Florentines were engaged in a civil war, which, after continuing for 33 years with various success, at length terminated in the banishment of the Guelph or Papal party, and forced the republic to take a decided part in the wars of Italy. Notwithstanding these long continued divisions, the republic seems not to have suffered either in point of population or wealth. The annals of that period talk of the necessary enlargement of the city, of the erection of public buildings, of the fortification of castles, with many other signs of its increase in strength and riches. It was, indeed, exclusively to such national purposes that the Florentines applied the fruits of their industry. Their manners and mode of living were simple to a degree, and all personal pomp and luxury were strictly repressed by sumptuary laws.

The power of the Ghibellines, or imperial faction, was but of short duration in Florence. The citizens, harassed by the tyranny of the nobles, suddenly took up arms in the year 1256, and having deposed the Podesta, conferred his authority on an officer styled the captain of the people, to whom they appointed as a council, 12 magistrates called Auziani, two of whom were chosen by each quarter of the city. To this council they gave the name of the Signory, and each of its members was to remain no longer in office than two months. The fortresses of the nobles were demolished, and the materials employed in repairing the walls of the city; and a public palace was built for the accommodation of the members of government. On the death of the Emperor Frederic II. in 1251, the people seized the opportunity of recalling the banished faction of the Guelphs, and having forced the chiefs of both parties to sign a treaty of peace; they added to the captain of the people a Podesta of a Guelph family in Milan. No sooner was the popular government established in Florence, than the citizens, animated by the strength they had acquired, endeavoured to bring over the whole of Tuscany to their party. For an account, however, of the wars that ensued, and the subsequent history of Florence, as connected with foreign transactions, we refer our readers to the article ITALY, confining ourselves at present to a brief sketch of the internal revolutions of the republic.

In the year 1258, the Ghibellines attempting to regain their ancient ascendancy, were, in their turn, expelled from Florence, and obliged to take refuge in Sienna. By that republic they were not only received but protected, notwithstanding the threats and declaration of war by the Florentine Signory. The Ghibellines soon acquired a still more powerful protector, Manfred, king of Sicily, who, at the solicitation of Farinata des Uberti, sent to their aid a small body of German cavalry. On the total defeat of these by the Florentines, Manfred, irritated at the disgrace, resolved to take a more active part in the war, and immediately sent 800 cavalry, besides infantry, into the state of Sienna, under the command of Girolamo d'Angione. Arming at this new addition of strength to their enemies, the heads of the Guelphs hesitated to attack them in the Sienese territory. But the people, partly influenced by their distrust of the nobles, and partly by the intrigues of two of the Anziani, whom Uberti had gained over by bribery, insisted on invading Sienna. The Florentine army accordingly took the field, consisting of 3000 cavalry and 30,000 infantry, and a battle was fought on the 4th September, 1260, at Monte Aperto, on the banks of the Arbia, where the Guelphs were completely defeated, with the loss of 10,000 killed, besides an immense number of prisoners. The consequence of this defeat was a second expulsion of the principal Guelphs, who, with their families, were, by the orders of the people, exiled from Florence, nine days after the battle.

At a diet of the Ghibelline states of Tuscany, it was seriously proposed to destroy completely the city of Florence, whose growing power and inclination to the opposite faction rendered it so dangerous to its neighbours; and this proposal meeting with approbation from the Tuscan deputies, was nearly agreed on, had not the firmness and eloquence of Farinata des Uberti, whose abilities so much contributed to the victory, been successful in altering the opinions of the diet, and preserving the independence of his country. For six years the Ghibellines retained the sovereignty, by the assistance of a garrison of the king of Sicily's soldiers commanded by Count Guido Novella. The spirit of the people, however, was hostile, and the tyrannical administration of Guido did not diminish their attachment to the pontifical faction.

The defeat of Manfred at Grandella by Charles of Anjou, and his subsequent death, raised the spirits of the exiles; and Count Guido, alarmed by an insurrection of the people, having deserted his post, the Guelphs, aided by 800 French under the command of Guy de Montfort, (son of the celebrated Earl of Leicester), re-entered Florence on Easter day 1267, and again expelled their ancient antagonists. Their whole property was immediately confiscated, and, after the loss sustained by the Guelphs was repaired, thrown into a fund, under the administration of particular magis-
the imperial faction, while, from the distinguished part Florence held among his opponents, it gave to that republic a much higher place in the scale of the Italian states than it had hitherto held. In fact, after this period, the history of Florence is so much involved in that of the revolutions of Italy, that it becomes impossible even to narrate the changes of its internal policy, without entering largely into the general history of the times; and we must therefore close this article by again referring our readers to the articles ITALY, TUSCANY, MEDICI, &c. (it.)

FLORIDA, a province in North America, is bounded on the north by Georgia; on the east, by the Atlantic; on the south, by the gulf of Mexico; and on the west, by the Mississippi. It extends between 500 and 600 miles, from east to west; and little more than 100 from north to south, except at its eastern peninsula, where the breadth is nearly 400 miles. It is situated between 25° and 31° of North Latitude, and between 80° and 92° of West Longitude. This country was first visited in 1497, by Sebastian Cabot, a Venetian mariner in the service of Henry VII. of England; but his History was more completely discovered by Juan Ponce de Leon, a native of Spain, in 1512. This navigator giving credit to an old tradition, that a fountain existed on the American continent, which had the property of bestowing perpetual youth, fitted out a small squadron, and bent his course towards the quarter where these precious waters were supposed to be concealed. Discovering land on Easter day, he gave it the name of Florida, from the Spanish name of that festival, Pasqua de Flores; or, according to Herrera, from the appearance of the country, which was covered with flowers, and the most beautiful blossoms. He landed on the coast; and, taking possession of the soil in name of his Catholic Majesty, he erected a stone with an inscription, commemorating his visit. But, having been prevented by the opposition of the natives from effecting a settlement, and, being disappointed in the chief object of his expedition, he returned to Puerto Rico. Another voyage was undertaken, in 1528, by Pampilho de Narvaez, who sailed with 400 men from the island of Cuba; and, attempting to penetrate into the interior of the country, was never more heard of. At length, in the year 1589, it was entirely subdued by Ferdinand de Soto, one of the bravest officers in the Spanish service; but it cost the Spaniards a long and bloody struggle before they were able to establish themselves in the country.

In 1564, the French began to form some small settlements on the coast; but they made little improvement of the natural advantages which the country presented, and devoted their whole attention to hunting and warlike excursions. The Spaniards, in the meantime, sent a fleet against their colony, and put all the settlers to the sword. A Frenchman, named De Gourges, made severe reprisals in 1597, demolishing the forts erected by the Spaniards, and murdering all the colonists whom he found in the country. From this period the French neglected America, and the Spaniards continued to make petty establishments on the coasts of Florida.

In 1586, their principal fort, St Augustine, was attacked by Sir Francis Drake, who reduced and pillaged the place; and, in 1665, it was entered and plundered by Captain Davis, at the head of a body of Buccaneers. In 1702, Colonel More, Governor of Carolina, attempting to annex the country to the British
dominions, marched a corps of 500 English and 700 Indians to the walls of St Augustine, and besieged it for the space of three months; but the Spaniards, having sent a squadron to the relief of the garrison, he raised the siege, and made a precipitate retreat, just when he was on the point of accomplishing his enterprise. When a British colony was settled in Georgia, in 1733, the Spaniards became very apprehensive of a new attempt upon Florida; and, in 1740, an expedition was fitted out against St Augustine by General Oglethorpe. But the Spanish commander having received intelligence of the intended attack, made such additional strength of the garrison, and adopted such skilful measures of defence, that the English were compelled, after sustaining considerable loss, to abandon their design. In 1763, Florida was ceded to Great Britain, in exchange for the Havannah, which had been taken from Spain; and, by the encouragement given to agriculture by its new masters, numbers of colonists poured into the country from the neighbouring provinces, the British isles, and all the Protestant nations of Europe. In the year 1781, it was again recovered by the Spaniards, and was guaranteed to them by the treaty of peace in 1783. In their possession it has remained from that period, and forms one of the three governments which compose the captainship-general of the island of Cuba. In 1810, a revolution took place in West Florida, disclaiming the authority of Spain; but the leaders were divided in opinion, whether they should maintain their independence as a separate state, or accede to the American confederation. They sent agents to Washington, who had an interview with the President of the United States; and, in the mean time, the American government have been prosecuting a claim upon the province since the year 1804, and in 1811 took measures for occupying the western division. This claim arose out of a dispute respecting the boundaries of Louisiana, which Spain had ceded to France in 1801, and which the latter power sold soon after to the United States, for the sum of fifteen millions of dollars. It is contended by the American government, that West Florida forms a part of Louisiana, which they purchased from France; and, on the ground of certain spoliations, alleged to have been committed by Spain on American commerce, they have advanced pretensions upon East Florida also, by way of indemnification. These pretensions have been supported by actual invasion; and there being little probability of a restoration or a re-conquest, the whole province may now be considered as included in the territory of the United States.

East Florida consists of a large peninsula, and a tract of land, extending from the mouth of the river St Mary westward, to the river Appalachicola. It lies between 30° 50' and 25° North Latitude, and between 80° and 85° West Longitude, extending from east to west from 100 to 190 miles, and from north to south from 100 to 400. West Florida lies between 67° and 75° West Longitude, and extends along the north coast of the Mexican Gulf, upwards of 500 miles from the river Appalachicola to the lakes Ponchartrain and Maurepas; thence along the river Liberisse to the Missisippi; and thence to the 31° North Latitude, from which a line drawn eastward to the river Appalachichola, forms its northern boundary. The sea coast of both provinces is low, and the country continues very flat for more than 40 miles inland, when it becomes a little hilly, interspersed with rocks. Towards the west, the rise is more gradual, and the surface more woody.

The coast is deeply indented with small gulfs and inlets, and intersected with numerous rivers. Along the south coast are several islands, which are included in the province, but which are of little importance or utility. The most remarkable are Cat Island, eight miles east of St Louis Bay, above six miles in length, and bordered with immense quantities of shells; Ship Island, about ten miles south of Biloxi Bay, nine miles long, and two broad; Port Island, about six miles farther east, very narrow, and about seventeen miles in length; Massacre Island, two miles east of the last mentioned, also very narrow, but nearly nine miles long; Dauphin Island, five miles farther east, six miles in length, and about two in breadth; Rose Island, a long and narrow sandy slip parallel to the coast, between Rose Bay and that of Pensacola; and the Tortugas, about ten in number, nearly opposite the most southern point of East Florida, covered with mangrove bushes, and extending ten or eleven miles from north-east to south-west. Some of these islands are mere sand, and none of them produce anything better than grass and pines. The principal island in the east coast is Anastasia, opposite to the town of St Augustine, divided from the mainland by a narrow channel, and twenty-five miles in length.

The rivers, which empty themselves into the Atlantic ocean, are St Mary's, the common boundary between Florida and Georgia, about a mile broad at its mouth; St John's river, rising in a marshy tract near the middle of the peninsula, and flowing gently northward, traverses several lakes, (the lowest of which, Lake George, is 20 miles long and 12 broad,) and falls into the sea about 40 miles south of the St Mary; and Indian river, which runs from north to south, and falls into the sea about 60 miles south of Cape Cavaeral. Most of the rivers which fall into the Gulf of Mexico, have their source in the province of Georgia, and the most worthy of notice are the Appalachicola, which divides East from West Florida, and is composed of two streams, the Flint and the Chattahoochee, rising in the Appalachian mountains, and uniting on the confines of Florida; the Escambia, the source of which is unknown to Europeans, and which empties itself into the bay of Pensacola; the Perdido, formerly the boundary between Louisiana and Florida, and falling into the sea four leagues west of Pensacola Bay; the Mobile, which has its source in the country of the Chickasaws, and, for 40 leagues of its course, is called the Tombocche, and which, after receiving the Alabama, becomes navigable nearly 120 miles from its mouth; the Pascagoula, which is navigable upwards of 150 miles, and which falls into the gulf about 16 miles west from Mobile Bay; the Pearl River, which originates in the Chaclaw territories, and is also navigable upwards of 150 miles; and the Atchafalaya, which is worthy of notice, chiefly as issuing from Lake Ponchartrain, which is 40 miles long and 24 broad.

St Augustine, the capital of East Florida, and originally founded by the Spaniards, about the year 1560, stands in 29° 45' North Lat. on the coast of the Atlantic Ocean. It is built at the neck of a peninsula, in an oblong form, and consists of four principal streets, which cut each other at right angles. It is fortified with bastions, and surrounded by a ditch, and is also defended by a castle called Fort St John, well provided with ordnance. The river St Mark flows through the harbour, and separates the town from the island Anastasia. The north and south breakers, at the entrance, form two channels, whose bars have eight feet of water: Pensacola...
FLORIDA.

cola, the capital of West Florida, was regularly laid out by the English in 1763; and is about a mile in length, of an oblong form, lying nearly parallel to the beach, and defended by a fort, which was built also by the English in 1775. In consequence of a low and sandy shore, only small vessels are able to approach the town; but the bay affords a commodious harbour to the largest ships, which may ride there in perfect security from every wind. Mobile, situated at the mouth of the river of that name, on a gently rising bank, is nearly a mile in length, and contains several good houses, which are chiefly built of brick, with a regular fortress also of brick, towards the lower end of the town. There are, besides, numerous forts and settlements, generally in the neighbourhood of Indian villages. The houses of Europeans are usually of brick, consisting only of one story, but built on an extensive scale, having generally three sides inclosing a large square area. The more ordinary habitations are formed of a strong cypress frame, which is filled with brick, and then plastered white, inside and out; or sometimes lathed, and then covered with a reddish well-tempered mortar, which gives them the appearance of brick walls.

The country of Florida, in its general aspect, is flat, sandy, and barren, on the sea shore; but upon advancing inland, it becomes very marshy, abounding in natural meadows. Thence it presents a rich and fertile appearance, especially on the banks of the rivers; and, for the space of 30 or 40 miles from the coast, there is scarcely to be seen a single stone weighing more than two or three pounds. The interior parts are more hilly, and covered with wood; but the surface is more stony, and the smaller size of the trees indicates a decreasing fertility in the soil. The soil is commonly a white sand, lying on a bed of white clay; in some places a dark grey, brown, or black loam, on a foundation of whitish marl, chalk, and testaceous limestone: in the plains of West Florida, the vegetable mould is often perfectly black, soapy, and rich, lying on a deep bed of chalk or shells.

Climate. The climate is various, and has been distinguished into two tracts, viz. the northern, which includes the continental and western part of Florida, and the southern, which comprehends almost the whole of the peninsula. In the latter district, the thermometer stands habitually, in summer, between 88° and 89° of Fahrenheit, in the shade: and, during the months of July and August, frequently rises to 94°. In all seasons, the sun is scorching hot at noon; and, in winter, it very rarely freezes, nor is the cold ever so severe as to injure even the China orange tree, the fruit of which is said to be there remarkably delicious. The air is pure and free from fogs, but the dew is generally excessive. In January, the weather is wet and stormy; in February and March, dry and clear; in July, thick, hot, and suffocating; but, from the end of September to the end of June, it is altogether inconceivably delightful; and then, says Volney, "there is not, perhaps, a finer climate in the world." The east side of the peninsula is hotter than the west; and, towards the southern point of the west coast, there are, from May to August, frequent squalls and tornadoes, but not of long continuance. On the east, or Atlantic side, the eastern trade wind prevails; but, on the west, or towards the Gulf of Mexico, there are cooling sea breezes from the north-west, through the whole season of summer. About the autumnal equinox, and during the two or three months following, violent storms and dreadful hurricanes frequently occur. In the northern climate, the winds are colder and more variable, the frosts in winter more severe, the temperature more changeable, and the fogs more prevalent, so as to occasion mouldiness, rust, and the deliquescence of salt, sugar, &c.; yet the town of St Augustine, where this dampness is very great, but where there are no adjoining marshes, is the healthiest place throughout these latitudes; and many persons from the Savannah resort thereto, as to a Montpelier. In both the tracts of climate, however, particularly in the more northern, there are great variations from heat to cold, making often a change of 30° upon the thermometer, in the space of twelve hours. From the end of June to the middle of October, the season of the heavy rains, combined with violent heats, fivers are very common, and are observed to be most obininate near the rice and indigo plantations. Persons who drink hard, and sleep in the open air, are very subject to tetanus; and all intemperate habits are found to be utterly ruinous to health in these provinces.

The vegetable productions of Florida are particularily deserving of notice, both for their wonderful variety and luxuriant growths. Nothing can exceed the majestic appearance of its towering forest trees, and the brilliant colors of its flowering shrubs. The pines, palms, oaks, cedars, and chestnuts, grow to an extraordinary height, and size. The laurels, especially the magnolias, are uncommonly striking objects, rising with erect trunks to the height of 100 feet, forming, towards the head, a perfect cone, and having their dark green foliage silvered over with large milk white flowers, frequently eight or nine inches in diameter. The live oaks, after forming a trunk from ten to twenty feet high, and from twelve to eighteen in circumference, spread their branches fully fifty paces on every side. The cypress, generally growing in watery places, has large roots like buttresses, rising around its lower extremity, then rearing a stem of eighty or ninety feet, throws out a flat horizontal top like an umbrella, so that often growing in forests all of an equal height, they present the appearance of a green canopy supported upon columns in the air. The dog-wood trees rise to the height of twelve feet, then spread their branches horizontally, which, meeting and interweaving with others on every side, form a shaly grove, so dense and humid, as completely to exclude the rays of the sun; and to suppress the growth of any other vegetable, thus presenting to the traveller a natural shelter, frequently extending for the space of ten miles without interruption. But the most beautiful of the forest tribe, is the tapering carica papaya, which rises to the height of twenty feet, with a stem perfectly straight, smooth, and silver-coloured, having a spherical top of leaves always green, and ornamented at once with flowers and fruits. Many rich fruits, particularly limes, prunes, peaches, and figs, grow wild in the forests, and grapes, vines, whose stems are often ten or twelve inches in diameter, climb around the trunks of the trees to their very tops, but those which produce the best fruit creep along close to the ground from one low shrub to another. Among the shrubs may be particularly mentioned a species of myrica, called the wax tree, which grows to the height of nine or ten feet, and produces a number of large round berries, covered with a coat of white wax, which is formed by the inhabitants into candles, harder and more lasting than those made of bees wax. Of the numerous flowering plants, we can only particularize a species of hibiscus, which, though a herbaceous plant, renewing its stem every year, yet grows to the height of ten or twelve
When A and and of considerable the is and but, remarkably the large species small feet, with a curium, in the lake, and rivers, feeding on the water-grass; and horses, running wild, it are kept in birds by the natives. They are extremely beautiful and sprightly; but of a small breed, and almost as slender in their form as the American roe-buck. Of the wilder tribes, there are the weasel, polecat, and lynx, which last is a very fierce little creature, preying upon young pigs, fawns and turkeys; foxes, of the small red species, which bark during the night, but move so precipitately, that they are seldom heard twice in the same spot; wolves of different colours, larger than a dog, generally assembling in companies, particularly during the night-time; bears, in considerable numbers, and of great strength, but scarcely ever known to attack human beings. When fat and full grown, they weigh from 500 to 600 pounds weight; and their flesh is greatly esteemed as food by the natives. Of birds, Bird besides many which are migratory, there are found stationary in Florida, vultures, hawks, rooks, jays, parrots, wood-peckers, pigeons, turkeys, herons, cranes, curlews, coromans, pelicans, plover, &c. A few of the more remarkable are the snake bird, a species of coromant of great beauty, which delights to sit in peaceable communities, on the dry limbs of trees, hanging over the lakes, with their wings and tail expanded, if cooling themselves in the air; and, when alarmed, they drop as if dead into the water, suddenly appearing again on the surface, at a great distance from the spot where they first sunk, but shewing only their long slender head and neck above the water, which gives them very much the appearance of a snake. The crying bird, a species of pelican, about the size of a large domestic hen, and of a speckled colour, with a short tail, having the longest feather in the middle, and the two outermost perfectly white, which the bird is accustomed, whenever he is disturbed, to flit out on each side with the quickness of lightning, uttering at the same time a very harsh and loud shriek. The wood pelican, a large bird, nearly three feet high when standing erect, feeding on serpents, frogs, and other reptiles, is generally seen solitary on the banks of the marshes and rivers, with his neck drawn in upon his shoulders, and his long crooked beak resting like a scythe upon his breast; this bird is supposed to approach the nearest to the Egyptian ibis. The painted vulture, of a white or cream colour, except the quill feathers of the wings, and the tip of the large tail feathers, which are black and dark brown or black, is seldom seen, unless when the deserts are set on fire, which sometimes happens from lightning, and is more regularly done by the Indians, to rouse the game; and then they gather from every quarter towards the burning plains, and alighting among the smoking embers, gorge their immense craws with roasted serpents, frogs, and lizards. The Creeks form their national standard with the tail-feathers of this bird, preserving them in their natural white colour, in peaceable negotiations, but drawing a zone of red beneath the brown tips when they go to battle. The great savannah crane, a very stately bird, about six feet in length from the toes to the extremity of the beak when extended, nearly five feet when standing erect, and eight or nine feet between the extremities of the expanded wings: they fly in detached squadrons, all rising and falling as one bird, and while they move their wings in flight with slow and regular strokes, the shafts and webs of their quill-feathers may be heard at a considerable distance in the air, creaking like the working of a vessel in a tempestuous sea.

Agricul-
pal produce. 

The principal vegetable productions regularly cultivated for the subsistence of the inhabitants, are corn, pulse, particularly beans, potatoes, pomeions, melons, rice, and a variety of esculent roots, particularly a species of arum, which is much cultivated in the maritime districts, and has a large turpin-like root, resembling when boiled or roasted the taste of the yam. Tobacco, cotton, and indigo, are raised in considerable quantities; and the last mentioned article, made in East Florida, is accounted equal to the best Spanish produce. Among the mineral productions of this province are found several kinds of precious stones, amethysts, turquoises, and lapis lazuli. Ochre, pit-coal, and especially rich iron ore, are very abundant. Near to New Smyrna, a thriving settlement on the Musquito river, is a vast hot mineral spring, issuing from a high ridge on the bank of the river, with great force, and in such abundance as to fill a circular basin, capable of holding for several hatches to ride in it. The water is of a sulphureous nature, and covers every immoveable substance deposited in it, with a pale bluish conglomum; but it is remarkably diaphanous, and the numerous fishes, which subsist in this tepid stream, are seen at a considerable depth with the greatest distinctness.

Animals.

The country is stored with creatures fit for the use of man, without producing many that are very formidable, either from their ferocity or strength. There are rabbits, squirrels of several species, (some of which are remarkably beautiful), racoons and opossums, which are accounted very delicious food; herds of deer and horned cattle, which are large and fat, but subject to extensive ulcersations in their thighs and haunches, sup-
The coast, sounds, and inlets, abound in excellent fish; and the inland lakes and rivers are, in some places, actually crowded with the finny tribe. Of these, the more remarkable are, the great brown spotted garr, from five to six feet in length when fully grown, whose impenetrable skin resembles a coat of mail, of which the scales are so sharp and strong, that the Indians use them as points to their arrows. The mud fish, about two feet long, the flesh of which is white and tender, but rather soft, and not much esteemed. The golden bream, or sun-fish, about eight inches in length, resembling the trout in shape, remarkably strong and ravenous for his size, and very delicious as food; the silver bream, and the black or blue bream, which are also extremely beautiful and abundant; the cat-fish, sting-ray, scale, flounder, spotted bass, sheeps-head, drum, Kc. and many other varieties, are found everywhere, even in the smaller ponds and open holes, in the utmost abundance. This multitude of fishes furnishes subsistence to an equally numerous brood of alligators, which are seen in all the rivers and lakes, in immense bodies, many of them more than 20 feet in length. A prodigious assemblage of them in the river St. John, was witnessed by Mr. Bartram pursuing the vast shoals of fish with which that river abounds; and his description of the scene will best convey an idea of their numbers, as well as of the prolific nature of the waters in Florida. "The river in this place from shore to shore, and perhaps near half a mile above and below me, appeared to be one solid bank of fish of various kinds, pushing through this narrow pass of St. John's into the little lake, on their return down the river; and the alligators were in such incredible numbers, and so close together from shore to shore, that it would have been easy to have walked across on their heads, had the animals been harmless. What expressions can sufficiently declare the shocking scene that for some minutes continued, whilst this mighty army of fish were forcing the pass! During this attempt, thousands, I may say hundreds of thousands of them, were caught and swallowed by the devouring alligators. I have seen an alligator take up out of the water several great fish at a time, and just squeeze them betwixt his jaws, while the tails of the great trout flapped about his eyes and lips ere he had swallowed them. The horrid noise of their closing jaws, their plunging amidst the broken banks of fish, and rising with their prey some feet upright above the water, the floods of water and blood rushing out of their mouths, and the clouds of vapour issuing from their wide nostrils, were truly frightful." Here may be mentioned, as belonging to the same genus with the alligator, the lizards of Florida, of which there are several species: the little green chameleon, about seven inches long, and very harmless; the striped lizard, called scorpions by the Americans, covered with small scales, vibrating their tail, and darting out their forked tongue when pursuing their prey; a small blue lizard, remarkably swift, with a long slender tail, which is subject to be broken off like that of the glass snake. There are several kinds of tortoises in the rivers and lakes, of which the most deserving of notice is the great soft-shelled tortoise, some of which, when full grown, weigh from 30 to 40 pounds, extremely fat and delicious, resembling very much in form and appearance the sea turtle. The whole back shell, except the vertebrae and ribs, is cartilaginous, and easily reduced to a jelly when boiled. These creatures bury themselves in the slushy bottoms of rivers and ponds, under the roots of aquatic plants, leaving an aperture just sufficient for the head to play through, for the purpose of seizing their prey, which they do with great rapidity, and frequently drag even the young water fowl from the surface. There is also the great land tortoise, called gopher, found only on the dry sand hills, on a light clay colour, and not easily distinguished from a stone. The upper shell, about 18 inches long and 12 broad, is exceedingly hard; and the animal on level ground, can easily carry a man standing on its back.

Of frogs there are various kinds, the largest of which is about 8 or 9 inches in length from the nose to the extremity of the toes, and has a loud hideous voice, inferior indeed to the bull frog of Virginia, but greatly resembling the grunt of a hog. Of the smaller kind, there are the bell frog, the voice of which is similar to the sound of a cow bell; another species of a beautiful green colour, which utter a noise like the yelping of young dogs; a still smaller tribe which infest the houses, whose voice is like that of young chickens; and an extremely diminutive class, called Savannah crickets, which may be seen in the rainy season clamouring like spiders upon the tall grass. There are red and black toads, the former of which are very large, weighing upwards of a pound, but no way venomous.

There are numerous kinds of snakes in Florida, but Reptiles little different from those which are found 'in the other southern provinces of the United States. The largest is the rattle-snake, which is commonly from four to six feet in length, and sometimes even eight or ten. With a single scratch of one of his fangs, lie is able to kill the largest animal, but is never known to strike unless first assaulted; nor can he creep faster than a man may walk, and may easily be killed with a single blow on the head or back, from a stick not thicker than a man's thumb. There are also the mecoasis snake, which abounds in East Florida, large as the rattle-snake, and said to be more formidable by being more apt to bite; the bastard, or ground rattle-snake, of small size, but extremely fierce and venomous; the green snake, a beautiful and harmless creature, about two or three feet in length, but not thicker than a man's little finger; the ribbon snake, of a clear vermilion colour, variegated with transverse zones of dark brown, very inoffensive, and generally found about old buildings; the chicken snake, very strong and swift, about six feet in length, but scarcely so thick as a man's wrist, a domestic kind of creature, innocent as a worm, easily tamed, and capable of being made useful for destroying rats, but apt at the same time to prey upon chickens; the bull snake, as long as the rattle-snake, uttering when irritated a loud hissing noise, but completely inoffensive with respect to mankind; the coach-whip snake, a beautiful and harmless creature, about six feet in length, but slender as a common walking stick, and tapering from the abdomen towards the tail like a switch, or long whip, remarkably swift, seeming at times to fly along the surface of the ground, touching it only with its lower extremity; the glass snake, of a bluish green colour, about two feet and a half in length, with a short belly, and great length of tail, which is so extremely fragile, that it breaks like glass by a gentle stroke of a light switch.

Incredible numbers of the small insects called ephemeral insects, more, cover the surface of the lakes and rivers, supplying abundant food for the birds, frogs, and fishes; and clouds of beautiful butterflies hover among the shrubs and flowers. Various flies of a more hostile character, harass the traveller and his horse in the hotter seasons; and particularly one species called the burning
Florida, *fly*, of a splendid green colour, and golden head, which
stings like the prick of a red hot needle, or a spark of
fire on the skin. *Gmme* and *mosquito* also are extremel
ly frequent and troublesome, especially on the sea coast,
and in the rice and indigo plantations; but they are
said to disappear in proportion as the land is cultivated.
There are said to be no bees in West Florida; but in the
east province they are sufficiently numerous.

Population. When Florida came into the possession of Great Bri-
tain, the greatest encouragement was given to settlers;
and at first considerable additions were made to its Eu-
ropean inhabitants. But their increase was extremely
slow, notwithstanding the salubrity of the climate, and
the advantages offered by government to the planters;
and, since the country was recuperated by the Spaniards,
its population and improvement are very imperfectly
known. The whole of the white population is calcul-
ated by Volney not to exceed 40,000; and the amount of
the Indian tribes residing within its territories can-
not be ascertained with any degree of accuracy.
Parties of the Chactaws and Chicasaws are occasionally seen
in the more western districts, between the river Mob-
ile and the Mississippi; but the more regular occu-
pants of the interior are the Muskegoses or Muscogulges,
generally called the Confederated Creeks, on account of
the rivulet's and swamps with which their territory abounds.
Their principal settlements are situated be-
tween the branches of the river Mobile and those of
the Appalachian, particularly on the borders of the
Costa and Falpose. These are generally distinguish-
ed by the name of Upper Creeks; and, in 1771, were
supposed to number 3500 warriors; but, as their coun-
try is connected rather with the province of Georgia,
we have already referred to that article for a fuller ac-
count of their character and manners. That part of
the same nation who inhabit the Florida, are called
the Lower Creeks, or Siminole. Directing their course
to the south in quest of a more plentiful country, they
completely extirpated the Yamasses, who were then in
possession of these fruitful regions, and in close alli-
cance with the Spaniards, and now form one people
with the remains of the tribes who were in alliance
with the conquered race. There are found, particular-
lly in East Florida, numerous monuments of apparent
antiquity, with the nature of which none of the pre-
sent Indians seem to have much acquaintance; and
which, therefore, render it highly probable that the
country was formerly occupied by a people more civi-
lized and skilled in the arts of life than the Yamasses,
Creeks, or any of the modern American tribes, known
to Europeans. These are pyramidal hills or artificial
mounts, erected near the sites of ancient towns, as to
command an extensive prospect of the adjacent coun-
try, and conjectured to have been intended as watch
towers, or places for sacrifice; vast tetragon terraces
adjoining to these mounts, supposed to have been the
foundations of fortresses; oblong sunken areas sur-
rounded by a bank, sometimes by two, one behind the
other, more elevated than the first, resembling amphitheat-
tres for the exhibitions of games or shows, and gen-
ernally appropriated by the modern Indians to the exec-
tion of their captives; artificial lakes or ponds, to
which spacious avenues run from the mounts. These
ancient remains were seen by Bartram on the east shore
of St John's River, at the entrance of the great Lake
George, on the opposite shore, on the bank of the Little
Lake, on Dunn's Island, a little below Charlotteville,
and on the west banks of the Musquitoe River, near New
Smyrna. The Siminole, who now inhabit these coun-
tries, are a more populous of people, and range at liberty
over the richest plains of both provinces. They find,
in the spontaneous productions of the soil, and in the
abundance of game which the forests afford, a superflu-
ity of subsistence; and secured in the midst of their
swamps from any sudden attack of hostile tribes, they have
nothing to occasion their disquietude, but the grad-
ual encroachments of the White people. They are re-
markably joyous and voluble in their dispositions; and
nothing can be more expressive of lightness of heart
than their whole visage, deportment, and motions.
They are fond of gambling, and spirituous liquors; and
amuse themselves, like children, in entreating, by the
most curiosities, to excite surprise and wonder.
They are the most active and expert hunters, and
by the sale of deer, bear, tiger, and wolf-skins, hon-
ey, wax, horses, &c. they procure their clothing and
domestic utensils from the White settlers. They are,
however, treacherous and unsteady, and being far re-
moved from the control of the upper Creeks, with whom
they are confederated, and whose government is
more regular, they are apt to pay little regard to treaties
of amity with the Whites, and to commit murders and
depredations on detached families who fall into their
hands. See Modern Univ. Hist. vol. xxxix.; Robert-
son's Hist. of America, vol. ii.; Bartram's Travels in
Carolina, Georgia, and Florida; Volney's Account of
the United States; Bernard Remans Concise Natural
and Moral Hist. of East and West Florida, published
in New York in 1776, a very scarce but highly interest-
ing production; and Hutchin's American Geography. (q)

FLORIS, FLORES, or ENDE, is the name of a large island in the eastern seas, situated to the east of Java,
between the 150th and 123rd degrees of East Longitude,
and the 8th and 9th degrees of South Latitude. It is
about 200 miles long, and has an average breadth of
36 miles. The interior of this island is very imperfectly
known. The inland parts are mountainous and woody,
and it contains a burning mountain of considerable
height. Towards the sea coast, the country is fine and
open. The principal place frequented by the English
in passing through the straits of Floris, is the village
of Laranouca, upon the island of Floris. Refreshments
for two or three ships can be obtained here, such as
goats, hogs, fowls, and fruits, buffaloes, and some turtle,
and water. In return for these, the natives will receive
gun-powder, musket balls, glass bottles, wine glasses,
white linen cloth, and all kinds of coarse cutlery.
Benzoin, ambergris, and small quantities of wax, are export-
ded from the island, and sandal wood in small quantities
may also be obtained. Many of the natives profess Chris-
tianity, and they generally hoist the Portuguese flag. The
Burmese language prevails over the greatest part of the
island. The Portuguese visited this island at a very
early period, and gave it the name of Floris; but there
is no reason to believe that they ever established a reg-
ii. p. 385; and Hamilton's East India Gazetteer. (u)

FLUENTS. See Fluxions.

FLUIDS. See Chemistry and Hydrodynamics.

FLUSHING, VLISSENGEN, or FLEISINGUE, is the
name of a seaport town of Holland, situated in the
island of Walcheren, on the north side of a branch of
the river Scheldt. The port lies between two moles,
that break the waves of the sea, which enters the town
by means of two canals, forming two basins. This
town defends the passage of the Scheldt and of all the
islands of Zealand. The Stadhous, which is built in
imon of that of Amsterdam, is a magnificent build-
ing. The position of the town, according to trigono-
metrical observations, is 53° 34' 57" West Long. and
North Lat. 51° 25' 42". See WAGHREN.

FLUTE Star, in Music, is a range of pipes in an
organ, so called, because the tone of them resembles
the English flute or flageolet. Their pitch is an octave
higher than the diapasons, or in unison with the prin-
cipal stop, but whose sounds are less soft and pleasing
than those of the flute stop. (e)

FLUTTERY, in Music, is a phenomenon attending
the sounding of a regular discord, made by two notes
that are diatomically related otherwise than as a concord,
as, 4, 16, 4, 16, &c. Before the completion of the
Rev. Mr. Liston's EUHARMONIC ORGAN, (see that article,)
it was very difficult to so exactly adjust or tune discord-
ant intervals, that this peculiar effect, very different
from the beats accompanying imperfect concords, could
be heard; and Dr. Robert Smith, who gave them this
name, was perhaps the first person who experimented
on, and investigated the theory of, these fluttering rough-
nesses of the discs when truly tuned. See his Har-
monics, Second Edit. p. 97. (e)

FLUXIONS.

The invention of the Method of Fluxions, as it is cal-
ced in this country, or the Differential and Integral
Calculus, as it is called by foreign mathematicians, goes
no further back than the 17th century; but the inquiries
which have led to it, must have occurred to Geometers
from the earliest period at which the science of geometry
was cultivated. It appears from the writings of Euclid
and Archimedes, that when the ancients considered cur-
viligne spaces, or the solids formed by the rotation of
curves, they established the truth of their propositions
by a peculiar mode of demonstration, which was indi-
rect, and more subtle and prolix than was used in ordi-
nary cases. The second proposition of the xxii. book of
Euclid's Elements, is an instance of this kind of demon-
stration. It is there proposed to prove, that circles
have to each other the ratio of the squares of their diam-
eters. The preceding proposition proves, that similar
polygons inscribed in the circles, have to each other
that ratio; and hence, by a mode of reasoning rather
artificial, although quite accurate, the truth of the pro-
position is proved to extend to the circles themselves,
by shewing, that the square of the one diameter can-
not be to the square of the other diameter, as the one
circle to a space either less, or greater than the other
circle.

Although the ancients chose this mode of demonstrat-
ing the truth of such propositions, yet it may well be
supposed, that they discovered them at first by a
more simple mode of reasoning. In the instance we
have quoted, as the ratio of similar polygons inscribed
in the circles is altogether independent of the number
of sides; and as the greater the number of sides, the
polygons became more nearly equal to the circles, from
which at last they may differ by less than any assign-
able quantity, it is easy thence to infer the truth of the
proposition. Here, however, there is a transition from
a polygon of a finite number of sides to the circle,
which is tacitly regarded as a polygon of an infinite
number of sides; now this is the very circumstance,
which in the end led to the invention of the method of
fluxions.

When, after a long period of darkness, the light of
science again shone forth in Europe, and the writings
of Euclid and Archimedes were studied, with a view to
detect the principles which had led to the discovery
of the truths which they contain, it was soon obser-
vated, that these Geometers had been more careful to
convince, than enlighten their cotemporaries; and that
however well the synthetic mode of demonstration
was adapted, to place the truth of a proposition beyond
doubt, yet it afforded little aid as an instrument of dis-
covery. It was no doubt this view of the ancient geo-
meter that induced Cavalieriius to depart from its rigour,
and invent his Method of Indivisibles, in which he con-
considered lines as composed of an infinite number of
points; surfaces as composed of an infinite number of
lines; and solids as made up of an infinite number of
surfaces. He appears to have possessed his theory in
the year 1629, and he published it in 1635 with this ti-
tle, Geometria indivisibilium continuorum nova quadam
ratione promota. The accuracy of his method was at-
tacked by Guldiman in 1640, and then he shewed, that
at bottom it was the ancient theory of Exкахutions, but
divested of its probability. In fact, these surfaces and
lines, of which Cavalieriius considered the ratios and the
sums, are no other than the little solids, or the inscri-
bred and circumscribed parallelograms of Archimedes,
sog numerous, as to differ from the figure, which is in-
cluded between them, by less than any given quantity;
but while Archimedes, when he demonstrates the ratio of
a curvilinear figure to another known one, employs
many words, and an indirect turn of demonstration;
the modern geomctcr, launching as it were into in-
finity, lays hold in imagination of the last term of these
continued divisions and subdivisions, which should in
the end annihilate the difference between the circums-
scribing and inscribed figures, and the curvilinear fi-
ure which they limit.

Roberval, in France, opened to himself the same ca-
areer of discovery as Cavalieriius had done in Italy. He
began by studying the writings of Archimedes; and his
method of resolving problems, relating to curviline-
al areas, differs from that of Cavalieriius, only in its
terms. His ambition to obtain a triumph over his ri-
vals, induced him to conceal his discoveries, until he
was anticipated by Cavalieriius' book, and thus justly
punished for his selfishness. He found a method of
determining the tangents of curves, which, however,
was inferior to another discovered by Descartes: Rob-
erval's method, in many cases, only substitutes one
difficulty for another, but Descartes applies to all alge-
braic curves, and in every case accomplishes the des-
ired purpose.

The obligations which philosophy and mathematics
ow under to Descartes, have been generally acknow-
elleed; but there is a feature in his character which
gives him a higher claim than any other geometer of
his time to the gratitude of posterity, and that is, his
carelessness to disseminate the knowledge of science, as
well as to extend its boundaries. Instead of hoarding
his discoveries, or concealing their source, as others had
done by tedious synthetic demonstrations in the man-
FLUXIONS.

He and moreover, the triangle, simple and method, by his communicative character, and the simple manner in which he has presented his researches.

Huygens first demonstrated Fermat’s two rules. Slüsser afterwards found a simple method of drawing tangents, which at bottom was but the enunciation of the calculus required by Fermat’s method; but disengaged from whatever was useless; and lastly, Barrow contrived his characteristic triangle, which in fact is the same as the triangle that measures the fluxions of the abscissa, the ordinate, and curve; and thus the method of finding the tangents of algebraic curves attained its last degree of simplicity.

While these improvements in the theory of tangents were going on, Gregory de S. Vincent, Hobcrval, and Pascal, made some progress towards a general solution of the problem of quadratures. This, however, was done by the method of the ancients, and that of indivisibles, and so does not bear directly on the history of the fluxional calculus, if we except the consideration of polygons of scales of Gregory de S. Vincent; or of a series of rectangles inscribed in, and circumscribed about a curve, which may have suggested the application of the fluxional calculus to quadratures.

It is in the arithmetic of infinites of Wallis, that we see the first application of algebraic calculation to quadratures, and this was founded on the method of indivisibles. Wallis considered series, and sought to express this sum by their first and last terms. He thus succeeded in finding the sum when the number of terms was infinite, and the last term may be reckoned as nothing. Considering, then, surfaces as formed of a series of lines, the terms of which follow a certain law, he found the expression for the surface by summing the series. The area of a triangle, for example, was determined by summing an arithmetical progression.

Wallis demonstrated, by his method, the fundamental rule for the quadrature of curves, the ordinate of which is proportional to any power whatever of the abscissa. This enabled him to square any curve, having its ordinate expressed by a series of monomials. His method of interpolation, by which the area of a curve was found, when its equation was in a manner comprehended between the equations of two other curves, to which his first method was applicable, deserves particular attention, because it was the germ of Newton’s most beautiful discoveries, and is at present the most important part of the theory of series. This method led him to a remarkable expression for the area of a circle. Wallis must be allowed to have contributed greatly to the progress of analysis, both by his own discoveries, and by having introduced the doctrine of series, which led to all the great discoveries of that period.

Neil and Van-Heuraet gave the first example of a curve that may be rectified, (one of the cubic parabolas.) Van-Heuraet’s method reduced the problem of rectifications to that of quadratures. Brunner and Mercator, proceeding in the path of Wallis’ discoveries, found the first series known for the rectification of the circle, and hyperbola. Brunner also first noticed continued fractions, and he showed that the fundamental principle employed by Neil in the rectification of curves, and that by which Mercator squared the hyperbola, were to be found in the works of Wallis.

Mercator published his Logarithmotechnia in September 1668, which contained his quadrature of the hyperbola; and soon after the book came out, Mr. Collins, secretary to the Royal Society, sent a copy to Barrow, at Cambridge, who put it into the hands of Sir Isaac Newton, and a fellow of Trinity College. Presently afterwards, viz. in July 1669, Barrow wrote to Collins, that a friend of his (Newton,) who had an excellent genius to these things, had brought him some papers, wherein he had set down methods of calculating the dimensions of magnitudes, like that of Mr. Mercator for the hyperbola, but very generally; as also of resolving equations; Barrow afterwards sent these papers to Collins, saying, that he presumed he would be much pleased with them, and requesting him to shew them to Lord Brunner. Their title was De analysi per aequationes numero terminorum infinitas. In this manuscript, the method of fluxions was first indicated, and rules deduced from it given for the quadrature of curves, to which it was observed, their rectification, and the determination of the quantity, and the superficies of solids, and of the centre of gravity, may be all reduced: moreover, the author there asserted, that he knew no problem relating to the quadrature or rectification of curves, to which his method would not apply; and that by means of it, he could draw tangents to mechanical curves; so, there can be no doubt but that then, Newton possessed the method of fluxions, and therefore he must be reckoned the first inventor. Indeed it appears that although his discovery was pro-mulated there for the first time, he had been in possession of it from about the year 1666, which was two years before Mercator published his quadrature of the hyperbola. And although the MS. memoir De analysi per aequationes numero terminorum infinitas, &c. prefixed to this method, rather than to demonstrate its accuracy, but there was enough to shew, that the author was aware of its great importance as an instrument of investigation, and that he had reduced it in some measure to the form of an analytical theory.

Barrow, Collins, and Oldenburg, (another Secretary to the Royal Society,) disseminated the analytical discoveries of Newton by their correspondence, and communicated them to several geometers on the continent, such as Slüsser, and Borelli.

In the year 1672, the celebrated Leibnitz, who afterwards also claimed the honour of the discovery of the method of fluxions, appeared for the first time upon the scene. Happening to be in London, he communicated to some members of the Royal Society, certain researches relating to the differences of numbers; but he was given to understand, that this subject had been already treated by Monton, an astronomer of Lyons; upon this, he turned his attention to the doctrine of infinite series, which, at that time, engaged all the mathematicians; and, in 1674, he announced to Oldenburg, that he possessed important theorems relative to the quadrature of the circle by series; and that he had
very general analytic methods. Oldenburg, in answer, intimated to him, that Gregory and Newton had also found methods, which gave the quadrature of curves, whether they were geometrical or mechanical, and which extended to the circle.

Leibnitz. The first direct communication which Newton had with Leibnitz, was in 1676. On the 18th June, in that year, Newton sent a letter to Oldenburg, which was to be shewn to Leibnitz: This contained his celebrated binomial theorem, which he appears to have known in 1669; and a variety of other matters relating to infinite series, and quadratures, but nothing directly relating to the theory of fluxions: and it is worthy of remark, that in this letter, "Newton speaks of Leibnitz with great respect; so that the suspicion which afterwards arose in his mind, that Leibnitz was not dealing fairly with him in respect of his discoveries, does not appear to have then existed. In a second letter from Newton to Oldenburg, to be also communicated to Leibnitz, he still speaks of his rival with respect; and he here, in compliance with a wish expressed by Leibnitz, explains the manner in which he found the binomial theorem. He also describes the properties of his method of fluxions, as well for the determination of tangents, as the quadrature of curves; but he conceals it under an anagram of transposed letters. Here we have positive evidence that Newton was now in possession of his calculus.

On the 21st June 1677, Leibnitz sent to Oldenburg, to be communicated to Newton, a letter containing the first attempts at a method which applied to every thing that could be done by that of Newton. This was his *Differential Calculus*. The death of Oldenburg, which soon followed, put an end to this epistolary correspondence; and seven years afterwards, viz. in 1684, Leibnitz published his method in the Leipscis Acts for October of that year, with this title, "*Nova Methodus pro maximis et minimis, itemque tangentibus, que nec fractas, nec irrationales quantitates moratur et singulare pro illis calculus genus*." Thus, in whatever way Leibnitz came by his calculus; whether he found it by the power of his own genius, which was certainly very great, or availed himself of Newton's discovery, which had in some measure transpired by his manuscript memoir, "*De analysi per equationes numero terminorum infinitas*," having been made known to many mathematicians, although not printed; certain it is, that his method was first given to the world; for Newton's method of fluxions only became generally known by the publication of his *Principia*, in the end of the year 1686.

Leibnitz enjoyed, without contradiction, the honour of being the inventor of his calculus, until the year 1699; and even Newton himself, in the first edition of his *Principia*, where he had occasion to give an example of his method of fluxions, allowed to Leibnitz the merit of his invention: For he says, "In the course of a correspondence, which ten years ago I carried on with the very learned geometrian Mr Leibnitz, having intimated to him that I possessed a method of determining *maxima* and *minima*, of drawing tangents, and resolving such problems, not only when the equations are rational, but also when they are irrational; and having concealed this method by transposing the letters of the following sentence, *An equation being given, containing any number of flowing quantities, to find their fluxions, and the contrary*, this celebrated man answered, that he had found a similar method, which he communicated to me; and which differed from mine only in the enunciation, and in the notation." To this, in the edition of 1714, was added, "and in the manner of conceiving the quantities to be generated."

It has been supposed that the claim of Leibnitz to the discovery would not have been called in question, if he had been just towards Newton: but in this respect he failed, and hence the origin of that quarrel which was carried on with such animosity between the British and foreign mathematicians. In some letters which he had written to persons in Britain, he had appeared to attribute to himself too exclusively the invention of his calculus, and this drew upon him some pointed remarks, respecting the prior claims of Newton. At length, a mathematician named Fatio de Duillier, who is said to have entertained a dislike to Leibnitz, on account of his having omitted to name him in an enumeration which he made of eminent mathematicians, asserted, in a short tract on the curve of swiftest descent, and the solid of least resistance, that Newton was the first inventor of the new calculus, and that he would leave to others to decide what Leibnitz, the second inventor, might have borrowed from the English geometry. To this attack Leibnitz gave a spirited answer, and complained to the Royal Society; and there the dispute rested for a time. Afterwards, when Newton's treatise on the *Quadrature of Curves*, and his * Enumeration of lines of the third order*, came out, in 1704, the Leipscis journalists gave an unfavourable account of it, and in effect said; that Newton had taken his method from that of Leibnitz, substituting fluxions for differences. This assertion called forth the indignation of the British mathematicians, and without doubt offended Newton himself. Accordingly, in 1708, Keill inserted in the Philosophical Transactions a paper, in which he stated formally, that Newton was the first inventor of the Fluxional Calculus, and that Leibnitz, in publishing it in the Leipscis Acts, had only changed the name and the notation.

Leibnitz thus accused of plagiarism, addressed a letter to Hans Sloane, Secretary to the Royal Society, requiring that Keill should retract what he had said: But far from this, Keill replied in a long letter to Hans Sloane, in which he enumerated the reasons that led him to conclude, not only that Newton had preceded Leibnitz in the discovery, but that he had given so many indications of his method, as to bring it within the comprehension of a man of even moderate capacity. This letter was sent to Leibnitz; who requested that the Royal Society should put a stop to the clamour of a person who was too young to know what had passed between him and Newton. The Royal Society judged that it would be proper to consult the original papers, and appointed a committee to select and examine them. The papers which they selected, were published by command of the Society, with this title, *Commercium Epistolicum de varia re Mathematica inter Celeberrimos presentes seculi Mathematicos, &c.* And to this was added the report of the committee, which was to the following effect: "That Mr Leibnitz was in London in 1675, and went thence to Paris, where he kept a correspondence with Mr Collins, by means of Mr Oldenburg, till about September 1676, and then returned by London and Amsterdam to Hanover, and that Mr Collins was very free in communicating to able mathematicians what he had received from Newton: That it did not appear that Mr Leibnitz knew any thing of the differential calculus, before his letter of the 21st of June 1677; which was a year after a copy
of Newton’s letter of the 10th December 1672 had been
sent to Paris, to be communicated to him; and about
four years after, Mr Collins began to communicate
that letter to his correspondents, in which letter, the
method of fluxions was sufficiently described to any
intelligent person: That Newton was in possession of his
calculus before the year 1669; and that those who had
reputed Leibnitz the first inventor, knew little or no
thing of his correspondence with Mr Collins and Mr
Oldenburg long before, nor of Newton’s having that
method above fifteen years before Mr Leibnitz began
to publish it in the Leipsic Acts: That for these reasons,
they reckoned Newton the first inventor, and were of
opinion that Mr Keill, in asserting the same, had been
in no wise injurious to Mr Leibnitz.

In this report, the committee cautiously avoided giv-
ing any direct opinion upon the only point on which
there could be any doubt, namely, whether Leibnitz
had invented the calculus for himself, or had availed
himself of the labours of Newton. The tenour of their
report seems to shew, that they were of the latter op-
inion. The Commercium Epistololum was circulated
with great care over Europe, with a view to vindicate
the claim of the British nation, to the most important
discovery that has ever been made in abstract scien-
tce.

It was not to be supposed that Leibnitz would quiet-
ly submit to this decision, so unfavourable to his pre-
tensions: He considered himself as grievously injured,
and threatened to answer it in such a manner, as to
confound his adversaries. This feeling must have arisen
from the insinuation, that he had stolen the inven-
tion; for, as to the right to priority of discovery, that
is, beyond doubt, in favour of Newton.

When this dispute was originally agitated, the natu-
ral feelings of patriotism, which protect nations against
the encroachments and unjust pretensions of each other,
prevented that cool discussion which is necessary for
the discovery of truth. The British mathematicians
were decidedly adverse to Leibnitz’s claims, while the
foreigners, on the contrary, supported them as
much acrimony as if it had been a dispute about a mat-
ter of faith rather than of testimony. Even Newton
himself, who, for a time, does not appear to have taken
an active part in the controversy, at last suppressed,
in the edition of his Principia, printed in 1726, the passage
he had inserted in the first edition, which admitted
that Leibnitz had discovered the calculus by his own efforts.
He probably would have done this in the earlier edi-
tion of 1713, if it had not been brought out in a pri-
ivate manner by Cotes and Bentley at Cambridge, while
he was at a distance, with whose conduct, on this occa-
sion, he was by no means pleased. It may be sup-
posed, that, in suppressing the passage, he was actuated
by a feeling of resentment for the undeserved abuse
that had been bestowed on his writings by the friends
of Leibnitz, and also by the unjustifiable conduct of
that philosopher himself.

It is perhaps impossible now to determine with cer-
tainty, whether there were just grounds for the suspicion
that Leibnitz had availed himself of Newton’s invention.
Montucla, in his History of Mathematics, vol. ii. p. 331,
2d edit, says, “There are only three places of the Com-
mercium Epistololum, which treat of fluxions in so clear
a way as to prove that Newton had found it before
Leibnitz, but too obscurely it seems to take from the
latter the merit of the discovery. One of these is in a let-
ter to Oldenburg, who had signified to Newton that Slus-
sius and Gregory had each found a very simple way of
drawing tangents. Newton replied, that he conjectu-
lated what the nature of that method was; and he gave an
example of it, which shews that he was in possession
of a method in effect the same as these two geome-
ters had found. He adds, that this is only a partic-
ular case, or rather a corollary to a method much
more general, which, without a laborious calculation,
applies to the finding of tangents to all sorts of curves;
unintelligent or mechanical, and that without being
obliged to free the equation from radicals. He repeats
the same thing, without explaining himself farther, in
another letter; and he conceals the principle of the
method under transposed letters. The only place where
Newton has allowed any thing of his method to trans-
pire, is in his Analysis per aequationes numero terminorum
infinitos. He here discloses, in a very concise and ob-
scure manner, his method of fluxions; but there is no
certainty that Leibnitz saw this essay. His opponents
have never asserted, that it was communicated to him
by letter; and they have gone no farther than to sus-
pect that he had obtained a knowledge of it in his in-
tercourse with Collins upon his second journey to Lon-
don. Indeed, this suspicion is not entirely destitute of
probability; for Leibnitz admitted, that in this inter-
view, he saw a part of the Epistolarry Correspondence
of Collins. However, I think it would be rash to pro-
nounce upon this circumstance. If Leibnitz had con-
fined himself to a few essays of his new calculus, there
might have been some ground for that suspicion. But
the numerous pieces he inserted in the Leipsic Acts,
prove the calculus to have received such improvements
from him, that probably he owed the invention to his
genius, and to the efforts he made to discover a method
that had put Newton in possession of so many beauti-
ful truths. This is so much the more likely, as from the
method of tangents discovered by Dr Barrow, the tran-
sition to the differential calculus was easy, nor was the
step too great for such a genius as that with which
Leibnitz appears to have been endowed.” In this op-
inion, we are disposed to agree with Montucla; and
we consider that we add to its weight by the fol-
lowing testimony in its favour, from one of the most
elegant writers and able critics of the present time:

The celebrated La Place having asserted, in his Philo-
sophical Essay on Probabilities, that Fermat was the true
inventor of the Differential Calculus; the writer to
whom we have alluded, in a review of La Place’s work,
says, “Against the affirmation that Fermat is the real
inventor of the differential calculus, we must enter a
strong and solemn protestation. The age in which that
discovery was made has been unanimous in ascribing
the honour of it either to Newton or Leibnitz; or, as
seems to us much the fairest and most probable opi-
nion, to both, that is, to each independently of the other,
the priority in respect of time being somewhat on the
side of the English mathematician. The writers of
the history of the mathematical sciences have given their
suffrages to the same effect. Montucla, for instance,
who has treated the subject with great impartiality, and
Bosset, with no prejudice certainly in favour of
the English philosopher. In the great controversy to
which this invention gave rise, all the claims were like-
ly to be well considered; and the ultimate and fair de-
cision in which all sides seem to have acquiesced, is
that which has been just mentioned. It ought to be on
good grounds, that a decision passed by such compe-
tent judges, and that has been now in force for a hun-
dred years, should all at once be reversed.” Edinburgh
The new calculus was not at first cultivated with that attention which its importance deserved; and, therefore, in order to renew the attention of mathematicians, Leibnitz, in 1687, proposed the following problem: "To determine the curve a heavy body ought to describe, in order to descend equally in equal times." Huygens was the first that showed what was the nature of the curve, but he did not indicate his method of solution. James Bernoulli also resolved the problem by the differential calculus, and published his analysis in the Leipsic Acts of 1690. About the same time, John Bernoulli, a younger brother of James, began his career as a mathematician: he studied the science, aided by his brother's instructions, and he contracted a friendship for Leibnitz, which continued until the death of the latter, in 1716. He made the calculus known in France, and gave lessons on the subject to the Marquis de l'Hôpital. Leibnitz and the Bernoullis resolved many new and difficult problems, which they proposed as challenges to the geometers of that period. They also determined the nature of the catenaria, (or curve formed by a chain or cord which hangs freely, but is fastened at its extremities), and the curve of swiftest descent, which had proved too difficult for Galileo, and the mathematical theories known in his time. A spirit of rivalry was excited between the two Bernoullis, and they waged a war of problems, each endeavouring to puzzle the other; this, although carried on with a degree of animosity on the part of John not at all becoming, was yet of advantage to the science, as it produced the celebrated *impermeable problems*, a class more difficult than any that had previously engaged the attention of mathematicians; although, indeed, Newton had resolved a problem of this kind in his *Principia*, when treating of the solid of least resistance. The calculus went on, improving continually; it was applied to the theory of *evolutes*, one of the most beautiful discoveries made by Huygens; but, with the exception of some pieces in the Leipsic Acts, there was as yet no work professedly on the subject; at length, the Marquis de l'Hôpital published his *Analyse des imfiment petits*, in 1699. John Bernoulli claimed the invention of the principal methods in this work, confidentially to Leibnitz in the l'Hôpital's lifetime, and publicly after his death. Indeed, l'Hôpital acknowledges in the preface his obligations to the two Bernoullis and Leibnitz, allowing them to claim as much of it as they pleased, and professing that he would be content with the remainder. l'Hôpital's book treats only of one part of the theory, viz. the differential calculus, which answers to the direct method of fluxions. He says he had intended to give a work on the integral calculus; that is, the inverse method of fluxions; but Leibnitz had informed him, that he was then preparing a treatise *De Scientia infiniti*, which he did not wish to anticipate. This work, however, never appeared. The first general theory in this part of the subject related to the integration of rational fractions, which John Bernoulli gave in 1702; but, indeed, he had indicated the method of integrating differential equations, by separating the variable quantities as far back as 1694. In 1707, Gabriel Manfredi, an Italian, gave an entire work, entitled, *De Constructione aequationum differentialium primi gradus*, which contained all that had been done down to that time relating to the integral calculus.

John Bernoulli composed a series of lectures on the integral calculus, for the use of his scholar and pupil, l'Hôpital; this was when he came to Paris in the year 1692. These are curious, as the earliest essays in this branch of the calculus, and valuable by their intrinsic merit. They would have formed an excellent sequel to l'Hôpital's work, but they were not published until 1742, when they appeared in the third volume of Bernoulli's works.

It is to be regretted that Newton did not accomplish a design he had formed in 1671, of publishing his method of fluxions, and its application; for, with the exception of what he himself had done, hardly anything appeared in England on the subject before the end of the century. David Gregory explained some of its principles and applications, in a treatise, *De dimensione figurarum*, printed in 1684. John Craig published a Craig treatise, *De curvarum quadraturis*, in 1693, which he afterwards enlarged and published again in 1718, with the title *De calculo fluentium*. De Moivre and Fatio gave solutions in the Philosophical Transactions of the problem concerning the solid of least resistance; the latter in 1695, and the former in 1699.

In the year 1703, George Cheyne, a Scottish mathematician and physician, published his *Methodus Fluxionum inversa*, Edin. 1703. The author committed some mistakes which were pointed out by De Moivre: he had also been wanting in justice to the mathematicians on the continent, and this exposed him to the animalversions of John Bernoulli. In the year 1704, a treatise of fluxions was published by Charles Hayes Gent. This, we believe, was the earliest work Hayes on the subject that was written in the English language.

It is remarkable that Newton himself should have been so slow in publishing anything relating to his calculus. The year 1699 must be considered as the epoch at which his numerous analytical inventions were first made generally known; but this was in the second volume of the works of Wallis. At length, however, in the year 1704, when he printed his *Opies*, he added to it, *Tractatus de Quadratura Curvarum*, in which he explains the principles of his method, applying it to quadratures. Besides, he composed the work he had originally intended, *On the method of Fluxions and Infinite Series*, with its application to the *Geometry of Curved Lines*. It was written in Latin, and Dr Pemberton once intended to have published it, with the author's consent, in his lifetime: This, however, was not done; and it was not printed until 1756, many years after Newton's death, when Colson translated it into English, and added to it a comment.

In enumerating the early improvers of the fluxional Cotes calculus, Cotes deserves particularly to be mentioned: He discovered a very elegant property of the circle, by which the fluxes of a certain class of rational fractions were determined by means of the trigonometrical tables and logarithms. Unfortunately for science this excellent mathematician died early in life. Newton had formed great expectations from him. His theorem forms the basis of his posthumous work, *Harmonia Mensuraria*, published in 1722, by his friend Dr Smith. The inventions of Cotes were extended and completed by De Moivre, in his *Miscellanea Analytica*, published in 1750. Dr Brook Taylor also holds a distinguished place in the higher class of those who extended the calculus. His *Methodus Incrementorum*, printed in 1715, contains in the second part many applications of fluxions to physico-mathematical problems. His theorem for the development of any function of a
binomial, leads to many beautiful applications of fluxions; and one of the greatest mathematicians in modern times, the late Lagrange, has made it the foundation of his theory of the calculus.

The science received considerable improvement from the mathematicians in Germany, particularly in that branch which relates to the fluxions of quantities, containing several variable quantities. The two Nicolas Bernoulli, one a son of James and the other a son of John Bernoulli, and Daniel Bernoulli, another son of John, gave, in the Leipsic Acts, and in the Petersburg Memoirs, a multitude of profound disquisitions relating to the calculus; and to these may be added the labours of their countryman Herman.

The dispute between the schools of Newton and Leibnitz tended to the improvement of the calculus, by the problems which each party proposed as challenges to the other. Thus Leibnitz, in order to feel the pulse of the English, as he expressed it, a short time before his death, proposed the problem of orthogonal trajectories, that is, curves which cut in a given angle a series of curves of the same given kind. Newton resolved the problem on the day he received it; but John Bernoulli did not consider his solution as complete, because he had not integrated the fluxional equation, but taken for granted that the manner of doing it was known. On the other side, Keill challenged Bernoulli, by name, to find the path of a projectile, moving in a medium, in which the resistance was as the square of the velocity. Bernoulli quickly resolved the problem, not only in that particular case, but also when the resistance was as any power whatever of the velocity. He then required that Keill should produce his own solution; but Keill had not resolved his problem himself, and in fact found it too hard. He therefore maintained a profound silence, and Bernoulli obtained a complete triumph over the English philosopher.

Taylor also proposed, as a challenge, a fluxion of a particular form to be integrated; this was addressed to all mathematicians not English. As John Bernoulli was understood to be particularly aimed at, he offered to wager fifty guineas that he could resolve Taylor's problem, and fifty more that he would propose a problem which Taylor should not resolve, but which he could resolve himself. Taylor did not accept this challenge; Bernoulli gave a solution of Taylor's problem in the Leipsic Acts.

The new calculi excited a controversy of a different kind, respecting the accuracy of their principles. These were attacked on the continent by Niewentiit, and Rolle; and defended by Leibnitz, Varignon, and Sarin. In England, Dr Berkeley, Bishop of Clonye, called in question, not only the logical accuracy of the reasoning employed to establish the theory of fluxions, but also the faith of mathematicians in general, in regard to matters of religion. He began the controversy in his work entitled the Minute Philosopher. But the principal attack was made in 1734, in The Analyst, or a discourse addressed to an Infidel Mathematician, (understood to be Dr Halley,) wherein it is examined whether the object, principles, and inferences of the modern analysis are more distinctly conceived than religious mysteries and points of faith. One of the best answers to the Bishop came from the pen of Benjamin Robins, in A discourse concerning the nature and certainty of Sir Isaac Newton's method of Fluxions, and of Prime and Ultimate Ratios. Berkeley, however, had some reason for his objections. The very concise manner in which the great inventor had promulgated his discovery, might leave room for a dispute about the accuracy of the terms. Instead of defending these, it was better to adopt a mode of explanation more intelligible, and consonant to the common methods of mathematical reasoning. This was done by Maclaurin, in his Treatise of Fluxions, (1742.) He has there placed the principles of the method upon the firm basis of geometrical demonstration; but his demonstrations are tedious, so that we fear few have patience enough to study the subject, as delivered in the first part of his work. The second, in which the subject is considered in the usual manner, and algebraic characters are employed, is very valuable, and indeed the whole work abounds with original views of the theories connected with fluxions, and it proves the author to belong to the highest class of mathematicians.

Before the publication of Maclaurin's treatise, Mr Thomas Simpson had given the first edition of his New Treatise of Fluxions, (1737.) He new modelled the work, and published it again in 1750. This was a very valuable work at the time it appeared; as far as it goes, is at the present time one of the best introductions to the method of fluxions in the English language.

Emerson's Doctrine of Fluxions came out in 1743. This has also been always much esteemed in England. It contains a great number of applications; but as it places the subject less within the reach of a beginner, Simpson's book is, we believe, more popular.

It is to the celebrated Euler that the calculus is indebted for its greatest improvements. Indeed these are far too numerous to find a place in the brief view which our limits allow us to give of the progress of the science; even the titles of his various memoirs would fill several of our pages; his more remarkable works will be given in the list of books relating to the subject in the conclusion. That branch of the calculus which treats of the higher class of problems, De maximis et minimis, such as the solid of least resistance, the curve of swiftest descent, &c. was first reduced by him to the form of a distinct theory, in his Methodus Inveniendi Linias Curvas Maximi Minimique Proprietas, sine solutis Problematibus Isoperimetri Iauii (1744.) This theory was improved and new modelled by Lagrange, and denominated the Method of Variations. It is a remarkable instance of Euler's candour, that he took up the subject a second time, and laying aside his own theory, treated it according to La Grange's views, employing also the same notation. Euler's writings on the analysis of infinites, and the differential and integral calculus, are a treasure of analytical knowledge, richer than was ever before produced by the labours of an individual.

A discovery made by an Italian mathematician, the Marquis Fagnano, or Fagnani, has contributed considerably to the improvement of a branch of the fluxional calculus. He found that it is always possible to assign two arcs of an ellipse, reckoned from one extremity of each axis, such that their difference may be expressed by algebraic quantities; and that any hyperbola has a similar property. This curious theorem, which has led to some remarkable transformations of fluxional formulae, appears to have been but little known in Britain, as we do not recollect to have seen it in any of the mathematical works published in this country until it was also found by our ingenious citizen, Mr Landen, who added to it another remarkable discovery, namely, that any hyperbolic arc may always
be rectified by means of two elliptic arcs. This theorem
was of great importance, because it reduced to elliptic
arcs all fluxions that had before been expressed by hy-
perbolic arcs. Legendre followed in the tract of Lan-
den's discovery, and shewed, in the Memoirs of the
Academy of Sciences of Paris, for 1770, that the recti-
fication of any ellipse may be reduced to that of two
circles of which have their eccentricities as small or as
great as we please.

It is a circumstance highly honourable to female ge-
nius, that we have to mention an excellent treatise on
this difficult branch of mathematics from the pen of a
lady; we allude to Analytical Institutions in four books,
written originally in Italian, by Dona Maria Gaetana
Agnesi, Professor of the Mathematics and Philosophy in
the University of Bologna. This work was first pub-
lished in 1748. A mathematician of great eminence,
Mr Bossut, translated the second volume of it into
French, and inserted it in his course of mathematics, as
the best treatise he could furnish on the differential and
integral calculus. And an English mathematician, Mr
Colson, (who translated Newton's Fluxions), translated
it also into English, having studied the Italian language
at an advanced period of life, for the express purpose
of making himself master of the work. The historian
of the mathematicians, Montucla, bestows great praise on
this extraordinary woman; and her own countryman,
Feiss, who has himself excelled so much both in pure and
mixed mathematics, calls her work Opus minimissimum,
ingeniocrassissimum et certe maximum quod ad hanc ex
fiemina alicujus calamo proderat. For an account of this
lady, see Agnesi.

The invention of the Arithmetic of Sines, which is
due to Euler, has contributed greatly to the improve-
ment of the calculus, and to its application to the phys-
ico-mathematical sciences. Indeed, to Euler we are
more or less indebted for almost every improvement it
has received. He first discovered the criterion by which
it may be determined whether a fluxional equation ad-
mits of an exact integral or not; but it was also found,
about the same time, by two French mathematicians,
Fontaine and Clairaut: this was about the year 1739
or 1740.

The method of Partial Differences, one of the great-
est improvements in the calculus, was the invention of
D'Alembert, who found it when he was inquiring into
the figure which a musical string assumes during its vi-
brations. The germ of the discovery may, however, be
traced to a memoir of Euler's in the Petersburg Com-
mentaries for the year 1744; and to him we are also in-
debted for the form of the theory and its notation.
Newton, in explaining the method of fluxions, con-
sidered all quantities as generated by motion, a line by
the motion of a point, a surface by the motion of a line,
a solid by the motion of a surface, &c. Leibnitz, on
the other hand, employed the consideration of infinitely
little increments, (infinitum petitum). Against both
these methods, objections have been urged. It has
been said, that motion is an idea quite foreign to pure
mathematics, and therefore it ought not to be employed
in establishing its doctrines; and still stronger objec-
tions have been urged against the introduction of in-
finitely small quantities into mathematics. Our ingeni-
ous countryman, Mr Landen, proposed to lay aside the
consideration of motion in explaining fluxions, and,
instead of the Newtonian theory, he proposed to sub-
stitute another, which he called the Residual Analyzis;
this was about the year 1760. His method has not been
followed, but his candour in getting the better of na-
tional prejudice in favour of Newton's method, has
procured him the approbation of foreign mathematici-
ans.

Lagrange, in the Berlin Memoirs for 1772, propo-
sed to shew, that the theory of the development of
functions into series, contained the true principles of
the differential calculus, independently of the considera-
tion of infinitely small quantities or limits; and he demon-
strated by this theory the theorem of Taylor, which he
regarded as the fundamental principle of the calculus,
and which had only been demonstrated by the help of
the calculus itself, or else by the consideration of in-
finitely little quantities. This is the view of the sub-
ject which he has given in his Theorie des Fonctions
Analytiques, published in 1792, and, at a later period,
in his Lecons sur le calcul des Fonctions. These works
have been much and justly admired, on account of the
luminous views they present of many important points
in the calculus. In explaining his method, the author
has employed a new mode of notation; but although
some of the best foreign writers have adopted his prin-
ципes, they have generally adhered to the old notation,
considering it more expressive and commodious than
that which was proposed.

Among the British mathematicians of later times,
who have cultivated this calculus, Dr Waring is con-
spicious. His writings are the only mathematical
works published in this country, until of late years,
that have kept pace with the improvements made in this
science on the continent. We fear they are less read
than they deserve, perhaps in consequence of their pe-
culiar style, and being composed in the Latin tongue.

In concluding this introduction, we mention, with
regret, the fact, that there is not a book in the English
language from which any thing like a tolerable know-
ledge of the fluxional or differential calculus, in its pre-
sent improved state, can be obtained. Such as wish
to study this science beyond its mere elements, must
have recourse to the writings of Euler, or to the French
Treatises. La Croix composed a work in three quarto
volumes, in which he professed to have collected, into
one point of view, all the improvements contained in
Euler's writings and in academical memoirs. A second
cdition, in which the work is somewhat enlarged, is
now printing, and two volumes have already come to
this country. There are other smaller works of great
merit also in the French tongue; these, as well as some
English treatises, which our limits will not admit of
our noticing more particularly, will be found in the fol-
lowing list of writers on this subject:

Newton, De Analyzi per equationes numero termino-
rum infinitas, published in the Commercium Epistolicum
in 1712, but circulated among his friends in MS. as ear-
ly as 1669.

Newton, Tractatus de quadratura curvarum, publish-
ed along with his Optics in 1704; also together with the
treatise De Analyzi, &c. by Jones, 1711.

Newton, Principia, Lib. II. Sect. II. Lem. 2. 1687.

Newton, The Method of Fluxions and Infinite Series,
1736.

Leibnitz, Nova methodus pro maximis et minimis item

The History of the Discovery of Fluxions is contain-
ed in the Commercium Epistolicum de varia re Mathe-
matica inter celeberrimos presentis seculi Mathematicos,
See Societatis Regiae in lucem editum, 1712, and the third volume of Opera Leibnitii, 1768, also a collection of pieces of M. Desmazieux, the works of Wallis, and Raphson's History of Fluxions.

The memoirs relating to the calculus, which have been published in the transactions of learned societies, are too numerous to admit of a particular description here. For these, the Bibliotheca Mathematica of M. Murhardt may be consulted: Also, the 7th volume of Reperatorium Commentationum, a societatis Litterarum editorum, published by M. Reuss. This volume, which is sold separate, contains the titles of all the mathema\tical memoirs inserted in the academical collections, and classified according to the different subjects.

The most beautiful applications which have been made of the calculus are to be found in the Principia of Newton, the Mechanica of Euler, the Mécanique Analytique of La Grange, and the Mécanique Celeste of La Place.
SECTION I.

FUNDAMENTAL PRINCIPLES OF THE THEORY OF FLUXIONS.

ARTICLE 1. In the branch of mathematical analysis, which is strictly called Algebra, quantities are distinguished into known and unknown; but, in some other branches, and particularly in the theory of fluxions, they are distinguished into constant and variable.

A constant quantity, is that which has always the same value.

A variable quantity, is that which may increase or decrease, and while it changes from one state of magnitude to another, passes through all the intermediate states.

Thus, in trigonometry, the radius of a circle is a constant quantity, and an arc of a circle, also its sine, tangent, and secant are variable quantities. In conic sections, the axes of the curves, and their parameters, are constant, and the abscissa and ordinates are variable.

2. It is usual to denote constant quantities by the first letters of the alphabet, a, b, c, &c. and variable quantities by the last letters, x, y, &c. so in the equation \( y^2 = ax + bx^3 \), \( a \) and \( b \) are constant, and \( x \) and \( y \) are regarded as variable, and \( a \) and \( b \) as constant.

A quantity which depends, in any way, upon another, so as to vary, according to the quantity as which it depends varies, is called a function of that quantity. If \( y = ax^2 + bx^3 + c \); or if \( y = \sqrt{\alpha^2 + bx^3} \) or if \( y = a + bx \), in each case, \( y \) is a function of \( x \); the quantities \( a, b, c \), are not considered, because they are supposed to be constant, and \( x \) alone to vary.

A quantity which depends upon two or more variable quantities, is also called a function of these quantities: Thus, if \( y = ax^3 + bx^6 \), then \( y \) is a function of \( y \) and \( x \).

A quantity may be considered as a function of another, provided it depend on it, although it be not directly expressed by that quantity, and even although the manner of expressing it is not known: Thus, in the equation \( x^2 + y^2 = axy \), \( y \) may be regarded as a function of \( x \), and, on the other hand, \( x \) as a function of \( y \); because the one may be expressed, in terms of the other, by the resolution of a cubic equation. Also, the roots of an equation, of the fifth degree, are to be regarded as functions of its coefficients, because they depend entirely on them, although the manner of expressing each root is not known.

3. Functions are distinguished into explicit and implicit. A quantity \( y \) is an explicit function of another quantity \( x \), when its value is given directly by that of \( x \), without the resolution of any equation. But it is an implicit function, when an equation must be resolved before its value can be found. Thus, if \( y = ax + bx^3 + c \), then \( y \) is an explicit function of \( x \). But if \( y \) be so related to \( x \), that \( y^2 + x^2 = axy \), in this case \( y \) is an implicit function of \( x \).

Functions are also divided into algebraic and transcendental. Algebraic functions are such as, when reduced to their proper form, consist of a finite number of terms, or admit of the relation of their indeterminate quantities being expressed by an algebraic equation. Transcendental functions, on the other hand, do not admit of the relation of the variable quantities being expressed by algebraic equations, composed of a finite number of terms; thus, if \( y \) be a logarithm, of which \( x \) is the number, that is, \( y = \log a \cdot x \); or if \( y = \pi \); or if \( y = \sin x \), then, in each case, \( y \) is a transcendental function of \( x \).

4. A clear notion of the nature of a function of a variable quantity \( x \) may be obtained by considering that quantity as the abscissa of a curve, and \( y \) the function, as the corresponding ordinate. Thus, if \( y = \sqrt{2x^3 - x^2} \); let a circle be described with a radius equal to \( a \), and at any point in the diameter, let a perpendicular be drawn to terminate in the circumference; then, the distance of the perpendicular from the extremity of the diameter, or the abscissa, being taken as the representative of \( x \), the perpendicular or ordinate, will represent \( y \), and the manner in which \( y \) varies will be understood by supposing the ordinate to move along the diameter, from one extremity to the other, thus giving all possible values to \( x \). A function of two or more variable quantities may in like manner be represented geometrically by one of the three co-ordinates of any point in a curve surface; the variable quantities on which the function depends being represented by the other two.

5. The hypothesis that a quantity may change from one state of magnitude to another, so as to pass through all the intermediate degrees of magnitude, gives rise to a property which belongs to all functions whatever, and which is the foundation of the theory of fluxions. The existence of this property may be proved in a general way; without any reference to particular functions. But as very general reasoning is not so convenient in establishing the principles of a science as an examination of particular cases, we prefer the latter method, at least in the outset of a branch of mathematics which is considered as somewhat difficult.

We begin, then, with the particular algebraic function \( u = x^2 \): Let us suppose that \( x \) changes to \( x + h \), and that corresponding to this change in the value of \( x \), the function \( u \) changes to \( u' \), then \( u' = x + h + x^2 + h^2 - 2x^2h + 3xh^2 + h^3 \); therefore \( \frac{u' - u}{h} = 2x + 3xh + h^2 \), that is,

\[
\frac{(x + h)^2 - x^2}{h} = 2x + 3xh + h^2,
\]

The first member of this equation is a function of two indeterminate quantities \( x \) and \( h \), which we suppose to be entirely independent of each other. Its numerator and denominator have the property of decreasing continually as \( h \) decreases, so that each may be as small as we please. As these are the corresponding increments of \( x^2 \) and \( x \), the second member is a general expression for the ratio of the increments. It is made up of two parts, one of which, \( 3xh \), is independent of \( h \), and the other, \( 6x^2h^2 \), has the property of decreasing as \( h \) decreases, and of vanishing altogether when \( h = 0 \); from which it appears, that although

* See a Memoir in the 13th Cahier of Journal de l'Ecole Polytechnique, entitled, Recherches sur quelques points de la Théorie des Fonctions dérivées, &c. By M. Ampère.

† Consulting brevity, we shall in general express any ratio by a fraction of which the numerator is the antecedent and denominator the consequent; thus, the ratio of \( N \) to \( D \) will be expressed by the fraction \( N \); and, consequently, the ratio of \( N \) to 1 will be expressed by \( N \).
the numerator and denominator of the function \( \frac{(x+h)^n - x^n}{h} \), or, in other words, the terms of the ratio expressed by that function, be supposed to decrease, yet the function can never be \( 0 \), but will approach to \( 3x^2 \); so that this quantity is a limit to the function, or, ratio, that is, a quantity to which it may continually approach, so as to differ from it at last by less than any assignable quantity.

The property which we have found to belong to the particular case \( \frac{(x+h)^n - x^n}{h} \), extends to the general function \( \frac{(x+h)^n - x^n}{h} \), \( n \) being any constant quantity whatever. In proving this, some writers proceed by the method of induction, and by deducing one case from another. Others employ the binomial theorem, supposing that theorem to be proved by the common operations of algebra. As we propose to deduce the binomial theorem, and others of a similar nature, from the fluxional calculus itself, we shall avoid all reference to it in establishing the principles, and give what we conceive to be a new and more elegant demonstration of the truth of the property in question. We shall in the first place, however, resolve the following

**Fundamental Problem.**

6. Let \( v \) be any positive quantity whatever, and \( p \) and \( q \) any two whole numbers, of which \( q \) is positive, and \( p \) either positive or negative. It is proposed to find two boundaries, between which the function \( \frac{v^p}{1-v^q} \) is always contained; that is, two expressions, one of which is always greater, and the other always less than the function.

Investigation. — Let us first suppose \( v \) to be less than unity, and the number \( p \) to be positive. Then because by division,

\[
\frac{1}{1-v} = 1 + v + v^2 + v^3 + \ldots + v^{p-1} + v^p
\]

we have

\[
\frac{1-v^p}{1-v} = 1 + v + v^2 + v^3 + \ldots + v^{p-1},
\]

the number of terms in the second member of this equation being \( p \). Now as the terms of the series go on continually decreasing from the first to the last, the first term multiplied by \( p \) will be greater than their sum, and the last term multiplied by \( p \) will be less. If the number of terms be considerable, the same thing will happen if we multiply the second term and the last but one by \( p \), and again the third and last but two, and so on. However, as we proceed, the results will differ less and less from the sum; and as there must be some quantity, which is a mean among all the terms, or which, when multiplied by their number, will give exactly their sum, if we suppose the two adjoining terms, which are, the one greater and the other less than this mean, to be \( v^m \) and \( v^{m+1} \); the sum of all the terms will be less than \( pv^m \), and greater than \( pv^{m+1} \); therefore, putting \( P \) for some quantity between \( m \) and \( m+1 \), the sum will be expressed exactly by \( pv^P \), and so we shall have

\[
\frac{1-v^p}{1-v} = pv^P, \quad \text{and} \quad 1-v^p = p(1-v^p).
\]

In considering the nature of the quantity \( P \), it appears to have these four properties:

1. Its value depends on the value of \( p \), and also on that of \( v \), so that it is a function of \( p \) and \( v \), which we suppose to be independent of each other.
2. It is always greater than 0, and less than \( p \).
3. If \( p \) be supposed to increase, then \( P \) also increases.
4. The quantity \( P \) increases slower than \( p \), so that if \( p \) is increased by an unit, \( P \) will not be increased by so much as an unit.

The first two properties are sufficiently evident. To prove the third and fourth, let us suppose that when \( p \) increases to \( p+1 \), then \( P \) becomes \( P^\prime \), thus we have,

\[
pv^P = 1 + v + v^2 + \ldots + v^{p-1}, \quad \text{(to } p \text{ terms)} \]

\[
(p+1)v^P = 1 + v + v^2 + \ldots + v^{p-1} + v^P, \quad \text{(to } p+1 \text{ terms)}.
\]

Let the first of these two series be denoted by \( N \); then we have evidently

\[
pv^P = N, \quad (p+1)v^P = N + pv^P,
\]

and hence, dividing the corresponding members of these equations the one by the other, we get

\[
\frac{(p+1)v^P}{N} = \frac{p+1}{N} + \frac{pv^P}{N}
\]

Now we have evidently

\[
\frac{p}{N} = \frac{v^P + v^P + v^P + \ldots + v^{p-1}}{1 + v + v^2 + \ldots + v^{p-1}}
\]

\[
\frac{p}{N} = \frac{1 + v + v^2 + \ldots + v^{p-1}}{1 + v + v^2 + \ldots + v^{p-1}}
\]

Then, as \( v \) is less than unity, the numerator of the first of these two expressions is manifestly less than its denominator, and the numerator of the second is greater than its denominator; therefore, the first fraction is less than unity, and the second greater; so that

\[
\frac{pv^P}{N} < 1, \quad \text{and} \quad \frac{p}{N} > 1;
\]

and hence, from equation (2),

\[
(p+1)v^{p-1} < p+1, \quad \text{and} \quad (p+1)v^{p-1} > 1 + pv^P;
\]

but \( v \) being less than unity, \( 1 + pv^P + pv^P \), that is, \( 1 + pv^P + (1 + p)v \); therefore, also

\[
(p+1)v^{p-1} > 1 + (p+1)v.
\]

From these expressions it appears, that

\[
v^{p-1} < 1; \quad \text{and} \quad v^{p-1} > v;
\]

and hence, by multiplying the quantities on each side of the sign of inequality by \( v^p \), we have

\[
v^{p-1} < v^p; \quad \text{and} \quad v^{p-1} > v^p+1.
\]

As \( v \) is by hypothesis less than unity, we may conclude from the first of these expressions, that \( P^\prime \) is greater than \( P \); and from the second, that \( P^\prime \) is less than \( P+1 \). Thus it appears, that the new value of \( P \), which corresponds to \( p+1 \), is greater than its former value, but that it does not exceed its former value by so much as

* Here we take for granted the obvious principle, that if a variable quantity pass from one state of magnitude to another without becoming infinite, it must successively have all intermediate degrees of magnitude.
1, and these are the two properties of the quantity P, which we proposed to demonstrate.

Since it appears from Equation (1), that when p is any positive integer number, then

$$1 - v^p = p (1 - v)^p,$$

So also q being any other integer number, there must be a corresponding quantity Q, such that

$$1 - v^q = q (1 - v)^q,$$

where Q must have the same properties relatively to q that P has relatively to p; therefore, by dividing the one of these expressions by the other, we get

$$\frac{1 - v^p}{1 - v^q} = \frac{p}{q} v^{q - q}. \quad (3)$$

Let us suppose, for an instant, that p and q are equal, then, P and Q will also be equal, and each will be less than p or q. Now, let p be supposed to increase, then P will also increase; but as it does not increase so fast as p, the excess of p above Q will not increase so fast as the excess of p above q, and so P - Q will always be less than p - q. In like manner, if p were supposed to decrease, in which case p - q and P - Q would be both negative, it will appear that the negative quantity P - Q would not increase so fast as the negative quantity p - q, so that in every case P - Q will be between 0 and p - q.

Let z denote some positive quantity that is less than unity; then, as we may assume that p - q : P - Q :: 1 : z, we have P - Q = z (p - q). As z depends on p and Q, and these again on p, q, and v; it follows, that z is a function of p, q, and v. It is 0 when p = q, but in every other case it is a positive quantity, less than unity. By substituting z (p - q) for P - Q, we have now

$$\frac{1 - v^p}{1 - v^q} = \frac{p}{q} v^{q - q} \cdot z (p - q).$$

Let v = \frac{1}{u}, so that v being less than unity, u will be greater than unity. Instead of v, let \frac{1}{u} be substituted in the formula just now found, and it becomes

$$\frac{u^{p-1}}{u^{q-1}} = \frac{p}{q} \left(1 - \frac{1}{u} \right)^{u (q - p)}.$$

As z is some quantity between 0 and 1, so also $1 - \frac{1}{u}$ will be between 0 and 1; therefore, our formula, which has been investigated upon the hypothesis that v is less than 1, is also true when v is greater than 1.

We have hitherto supposed p to be a positive quantity; but to include in the formula the case of p being a negative quantity, let both sides of the equation be multiplied by $v^{-p}$, and we have

$$1 - v^p = -p v \cdot z (p - q) - q.$$

Assume now $z (p - q) = -p = z' (p - q)$, and then $x' = z (p - q) + P$: hence, as all possible values of z are included between 0 and 1, so, all possible values of z' will be included between $P \times (p - q) - P$ and $-P \times (p - q) - p$: which is, that between $\frac{P}{p+q}$ and $\frac{-p}{p+q}$; but, by hypothesis, p and q are positive quantities; therefore these fractions are positive quantities less than unity, and consequently their values are between 0 and 1; and so we have

$$\frac{1 - v^p}{1 - v^q} = -p v^{q (p - q)} - q.$$

$z'$ being a quantity between 0 and 1; and here it is manifest, that if $p'$ be put instead of $-p$, the second member of the equation will have the same form as before.

Upon the whole, then, it appears, that v being any positive quantity whatever, and $p$ and $q$ any two whole numbers, of which q is positive, and p either positive or negative, we have always

$$\frac{1 - v^p}{1 - v^q} = \frac{p}{q} v^{q (p - q)}, \quad (A)$$

and here z is a certain quantity, in which every case is of an intermediate magnitude between 0 and 1; and in the case of p being a negative number, is contained between the narrower limits of $\frac{-p}{p+q}$, and $\frac{-p}{p+q}$. And thus we have a complete solution of our problem.

We now return to the function which expresses the ratio of the corresponding increments of x and $x$, $n$ being any quantity whatever. Supposing $x$ to change its value, and become $x + h$, then $x'$ becomes $(x + h)'$, and so the expression for the ratio of the increments is

$$\frac{(x + h) - x}{h} = v.' \quad \frac{x + h}{h} = v.$$

As we are at liberty to suppose q any number we please, it may evidently be assumed such a positive integer that q shall be a positive or negative integer. Let $n q = p$, and then by formula (A), last article, we have

$$\frac{v^n - 1}{v^{q-1}} = \frac{p}{q} v^{p (p - q)} = n \left(\frac{v}{q}\right)^{z (n - 1)},$$

and consequently,

$$\frac{(x + h) - x}{h} = n \begin{bmatrix} x + h \end{bmatrix} z (n - 1), \quad (B)$$

and as, in formula (A), z denotes some function of v, p, and q, the value of which is always greater than 0, and less than 1, and from here z denotes some function composed of x, h, and n, which is always of an intermediate magnitude between 0 and 1.

This formula shows distinctly the important analytical fact, that the expression for the ratio of the increments of x and x has always a finite value, whatever be the magnitude of h, the increment of x. Moreover, it gives us immediately two boundaries to that value; for, as z cannot be so little as 0, nor so great as 1, it follows that $z (n - 1)$ cannot be so little as 0, nor so great as n - 1, therefore the value of the expression

$$\begin{bmatrix} x + h \end{bmatrix} z (n - 1),$$

must always be between 1 and

$$\begin{bmatrix} x + h \end{bmatrix}^{n-1}, \quad \text{and that of the general expression for the ratio, between} \ n \begin{bmatrix} x + h \end{bmatrix}^{n-1}, \text{and} \ n \begin{bmatrix} x + h \end{bmatrix}^{n-1} \begin{bmatrix} x + h \end{bmatrix}^{n-1} = n \begin{bmatrix} x + h \end{bmatrix}^{n-1}.$$

The formula also shews, that there is a limit to which the expression for the ratio approaches as h decreases;
for then the fraction \( \frac{x+h}{x} \) approaches continually to unity, and as the boundaries to the value of the exponent \( x(n-1) \) remain unchanged, the function \( \left\{ x(x+h) \right\} x(n-1) \) will continually approach to unity, and the general expression for the ratio to \( n x^{n-1} \), which is evidently a limit to its value, because the expression \( \left\{ x(x+h) \right\} x(n-1) \) may differ less from unity than by any assignable quantity.

We have seen that the expression for the ratio is always between \( n x^{n-1} \) and \( n (x+h)^{n-1} \). These two expressions may be included in this one, \( n (x+h)^{n-1} \), where \( h' \) is put for a certain quantity greater than \( 0 \), and less than \( h \). We may therefore express the ratio otherwise, thus:

\[
(x+h)\frac{n-x}{h} = n (x+h)^{n-1} \quad (B')
\]

and in order to have the two boundaries to its value, we have only to give to \( h' \) its two bounding values, viz., \( 0 \) and \( h \). This is another formula, which shews also, in a very distinct manner, the properties of the expression of the ratio.

From this last formula, we have

\[
(x+h)^n - x^n = n (x+h)^{n-1} \; h;
\]

and as similarly,

\[
(x+h)^{n-1} = x \; x + (n-1) (x+h)^{n-1} \; h',
\]

where \( h' \) denotes some quantity between \( 0 \) and \( h' \), and consequently between \( 0 \) and \( h \); we have, by substituting for \( x (x+h)^{n-1} \) its value,

\[
(x+h)^n - x^n = n x^{n-1} + n (x+h)^{n-1} \; h' + u \; (n-1) (x+h)^{n-1} \; h'
\]

and therefore

\[
(x+h)^{n-1} - x^{n-1} = n x^{n-1} + n (x+h)^{n-1} \; h'.
\]

This expression for the ratio is composed of two parts, one of which, \( n x^{n-1} \), is entirely independent of the increment \( h \), and the other \( n (x+h)^{n-1} \) is a function of \( x \) and \( h \), which can evidently never be infinite while \( h \) has a finite value, but which vanishes when \( h=0 \), because of its factor \( h' \), when \( h=0 \). We may denote this second part of the expression simply by \( H \), and then the ratio may be otherwise expressed thus,

\[
\frac{x+h}{h} = n x^{n-1} + H, \quad (B')
\]

\( H \) being a function of \( x \) and \( h \), which vanishes when \( h=0 \), and from this expression the properties of the ratio may likewise be deduced. Hence also

\[
(x+h)^n - x^n = n x^{n-1} + H h.
\]

8. The property which we have demonstrated to belong to the function \( x^n \) enables us to prove that every algebraic function whatever, of a variable quantity \( x \), has a corresponding property. Let

\[
u = A x^n + B x^m + C x^{n-1} + \&c.
\]

be any integral algebraic function of \( x \), and let \( u' \) denote the new value of \( u \) when \( x \) becomes \( x+h \); that is, let

\[
u' = A (x+h)^n + B (x+h)^m + C (x+h)^{n-1} + \&c.
\]

Then because \( x+h \)?\( x \), \( x^n \) becomes \( (x+h)^n \), \( (x+h)^m \), and so on, we have

\[
u' = A (x+h)^n + B (x+h)^m + C (x+h)^{n-1} + \&c. + A H h + B H h' + C H h'' + \&c.
\]

Let the quantity \( \Lambda H + \&c. + \Lambda H h + \&c. \) which vanishes when \( h=0 \), be denoted by the single letter \( H \), then putting \( u' \) for \( A x^n + B x^m + \&c. \) we have

\[
u' = u' + (Am x^{n-1} + B m x^{m-1} + C m x^{n-1} \&c. + H h) + H h, \quad \text{and hence}
\]

\[
u' = u' = \frac{A m x^{n-1} + B m x^{m-1} + \&c.}{H h}.
\]

Here it appears that the expression for the ratio \( \frac{u}{h} \) has precisely the same property as has been found to belong to the ratio \( \frac{x+h}{h} \); it is composed of two parts, one a function of \( x \) only, and the other a function of \( x \) and \( h \), which vanishes when \( h=0 \).

The fractional function

\[
u = \frac{A x^n + B x^m + \&c.}{a x^n + b x^m + \&c.}
\]

has the same property; for by the substitution of \( x+h \) instead of \( x \), the numerator becomes

\[
A x^n + B x^m + \&c. + (m A x^{n-1} + m B x^{m-1} + \&c.) H + H h.
\]

and the denominator becomes

\[
a x^n + b x^m + \&c. + (a x^{n-1} + b x^{m-1} + \&c.) H + H h.
\]

Put \( A x^n + B x^m + \&c. = N \),

\[
m A x^{n-1} + m B x^{m-1} + \&c. = N' \]

and we have

\[
u' = \frac{N + N' h + H h}{D + D' h + H h}
\]

This expression, by actual division, is easily transformed to

\[
\frac{N + N' h + H h}{D + D' h + H h} = \frac{N}{D} \frac{N' + N D'/D}{D} + H.
\]

As the quantities \( D, N' \), and \( D' \) are all independent of \( h \), it is manifest that, in this case, the ratio has the same property which we have shewn to belong to it in the others.

9. The determination of the ratio of the increments of logarithmic and exponential quantities, according to the plan we have laid down, requires that we resolve this other

**Problem.**

Let \( b \) and \( x \) denote two positive quantities, neither of which is unity, and let \( b \) be constant, and \( x \) variable. Also let \( u \) be such a function of \( x \), that \( x = b \). It is proposed to find two boundaries to the values of \( u \); that is, two expressions, one greater and the other less than \( u \).

**Investigation.**—Let \( m \) and \( n \) denote any two given numbers. Then, whatever be the values of the quantities \( x \) and \( b \), provided they are both greater than unity, it will always be possible to find two whole numbers \( p \) and \( q \), and a positive quantity \( v \), such that

\[
v = \frac{1}{x}, \quad v = \frac{1}{n}.
\]

For, in order to determine them, we have by the theory of logarithms,

\[
p \log v = \frac{1}{n} \log x, \quad \text{and} \quad q \log v = \frac{1}{m} \log b,
\]

and therefore

\[
p = \frac{m \log x}{n \log b}.
\]
Hence $p$ and $q$ may be any two whole numbers, as great as we please, that have to each other the ratio of $m \log x$ to $n \log b$, which indeed is incommensurable, but may be expressed by numbers as near to perfect accuracy as we choose.

The remaining quantity $v$ will be found from the equation,

$$ \log v = \frac{1}{mp} \log x; \quad \text{or this, } \log e = \frac{1}{mq} \log b. $$

Now as by hypothesis $x = b^n$, and by assumption $x = b^m$, and $b = e^{\log b}$; therefore $v^m = v^q$, and hence $p = q$.

Also, since $v = x^t$ and $v^t = b^m$, therefore

$$ v^t - 1 = \frac{1}{b^m}. $$

Let these values of $v^t, v^t - 1, v^t - q, \text{ and } v$ be substituted in the formula

$$ \frac{v^t - 1}{v - 1} = \frac{p}{q} v^{t(q-p)}, $$

which was investigated in Art. 6. and it becomes

$$ \frac{a}{b} = \frac{n}{m} \frac{x^t}{b^m}; $$

and hence,

$$ u = \frac{b^m}{n} \frac{x^t}{m} \frac{n(x^t - 1)}{m(b^n - 1)}. \tag{C} $$

where $m$ and $n$ are, as we have already observed, quantities of any magnitude whatever; and $x$ is some quantity, always of an intermediate magnitude between $0$ and $1$.

This formula exhibits elegantly the boundaries to the value of $u$; for as $x$ can never be so small as $0$, nor so great as $1$, if we put $x = 0$ and $x = 1$, we shall obtain two expressions, one of which is greater, and the other less than $u$. These boundaries are

$$ n(x^t - 1) \text{ and } \frac{b^m}{n} \frac{x^t}{m} \frac{n(x^t - 1)}{m(b^n - 1)}. $$

They are remarkable on account of their involving two arbitrary quantities $m$ and $n$, which have no apparent connection with the function they serve to express. It also appears, that the bounding values of the function are to one another as $b^n$ to $x^t$; now as we are at liberty to give as great values to $m$ and $n$ as we please, this ratio may have any degree of nearness to a ratio of equality: Hence it appears, that the quantity $u$ is a limit, to which its two boundaries and the intermediate expression$$ \frac{b^m}{n} \frac{x^t}{m} \frac{n(x^t - 1)}{m(b^n - 1)} \text{ continually approach, as } m \text{ and } n \text{ are supposed to increase, and to which they may come nearer than by any assignable difference, and thus we have a complete solution of our problem.} $$

10. If we suppose $b$ to be the basis or radical number of a system of logarithms; then, in the equation $x = b^n, u$ is the logarithm of the number $x$. (Algebra, art. 380.) We have, therefore, from formula (C) this remarkable expression for the logarithm of a number:

$$ \log x = \frac{1}{m} \frac{x^t}{b^n} \frac{1}{n} (x^t - 1), \tag{D} $$

$z$ being some quantity contained between 0 and 1, and $m$ and $n$ any numbers whatever.

As we may suppose $m$ and $n$ to be as great as we please, we can make $\frac{z}{m}$ and $\frac{n}{n}$ each as nearly $= 0$, and consequently, the factor $\frac{1}{m}$ as nearly $= 1$ as we please.

In effect, therefore, we may consider, that

$$ \log x = \frac{(x^n - 1)}{m(b^n - 1)} \tag{E} $$

provided we do not limit the magnitude of the $m$ and $n$, but regard them as greater than any assignable numbers. Under either of these forms the expression for the logarithm of a number is valuable, because it identifies logarithmic and exponential expressions with common algebraic quantities.

11. Perhaps, it may be doubted whether such an expression as $n(x^t - 1)$, or $m(b^n - 1)$ admit of any definite value, on account of the indefinitude of the numbers $m$ and $n$. To remove this difficulty, we shall resolve this third

**Problem.**

Let $v$ be any positive quantity, and $u$ any very great number, or rather a number greater than any assignable number: it is proposed to transform the expression

$$ n(x^t - 1) $$

into another that shall be free from the indefinite quantity $u$: and also to calculate the value of the expression, in some particular case; for example, when $u = 10$.

**Solution.**—Let $V$ and $V'$ be two functions of $v$, so related to each other, that $2V' = V + 1$: Then $2(V' - 1) = V - 1$, and $V' = V + 1$; but

$$ V' = \frac{V + 1}{V - 1} + \frac{V - 1}{V + 1} \tag{V} $$

as will appear by bringing the terms in the second member of the equation into a single fraction. Hence we have this identical equation. *

$$ V' = \frac{V + 1}{V - 1} + \frac{V - 1}{V + 1} + \frac{1}{2} $$

An identical equation is so called, because it may be changed into another which shall express merely that a certain quantity is equal to itself. The equation $\frac{1}{x-1} = \frac{1}{x-1} \frac{1}{x+1}$ is of this kind, as will appear by reducing the terms in its second member to a common denominator. An identical equation differs from a common algebraic equation, such as $u^2 - 3u + 2 = 0$, in respect that the latter holds true only when $v$ has certain particular values, which, in the present case, are $v = 1$ and $v = 2$; but the other holds true when $v$ has any value whatever. Many geometrical theorems, when expressed by algebraic symbols, are identical equations. The fourth proposition of the second book of Euclid’s Elements produces this, $(x + y)(x - y) = x^2 - 2xy + y^2$; and the ninth and tenth produces this other, $x + y = (x + y)^2 = \frac{(x + y)^2}{2}$. In these $x$ and $y$ may have any magnitude whatever.
With a view to abridge, put $l$ for $V_{n-1}$ and similarly $l'$ for $V_{n-1}^+$, and, consequently, $\frac{1}{l}$ for $V_{n}^+$ then the formula may be expressed thus:

$$\frac{1}{l} = \frac{1}{4l} + \frac{l'}{4} + \frac{1}{4}$$

(1.)

Let us now suppose that $V'$, $V''$, $V'''$, &c. to $V^{(m)}$ ($m$) denoting the number of accents over the last term) are a series of quantities each formed from that before it, exactly as $V'$ is from $V$, or so that

$$2V = V' + 1, 2V'' = V' + 1, 2V''' = V'' + 1, \text{ &c.}$$

and let the fractions $\frac{V''}{V'}$, $\frac{V'''}{V''}$, &c. to $\frac{V^{(m)}}{V^{(m-1)}}$

be briefly denoted by $t^r$, $t''$, &c. to $t^{(m)}$, then from formula (1) we derive the following series of equations:

$$\frac{1}{l} = \frac{1}{4l} + \frac{l'}{4} + \frac{1}{2}, \quad \frac{1}{l'} = \frac{1}{4l'} + \frac{l''}{4} + \frac{2}{4}, \quad \frac{1}{l''} = \frac{1}{4l''} + \frac{l'''}{4} + \frac{2}{4}, \quad \text{&c.}$$

By adding the corresponding members of these equations into two sums, and rejecting what is common to both, we find

$$\frac{1}{l} = \frac{1}{4l} + \frac{l'}{4} + \frac{l''}{4} + \frac{l'''}{4} + \frac{l^{(m)}}{4} + \frac{1}{2}$$

(2.)

Now, the numeral series being a geometrical progression, of which the first term is $\frac{1}{2}$ and last $\frac{1}{24}m^{m-1}$, and common ratio $\frac{1}{4}$, its sum will be $\frac{2}{3} - \frac{1}{24}m^{m-1}$; therefore, after substitution and transposition, we find

$$\frac{1}{l} = \frac{2}{3} + \frac{1}{2} + \frac{1}{24} + \frac{1}{24} + \frac{1}{24} + \frac{1}{24} + \frac{1}{24} - \frac{1}{24}$$

Let us now assume that:

$$2V = v + \frac{1}{v}$$

Then $2(V + 1) = v + 2 + \frac{1}{v} = \left(\frac{1}{v} + \frac{1}{v^2}\right)^2$; but

$$2(V + 1) = 4V''', \text{ therefore,}$$

$$2V = v^2 + \frac{1}{v^2}.$$
Since, \( \frac{1}{n} \) can only be expressed by 0, we have \( v^2 + 1 = v + 1 + 1 = 2 \), and so the expression \( \left\{ \frac{v^2 + 1}{v(v+1)} \right\} \) will be simply,

\[
\frac{4}{n^2(n-1)}
\]

Also the fraction \( \frac{2}{3n} \) will vanish, and the series \(-\left( \frac{t}{4} + \frac{t^3}{4^3} + \frac{t^5}{4^5} + \&c. \right) \) will go on ad infinitum, so that upon the whole we have this rule.

To compute the value of the expression \( n(v-1) \), in which \( v \) is any positive quantity, and \( n \) a very great number, so as to admit of being reckoned greater than any assignable number.

1. Compute \( V = \frac{1}{2} \left( v + \frac{1}{v} \right) \).

2. Also compute as many terms as may be necessary of the series of quantities \( V, V^2, V^3, &c. \) from its formula.

\[
V' = \sqrt{V + \frac{1}{2}}, \quad V'' = \sqrt{V + \frac{1}{2}}, \quad V'' = \sqrt{V + \frac{1}{2}}, \quad &c.
\]
each being formed from that before it, exactly according to the same law.

3. Lastly, compute an equal number of terms of the series \( t', t'', t''', &c. \) from the formula,

\[
t' = \frac{V^2}{V + 1}, \quad t'' = \frac{V^2}{V + 1}, \quad t'' = \frac{V^2}{V + 1}, \quad &c.
\]

Then shall

\[
\frac{1}{n^2(n-1)} = \left\{ \frac{v}{(v-1)^2} \right\} + \frac{1}{12} \left\{ \frac{1}{(v-1)^2} \right\} + \frac{1}{4} \left\{ \frac{1}{v^2} \right\} + \frac{1}{4^3} \left\{ \frac{1}{v^3} \right\} + \&c.
\]

The series being supposed to proceed indefinitely.

Note. When any term of the series is found to be nearly \( \frac{1}{v} \) of the term before it, the remainder of the series may be reckoned a geometrical progression, of which the common ratio is \( \frac{1}{v} \), and therefore its sum will be nearly \( \frac{1}{v} \) of that term.

The formula gives the value of the square of the reciprocal of the quantity to be found, but hence the quantity itself may be readily obtained.

Calculation of the formula \( n(v-1) \), supposing that \( w = 10 \).

In this case

\[
\begin{align*}
V &= 5.05 \\
V' &= 1.7309457130927 \\
V'' &= 1.70310867511667 \\
V''' &= 1.041707620748 \\
V^4 &= 1.010837914520 \\

\end{align*}
\]

\[
P = \text{Sum of positive terms}, \quad .2067901234568
\]
the number $B$ is the Napierian logarithm of 10, so that
\[ e^B = 10, \quad \text{and} \quad B \times \text{com. log. } e = \text{com. log. } 10 = 1; \]
and hence \( \text{com. log. } e = \frac{1}{B} = 0.434294481803 \). By inspecting a table of logarithms, it appears that \( eB = 2.71828 \) nearly; its more accurate value will appear hereafter to be \( eB = 2.718281828459 \). Let us now denote the Napierian logarithm of any number \( x \) by enclosing the symbol for the number in a parenthesis, and putting the letter \( b \) before it thus, \( B(x) \). Then, from what has been shown in this article, we may infer, that in any system of which the basis is \( b \),
\[
\log x = \frac{n}{\frac{x}{b^x} - 1}; \quad (F)
\]
and it is to be observed, that in Napier's system \( (b) = 1 \).

From this formula, and the series which we have found for its development in the preceding article, we may find the logarithm of any number whatever. Another development of the same quantity will be given as an exemplification of the application of the fluxional calculus, which, however, does not converge so fast as that here given. The series more commonly known for the logarithm of a number, will also be investigated in the sequel.

13. We are now prepared to investigate the general expression for the ratio of the increments of logarithmic and exponential functions, and begin with \( u = \log x \). Let us suppose, that when \( x \) becomes \( x + h \), then \( u \) becomes \( u' \), hence, putting \( B \) for \( b \), \( (b) \), (that is, for the Napierian logarithm of the basis of the system), we have, by formula \((F)\),
\[
u = n \left( \frac{x}{b^x} - 1 \right); \quad (Bx)^n = \left( x + h \right)^x
\]
and therefore,
\[
u' = \frac{n}{x} \left( \frac{x}{b^x} - 1 \right); \quad (Bx)^n = \left( x + h \right)^x
\]
and taking the difference, and dividing by \( h \),
\[
\frac{u'(x + h)^x - u}{h} = n \left( \frac{(x + h)^x - x^x}{x^{x-1}} \right).
\]

But, by formula \((B)\), \( (Art. 7.) \) the second member of this equation is equal to
\[
\frac{1}{x^{x-1}} \left( \frac{x + h}{x} \right)^{x-1} \left( 1 + \frac{h}{x^{x-1}} \right) \quad (c' \text{ being a quantity between } 0 \& 1). \]

Therefore,
\[
\frac{u'(x + h)^x - u}{h} = n \left( \frac{(x + h)^x - x^x}{x^{x-1}} \right).
\]

As we are at liberty to suppose \( n \) as great as we please, and as \( x \) and \( x' \) are always of an intermediate magnitude between 0 and 1; if we suppose \( n \) to be very great, \( \frac{x}{n} \), \( \frac{x'}{n} \), and \( \frac{1}{n} \) may be each reckoned \( = 0 \),

and then \( (x + h)^x, \left( \frac{x + h}{x} \right)^{x-1} \), and \( \left\{ \frac{x + h}{x} \right\}^{x-1} \) are each to be accounted \( = 1 \); our formula becomes now simply,
\[
\frac{u'(x - u)}{h} = n \left( \frac{x + h}{x} \right)^{x-1} \; \text{or}
\]
and hence, substituting for \( u' \) and \( u \) their values,
\[
\log (x + h) - \log x = \frac{1}{B} \frac{1}{x^{1-c} (x + h)^{x-1}}.
\]

From this formula we see, that the function which expresses the ratio of the increments of \( \log x \), and \( x \), has the general properties which we have shewn in Art. 7., to belong to the function which expresses the ratio of the increments of \( x^x \), and \( x \); but that the expression for its boundaries has a different form. If we make \( x' = 0 \), we get \( \frac{1}{B} \) for one boundary; and if we make \( x' = 1 \), we have \( \frac{1}{B(x + h)} \) for the other boundary; and between these, the value of the function expressing the ratio is always contained. Or we may indicate both boundaries at once, by this expression
\[
\frac{1}{B(x + h)} = \frac{1}{Bx + H} \quad (G')
\]

14. Next let the function be \( a^x \), where \( a \) denotes a constant; positive quantity, and \( x \) any variable quantity. When \( x \) changes to \( x + h \), then \( a^x \) changes to \( a^{x + h} = a^x \cdot a^h \), therefore \( a^{x + h} - a^x = a^x (a^h - 1) \).

We have found \( (Art. 9, \text{ and art. } 12.) \) that if \( x = b^u \), then \( u = \left( \frac{x}{b} - 1 \right) \), \( n \) being any number, and \( x \) a certain quantity between 0 and 1, and \( B = (b) \). In this formula put \( b^u \) instead of its representative \( x \), and it becomes \( u = \left( \frac{a^x - 1}{a^h - 1} \right) \). To adapt this expression to our present purpose, change \( u \) into \( h \), also \( b \) into \( a \), and \( B \) into \( A \), (that is, \( B = (b) \) into \( 1 (a) \) ) and it becomes
\[
h = \frac{n(a^x - 1)}{a^h - 1}, \quad \text{or putting for the present } A' = \Lambda a^x, \text{ we have }
\]
\[
\Lambda a = \frac{h}{a^h - 1}, \quad \text{and hence, } a^h = \left( 1 + \frac{A'h}{n} \right)^n; \quad \text{and}
\]
\[
a^{x-1} = \left( 1 + \frac{A'h}{n} \right)^{a^h - 1}.
\]

Now we have found \( (Art. 7.) \) that
\[
(x + h)^n - x^n = nx^{x-1} \left( \frac{x + h}{x} \right)^{x-1}.
\]
fundamental principles.

Therefore, putting in this expression 1 instead of \( x \), and
\[
\frac{\Delta h}{n}
\]
instead of \( h \) and \( z' \) for a certain quantity between
0 and 1, we get
\[
\left( 1 + \frac{\Delta h}{n} \right)^n - 1 = \lambda'(1 + \frac{\Delta h}{n})^{x(1-n)} h;
\]
but since \( 1 + \frac{\Delta h}{n} = a^k \), the second member of the a-

above equation is also equal to \( \frac{\Delta h}{n} a^{k'} \); therefore after

putting for \( \lambda' \) the expression it denotes, we get
\[
\frac{a^{k+1} - a^x}{h} = \frac{\Delta h}{n} a^{k+1} a^{x+k}.
\]

Now, as we have it in our power to make \( n \) as great as we
please, let us suppose it a very great number; then
\[
\frac{z}{n}
\]
may be reckoned \( = 0 \), and \( a^{k+1} = 1 \), and \( \frac{\Delta h}{n} a^{n} = 0, \)

thus we have simply \( a^{k+1} - a^x = a^{x+k} \). (I)

and as \( a^{k+1} - a^x = a^{x+k} \), we have, that follows,
\[
\frac{a^{k+1} - a^x}{h} = \frac{\Delta h}{n} a^{x+k}.
\]

(II)

\( z' \) being, as already stated, a quantity between 0 and 1.

This expression for the ratio of the increments of \( a^x \)
and \( x \) agrees in its general properties with that for the
ratio of \( a^x \) and \( x \), (art. 7.) Its boundaries found by

making \( z' = 0 \) and \( z' = 1 \) are \( a^x a' \) and \( a^x a' \); therefore, if we put \( h' \) for some quantity between 0 and \( h \), we shall have
\[
\frac{a^{x+k} - a^x}{h'} = \frac{\Delta h}{n} a^{x+k}.
\]

(III)

And as again, by equation (I) of this article, \( a^k = \)
\( 1 + \frac{\Delta h}{n} a^{k'} \), if we put \( H = \frac{\Delta h}{n} a^{k'} \), where \( H \) denotes
a quantity that vanishes when \( h' \) or \( h = 0 \), we shall also

have this formula
\[
\frac{a^{x+k} - a^x}{h} = \frac{\Delta h}{n} a^{x+k} + H.
\]

(IV)

15. We come now to the circular functions sin, \( x \),
and cos, \( x \), that is, the sine and cosine of \( x \), an arc of a
circle, the radius of which we shall assume \( = 1 \); and
we are to investigate in each case an expression for the
ratio of the increments of the function, and of the arc,
which we consider as its variable basis.

Supposing \( x \) and \( a \) to be any arcs, from the fourth
of formula (C) Arithmetic of Sines, Art. 12. we derive
the following series of equations,
\[
\text{Sin.} \ (x+a) = \sin x \sin a \cos (x+a),
\]
\[
\text{Sin.} \ (x+a) = \sin (x+2a) + \sin (x+3a),
\]
\[
\text{Sin.} \ (x+a) = \sin (x+4a) + \sin (x+5a),
\]
\[
\text{Sin.} \ (x+2a) = \sin (x+3a) + \sin (x+4a).
\]

Sin. \( a \cos (x+2n-1)a = 2 \sin a \cos (x+2n-1)a \); the number of equations
being \( n \).

By taking the sums of the corresponding members

of these equations, and rejecting the quantities found
with opposite signs, we find
\[
\sin (x+2n-1)a = \sin x = \frac{2 \sin a}{\cos (x+a) + \cos (x+3a) + \cos (x+5a) + \ldots + \cos (x+2n-1)a}.
\]

Now, if the greatest term of this series of cosines be
multiplied by the number of terms, the product will be
a quantity evidently greater than their sum; and if
the least term be multiplied by their number, the product
will be a quantity less than their sum; therefore, between the greatest and least, there must be some
quantity of an intermediate magnitude, such that if it
be multiplied by the number of terms, the product
will be exactly equal to their sum. This quantity
will have the form \( \cos (x+N \alpha) \) where \( N \) is some positive
quantity of an intermediate magnitude between the
co-efficients of \( a \) in the greatest and least terms of the
series; it must therefore be less than \( 2n \): We have now
\[
\cos (x+a) + \cos (x+3a) + \ldots + \cos (x+2n-1)a
\]
\[
= n \cos (x+N \alpha) \]; and hence
\[
\sin (x+2n \alpha) = \sin x = \cos (x+N \alpha) \]

Let us now put \( h=2 \alpha \); then \( a = \frac{h}{2n} \) and \( N \alpha = \)
\( \frac{N h}{2n} \); as \( N \) is always less than \( 2n, \frac{N h}{2n} \) will be a positive
fraction less than 1, let us denote it by \( z \), and also let us put \( z' \) or rather \( n \) instead of \( 2n \), and upon the
whole we shall have
\[
\sin (x+a) = \sin (x+z \alpha) \]
\[
= n \cos (x+N \alpha) \]
\[
\cos (x+a) + \cos (x+3a) + \cos (x+5a) + \ldots + \cos (x+2n-1) \]
\[
= 2 \sin a \cos (x+2n-1) \alpha = 2 \sin a \sin (x+2n-1) \alpha.
\]

16. By the second of formula (C) Arithmetic of Sines, Art. 12. we have the following series of equations,
\[
\cos x = \cos (x+2a) = 2 \sin a \sin (x+a),
\]
\[
\cos (x+4a) = 2 \sin a \sin (x+4a),
\]
\[
\cos (x+6a) = 2 \sin a \sin (x+6a).
\]

As the sum of this series of sines will be less than the
greatest term multiplied by the number of terms, and
greater than the least term multiplied by the same
number, it must be exactly equal to some quantity of an
intermediate magnitude multiplied by that number.
This quantity may evidently have the form
\[
\sin (x+N \alpha), \] where \( N \) denotes a positive quantity
less than \( 2n \); we have therefore
\[
\sin (x+a) + \sin (x+3a) + \ldots + \sin (x+2n-1) \alpha = n \sin (x+N \alpha).
\]

* In the series of arcs \( x+a, x+3a, x+5a, \&c. \) the cosines
of those less than \( a \) quadrant will be positive quantities; and
the cosines of those greater than \( a \) quadrant, but less than three
quadrants, will be negative. Here we reckon that to be the greatest
term which is nearest to \( +1 \); and that to be the least which is nearest to \( -1 \).
We shall now bring into one point of view the different expressions for the ratio of the corresponding increments of the five simple functions considered in this section,.

\[ \frac{x^h}{h} = x_n - x \]

\[ \frac{\log (x + h)}{h} = \frac{1}{B(x + h)} + \frac{1}{B^2} + H; \]

\[ \frac{a^h}{h} = a x^h + H; \]

\[ \frac{\sin (x + h)}{h} = \sin (x + h') - \sin x; \]

\[ \frac{\cos (x + h)}{h} = \cos (x + h') - \cos x. \]

In the function \( \log x \) the limit is \( \frac{1}{B} \), \( B \) being the Napierian logarithm of the base. In the function \( ax \) the limit is \( A \); \( A \) being the Napierian logarithm of \( a \); and, lastly, in the two functions \( x^n \) and \( x \), the limits are \( x \) and \( x \) respectively, so that each limit is a new function of \( x \), peculiar to the original function from which it is derived. We have seen, (art. 8,) that the property of the limiting ratio extends to the algebraic functions \( A x^n + B x^{n-1} + \cdots \), and \( A x^n + B x^{n-1} + \cdots \), which are composed from the simple algebraic function \( x^n \); and in the same manner it will appear that the property belongs to every expression, composed in any manner whatever, by the opera-
FLUXIONS.

To express the proposition analytically under this extended form, it will be convenient to adopt a suitable notation; therefore, like as we have denoted the size of an arc by the symbol $\sin x$, and the logarithm of $x$ by $\log x$, also by $f(x)$, so we may now denote any function whatever, of a variable quantity $x$, by the symbol $f(x)$, or $F(x)$: and here it must be observed, that the letter $f$ or $F$ is not to be considered as a co-efficient, but as a characteristic, indicating that the expression $f(x)$ is formed in a determinate manner from the variable quantity $x$, and constant quantities. And as, by substituting $x+h$ instead of $x$, in the expression $\log x$, it becomes $\log (x+h)$, so, when $x+h$ is substituted instead of $x$ in the expression $f(x)$, it becomes then $f(x+h)$.

Employing this notation, we may consider the following general analytical fact as sufficiently established.

Let $f(x)$ denote any expression or function, formed from a variable quantity $x$, and constant quantities. Suppose $x$ to be augmented by the increment $h$, so as to become $x+h$; by which the function will change its value, and become $f(x+h)$: Then, in every case,

$$f(x+h) = f(x) + \frac{p}{h} + H; \quad (M)$$

where $p$ is a new function of $x$, which is independent of $h$; and $H$ is a function of $x$ and $h$, which has the property of vanishing when $h=0$. So that $p$ is a limit to which the function which expresses the ratio continually approaches, as $h$ decreases.

19. The proposition may be put under another form. For from the formulae which express the ratio of the increments, we have also these,

$$f(x+h) = f(x) + p + H; \quad (N.)$$

From these formulae we learn, that, if in $f(x)$, any function of a variable quantity, we substitute $x+h$ instead of $x$, $h$ being some quantity independent of $x$, then $f(x+h)$, the new value of the function, is equivalent to an expression, one term of which is $f(x)$, the original function; another, $p$, is the product of the first power of $h$ by $p$, some function of $x$ which is quite independent of $h$, and derives its form from that of the original function, and is deducible from it: and the remainder of the expression, viz. $H$, is the product of $h$ by $H$, a function of $x$ and $h$, which is finite, while $h$ has a finite value, but which vanishes when $h=0$.

In the expression

$$f(x+h) = f(x) + p + H,$$

the function $p$ may be made the object of analytical investigation; but as $p$ is also the limit of the ratio

$$\frac{f(x+h) - f(x)}{h} = p + H;$$

to determine that limit, and to find the co-efficient of the simple power of $h$ in the development of $f(x+h)$, are the same analytical problem.

The property of a limit, which we have proved to belong to every variable function, affords a foundation for an analytical theory of great extent and importance. Its object is twofold:

1. To determine the limit to the ratio of the increments in any proposed function.

2. To determine, on the other hand, the function, having given the limit to the ratio of the increments.

This theory, considered under different points of view, is the method of fluxions of Newton, and the differential calculus of Leibnitz.

20. In explaining the method of fluxions, Newton, and almost all writers on the subject in this country, have employed considerations drawn from the theory of motion. According to their view of the subject, in order to represent a quantity $f(x)$ as a function of another variable quantity $x$, two points $c$ and $C$ are supposed to start at the same instant from the positions $a, A$, and to move along the lines $a, x$.

Let $c$ be supposed to move uniformly, and $a, e$, the distance it has gone in any time, is taken as a geometrical expression for $x$. The motion of the other point, $C$, is supposed to be so regulated, that $AC$, the distance it has gone in the same time, may represent the function $f(x)$: If, for example, $f(x)=x^2$; then the number which expresses the line $AC$ will always be the square of the number which expresses $a, c$.

It is easy to see that there is no function whatever of a variable quantity which may not be conceived to be generated in this manner. And it also appears that while the point $e$ that generates $x$ moves uniformly, the point $C$ that generates the function $f(x)$ will move faster or slower, according to the nature of the function, but never uniformly, except in the case when $f(x)$ has a constant ratio to $x$. In some cases it will continually increase, and in others it will decrease, or it may first increase, and then decrease, or vice versa, according to the particular nature of the function, which expresses the law of the motion.

21. Let us now enquire how these velocities, or the rates according to which the variable quantities increase and decrease, may be determined; and to fix our ideas, let us take the particular case of $f(x)=x^2$, so that the line $AC$ is always the third power of the line $ae$.

Let us suppose that in two equal succeeding portions of time, the point that generates $x$, passes over the lines $bc, cd$, which will be equal, because the motion is uniform; also, that in the same equal intervals of time, the point which generates $f(x)$ passes over the corresponding lines $BC, CD$; these will be unequal, and the latter greater than the former; because when $x$ has the successive values $1, 2, 3, 4, &c.$ which increase uniformly, the corresponding values of $f(x)$ are $1, 8, 27, 64, &c.$ which increase faster and faster. Let $u$ and $V$ denote the very velocities with which the generating points arrive at $e$ and $C$, and $s$ the space which would be described by the point $C$ if it were to move with the velocity $V$, constant, during one of the equal intervals of time in which it actually describes the spaces $BC, CD$, with a variable velocity; then, because in the same time, the point $c$ has described the equal spaces $bc, cd$ with the constant velocity $v$, we have, by the principles of motion, $\frac{u}{v} = \frac{b}{c} = \frac{s}{cd}$. Now, the
line BC being described with a variable velocity, that is always less than \( V \), and CD with a variable velocity that is always greater than \( V \); the line BC will be less than \( s \), and the line CD greater than \( s \), and consequently \( \frac{BC}{b'c'} \) will be less than \( \frac{s}{b'c'} \), and \( \frac{CD}{c'd'} \) will be greater than \( \frac{s}{c'd'} \); therefore \( \frac{V}{v} \geq \frac{BC}{b'c'} \), and \( \frac{V}{v} \geq \frac{CD}{c'd'} \). So that, in every case the ratio of the velocities of the generating points at any contemporaneous position, is always between the ratio of any finite increments generated in an interval of time that ended when they arrived at that position, and the ratio of any finite increments generated in an interval of time that began when they left it; that is, the ratio of the velocities is greater than the one, but less than the other of these ratios; provided that while the increments are described, the velocities are always increasing, or always decreasing.

We have observed that the succeeding increments BC, CD generated in the same time must be unequal, because of the acceleration or retardation of the motion; the less, however, these increments are taken, the less will be the effect of the acceleration or retardation, and the more nearly will the ratio of the lines BC, CD approach to that of equality: Hence it follows, that, by continually diminishing the increments, the two ratios \( \frac{BC}{b'c'} \) and \( \frac{CD}{c'd'} \) may be as nearly equal as we please; and as the ratio \( \frac{V}{v} \) is always between them, it must be a limit to both. Therefore, the ratio of the velocities of the generating points at any instant, is the limit of the ratio of the increments generated in any interval of time immediately preceding or succeeding that instant.

22. It appears, therefore, that the Newtonian mode of conceiving a variable quantity, and its function to change their value, gives rise to, and brings under contemplation, another class of quantities, namely, the velocities of the motions of the generating points; or the rates according to which the variable quantities increase or decrease. The variable quantities themselves have been called "Flowing Quantities," also "Fluents"; and the velocities of the points which generate the variable quantities, have been called their "Fluxions.

Although it must be allowed that a correct notion may be formed of the fluxion of a variable quantity from this definition, yet it has been rejected by all the foreign writers on the subject, and by some of the English: For it has been justly observed, that to introduce motion into a calculus which treats of algebraic quantities, is to bring in an idea quite foreign to the subject; and, moreover, according to this view of the matter, all quantities ought in strictness to be represented by lines; a mode of reasoning which, although accurate, is nevertheless inconvenient.

We have seen (Article 21.) that the determination of the velocities with which variable quantities are generated, leads us naturally to the limiting ratio of their corresponding increments, so that the fact, that every variable quantity has something related to it, which may be made the subject of mathematical investigation, namely, the velocity with which it increases, resolves itself ultimately into this other fact, that there is a certain determinable limit to the ratio of the corresponding increments of a function, and the variable quantity from which it is formed.

We have found that the existence of this ratio, and the manner of finding it, rests upon principles purely analytical. It seems, therefore, to have been entirely without necessity, that motion has ever been employed in explaining the theory of fluxions; and although we shall retain the terms "Fluxion and Fluent," because no good purpose could be answered by exchanging them for others, we shall not hesitate to reject the cumbersome apparatus of reasoning, as well as the incommodious notation hitherto employed in this country, and adopt the more legitimate theory and convenient notation of the foreign writers.

Definitions and Notation.

23. Resuming the formula

\[
\frac{f(x+h) - f(x)}{h} = p + H,
\]

in which \( f(x) \) denotes any function of a variable quantity \( x \); \( h \) the increment of \( x \); \( f(x+h) \) the new value of the function when \( x \) changes to \( x+h \); \( p \) that part of the general expression for the ratio which is independent of \( h \), and which is always a new function of \( x \), deducible from the original function \( f(x) \); and \( H \) the other part of the expression which vanishes when \( h = 0 \); and contemplating the analytical fact, that supposing \( h \) to decrease, the ratio \( \frac{f(x+h) - f(x)}{h} \) approaches continually to the ratio of \( p \) to 1; we shall call this last the Fluxional Ratio. According to this definition, as in the function \( x^n \), we have found that \( \frac{(x+h)^n - x^n}{h} = n x^{n-1} + H \) (art. 7), therefore

\[
\text{Fluxion of } (x^n) = \text{Fluxion of } x : n x^{n-1} : 1;
\]

and in general

\[
\text{Fluxion of } f(x) = \text{Fluxion of } x : p : 1;
\]

from which it follows that

\[
\text{Fluxion of } (x^n) = n x^{n-1} \times (\text{Fluxion of } x);
\]

and in general, fluxion of \( \left\{ f(x) \right\} = p \times \text{fluxion of } x \).

By this definition, the quantity \( p \) enters always as a co-efficient into the expression for the fluxion of the function; we shall therefore call it the Fluxional Coefficient.

From this view of the subject, the fluxion of a function is not an absolute, but a relative quantity, which depends upon, and is co-existent with another quantity of the same kind, namely, the fluxion of the variable quantity \( x \), from which the function is formed. We may therefore define the fluxions of a variable quantity, and any function of that quantity to be any indefinite quantities which have to each other the limiting ratio of their simultaneous increments.

The different views which Newton and Leibnitz took of this theory, and the claim of each to the invention, produced at first two distinct modes of notation, an in-
The theory of fluxions resolves itself into two principal branches. Having given the relation of the fluxions of two variable quantities, it is to be found by the English writers, the French and the English writers, the French and the latter.

The fluxion of the power of a variable quantity, has been called in France, the fluxion of the variable quantity itself.

In the Direct Method of Fluxions, we proceed to treat of these in detail.

SECTION II.

OF THE DIRECT METHOD OF FLUXIONS.
substituting \( x + h \) for \( x \), the function becomes \( (x + h)^{n} \).

Now, \((x + h)^{n} = x^{n} + n x^{n-1}h + H h \). (Art. 19.)

Here, \( n x^{n-1}h \) is the only part of this expression that consists of the first power of \( h \) multiplied by a coefficient which is independent of \( h \); therefore, in this case, \( p \), the fluxional coefficient, is \( n x^{n-1} \); and changing \( h \) into \( dx \), we have

\[
d u = n x^{n-1} dx.
\]

Hence this rule,

\[
(A)
\]

The fluxion of \( x^{n} \), any constant power of a variable quantity, is the continual product of the exponent; a power of the same quantity, whose index is one less than the index of the power proposed; and the fluxion of the quantity.

II. Let \( x = \log x \). Then,

\[
\log (x + h) = \log x + \frac{h}{x} + H h; \quad \text{(Art. 19.)}
\]

Here \( b \) denotes the basis of the system, and \( l. (b) \), the Napierean logarithm of \( b \). Therefore, in this case, the fluxional co-efficient is \( \frac{1}{x l. (b)} \), and

\[
d u = \frac{d x}{x l. (b)}.
\]

Hence this rule,

\[
(B)
\]

The fluxion of the logarithm of a variable number \( x \) is a fraction whose numerator is the fluxion of the number, and denominator is the product of the number by the Napierean logarithm of the basis of the system.

Note.—In the Napierean system, \( l. (b) = 1 \). In the common system we have found, \( l. (b) = \frac{1}{b-1} \).

III. Let the function be \( u = x^{n} \), a being constant, and \( x \) variable. We have found that

\[
\frac{d x}{x} = a^{x} l. (a), \quad \text{and} \quad \frac{d u}{x} = a^{x} l. (a).
\]

This expression gives the following rule:

\[
(C)
\]

The fluxion of a variable power of a constant quantity is the continual product of that power; the Napierian logarithm of the constant quantity; and the fluxion of the variable exponent.

IV. Next, let \( x = \sin x \) or \( \cos x \); then we have (Art. 19.)

\[
\begin{align*}
\sin (x + h) &= \sin x + \cos x \cdot H h \quad \text{and} \\
\cos (x + h) &= \cos x - \sin x \cdot H h;
\end{align*}
\]

In the first of these expressions, the fluxional co-efficient is \( \cos x \), and in the second it is \( -\sin x \); therefore,

\[
d u = d (\sin x) = d x \cos x; \quad \text{and} \quad d u = d (\cos x) = -d x \sin x.
\]

In determining the limit of the ratio of the increments of the sine or cosine of an arc to that of the arc itself, (article 17.), we have considered the arc as the variable basis, and the sine and cosine as its function. But it is easy to see from the expression for the ratios, that the limit will be the very same, if on the contrary we consider the sine or the cosine as the variable basis, and the arc as the function. Since, then, upon the first hypothesis, we have the fluxional ratios \( \frac{d (\sin x)}{d x} = \cos x \), and \( \frac{d (\cos x)}{d x} = -\sin x \); we have, upon the other hypothesis, the fluxional ratios,

\[
\frac{d (\sin x)}{d x} = -\sin x, \quad \frac{d (\cos x)}{d x} = \cos x.
\]

Or, putting \( u \) instead of \( x \), reserving \( x \) to denote the variable basis of the function,

\[
\frac{d u}{d (\sin u)} = -\sin u, \quad \frac{d u}{d (\cos u)} = \cos u.
\]

Now put \( \sin u = x \), then \( \cos u = \sqrt{1 - x^{2}} \), and from the first of these formulae we have,

\[
\frac{d u}{d x} = \sqrt{1 - x^{2}}, \quad \text{and} \quad \frac{d u}{d (\cos u)} = \sqrt{1 - x^{2}}.
\]

Next, let \( \cos u = x \), then \( \sin u = \sqrt{1 - x^{2}} \), and from the second formula we have,

\[
\frac{d u}{d x} = \sqrt{1 - x^{2}}, \quad \text{and} \quad \frac{d u}{d (\sin u)} = \sqrt{1 - x^{2}}.
\]

Hence the following rule, which applies alike, whether the sine and cosine be considered as functions of the arc or the arc be considered as a function of the sine or of the cosine.

\[
(D)
\]

The fluxion of the sine is equal to the fluxion of the arc multiplied by the cosine: and the fluxion of the arc is equal to the fluxion of the sine divided by the cosine.

The fluxion of the cosine is equal to the fluxion of the arc multiplied by the sine, and the negative sign prefixed to the result; and the fluxion of the arc is equal to the fluxion of the cosine (with the sign —) divided by the sine.

27. Let \( u \) and \( v \) be any functions of \( x \), and let it be proposed to find the fluxion of \( y = a + bv - cu \), where \( a, b, c \), denote constant quantities.

Let \( p \) and \( p' \) be the fluxional coefficients of \( u \) and \( v \) respectively. Then, (Art. 19.) when \( x \) becomes \( x + h \), \( v \) becomes \( v + ph + H h \), and \( u \) becomes \( u + p'h + H'h \).

Where \( H \) and \( H' \) denote quantities composed of \( x \) and \( h \), which have the property of vanishing when \( h = 0 \). Let us suppose that when \( x \) becomes \( x + h \), then \( y \) becomes \( y' \), then

\[
y' = a + b(v + ph + H h) - c(u + p'h + H'h);
\]

that is \( y' = y + (bp' - cp')h + H'H'h \), where \( H'H' \) is put for \( H' - H \).

Hence it appears, that the fluxional co-efficient of \( y' \) is \( bp' - cp' \), and therefore \( dy' = (bp' - cp')dx = bpdx - cp'dx \). But \( p \) and \( p' \) being the fluxional co-efficients of \( v \) and \( u \),

\[
d p = u dx = ph dx + H h; \quad \text{and} \quad p' dx = du = ph dx + H h.
\]

Hence this rule,

\[
(E)
\]

The fluxion of a function which consists of several terms, is the sum of the fluxions of the terms each retaining the sign and co-efficient of the term.

Note.—The fluxion of a constant term is to be reckoned \( = 0 \).

28. It may perhaps appear almost self-evident, that if two functions of the same variable quantity be equal, their fluxions will also be equal. We shall, however, demonstrate this proposition, because of its great importance in the theory.

Let the two functions be \( f(x) \) and \( F(x) \), which we suppose are always equal, although they may be of a different form: For example, \( f(x) = \frac{1}{2} \), and

\[
F(x) = \left\{ \begin{array}{ll}
\frac{1}{2} & \text{if } 0 < x < 1 \\
\frac{1}{2} + x & \text{if } x > 1
\end{array} \right.
\]
two expressions which form
the members of the identical equation \( \frac{2}{1 - x} = 1 \) and 

\[ f(x) + p h + H h = F(x) + p h' + H h' \] (art. 19.) and as the functions are supposed equal for all values of \( x \), we must have 

\[ (f(x) + p h + H h = F(x) + p h' + H h'). \]

And since \( f(x) = F(x) \), therefore, 

\[ p h + H h = p h' + H h. \]

Now, \( p \) and \( p' \) are entirely independent of \( h, H \) and \( H' \), vanish when \( h = 0 \); therefore, in order that \( p h + H h = p h' + H h' \) may be universally equal, we must have 

\[ p = p', \quad H = H': \quad \text{Hence } pd x = p' d x, \text{ that is,} \]

\[ d\left\{f(x)\right\} = d\left\{F(x)\right\}. \]

The converse of this proposition does not hold true; for \( dx \) may be the fluxion of \( x \), or the fluxion of \( x + c \), \( c \) being any constant quantity. So that in general, from the equation \( dv = du \), we may infer that 

\[ v = u + c. \]

29. Let it be required to find the fluxion of the product of \( v \) and \( u \); two functions of \( x \).

Let \( v = u \). Put \( p \) and \( p' \) for the fluxional co-efficients of \( v \) and \( u \); then when \( x \) becomes \( x + h \), 

\[ v \text{ becomes } v + ph + H h, \]

\[ u \text{ becomes } u + ph' + H'h, \]

and \( y \) becomes \( y' \); therefore 

\[ y' = \left(v + ph + H h\right)\left(u + ph' + H'h\right), \]

that is, 

\[ y' = \left\{v + \left(p + ph + H h'\right)\right\} + \left\{u + \left(p + ph' + H'h\right)\right\}. \]

and putting \( y \) for \( v u \); and \( H'h \), generally, for the amount of the terms that contain one or other of the three quantities \( H, H', h \), we have 

\[ y' = y + \left(p + ph + H h'\right). \]

Hence it appears that the fluxional co-efficient of \( y \) is 

\[ p' + ph + H'h, \]

and therefore 

\[ dy = \left(p' + ph + H'h\right)dx + \left(p + ph + H h'\right)du. \]

But \( pdx = du \), and 

\[ dx = 0. \]

Therefore, 

\[ dy = v du + u dv. \]

Hence this rule, 

\[ \text{(F)} \]

To find the fluxion of the product of two functions of the same variable quantity: Multiply each function by the fluxion of the other, and add together the products.

If we divide the two sides of the equation \( d(uv) = vdu + udv \) by \( uv \), we have 

\[ \frac{d(uv)}{uv} = \frac{v du + udv}{uv} = \frac{du}{u} + \frac{dv}{v}, \]

an expression from which we may readily find the fluxion of the product of any number of factors whatever. For, let us suppose that 

\[ u = x, s, t, \]

then 

\[ \frac{du}{u} = \frac{ds}{s} + \frac{dt}{t}, \]

and therefore, 

\[ d(stv) = ds + dt + du + dv. \]

In the same manner it may be shewn, that whatever be the number of factors, we have always 

\[ \frac{ds}{s} + \frac{dt}{t} + \frac{du}{u} + \frac{dv}{v}, \]

and hence the fluxion of the product \( stuv \ldots \&c. \) is 

\[ s t u v \ldots \&c. \times \left\{\frac{ds}{s} + \frac{dt}{t} + \frac{du}{u} + \frac{dv}{v} + \&c.\right\}. \]

If now each term be actually multiplied by the product \( stuv \ldots \&c. \) the denominator will be taken away, and the result will give us this rule:

\[ (G) \]

To find the fluxion of the product of any number of functions of a variable quantity \( x \): Multiply the fluxion of each factor by the product of all the other factors, and the sum of all these results will be the fluxion required.

30. Next, let it be required to find the fluxion of the fraction \( y = \frac{v}{u} \). Because \( v = uy \), by rule (F), 

\[ dy = y dv + u dy; \quad \text{put } \frac{v}{u} \text{ instead of } y \text{ in the second member, and we have } \frac{v}{u} = \frac{udv - vdu}{u^2} \text{ and hence} \]

\[ dy = \frac{udv - vdu}{u^2}. \]

Hence the following rule,

\[ (H) \]

To find the fluxion of a fraction, multiply the fluxion of the numerator by the denominator, and the fluxion of the denominator by the numerator; subtract the latter product from the former, and divide the remainder by the square of the denominator.

31. Let \( u \) be a function of a variable quantity \( x \), and again let \( y \) be some function of \( u \). It is required to investigate a general rule for finding the fluxion of \( y \) relatively to \( x \).

Let \( p \) be the fluxional co-efficient of \( u \) relatively to \( x \); then when \( x \) becomes \( x + h \), \( u \) becomes \( u + ph + H h \), \( u \) becomes \( u + ph' + H'h \), \( u \) becomes \( u + ph + H'h \), \( u \) becomes \( u + ph' + H'h \), and \( y \) becomes \( y' \); therefore 

\[ y' = \left(v + ph + H h\right)\left(u + ph' + H'h\right), \]

that is, 

\[ y' = \left\{v + \left(p + ph + H h'\right)\right\} + \left\{u + \left(p + ph' + H'h\right)\right\}. \]

and putting \( y \) for \( v u \); and \( H'h \), generally, for the amount of the terms that contain one or other of the three quantities \( H, H', h \), we have 

\[ y' = y + \left(p + ph + H'h\right). \]

Hence it appears that the fluxional co-efficient of \( y \) is 

\[ p' + ph + H'h, \]

and therefore 

\[ dy = \left(p' + ph + H'h\right)dx + \left(p + ph + H'h\right)du. \]

But when \( h = 0 \), then \( k = 0 \); and consequently \( K = 0 \), we may put \( H'h \) for the last term of this expression, \( \left(H'h\right)^{\text{being a quantity which vanishes when }} \]

\( h = 0 \), and then it will appear that when \( x \) increases to \( x + h \), \( y \) increases as a function of \( x \), increases to 

\[ y + p'p h + H'h. \]

Therefore, (art. 25.), \( p'p \) is the fluxional co-efficient of \( y \) relatively to \( x \), and 

\[ dy = p'pd x; \quad \text{but } p' \text{ being the fluxional co-efficient of } u \text{ relatively to } x, \text{ we have } \]

\[ dy = p'pd x. \]

Now this last expression is also the fluxion of \( y \) taken relatively to \( u \) independently of \( x \). Hence we have this rule

\[ (I) \]

To find the fluxion of \( y \), a function of \( u \), which is itself a function of a variable quantity \( x \); find the fluxion of \( y \) considered as a function of \( u \), without any regard to \( x \): The result will have the form \( pdx \), next find the fluxion of \( u \) considered as a function of \( x \), and substitute it in \( pdx \) and the result will be the fluxion of \( y \) relatively to \( x \).

52. We shall now give some examples of the application of these rules.

Example 1. Let \( u = x^3 \), or, as it may be otherwise expressed, \( u = x^3 \). By rule (A), 

\[ du = 3x^2 \frac{dx}{2}. \]

or, \( du = 3x \frac{dx}{2} \).

Ex. 2. \( u = \frac{1}{\sqrt{x}} \); that is, \( u = x^{-\frac{1}{2}} \). In this case,
Direct Method.

by rule (A) \( d u = -\frac{1}{3} x^{-1} d x = -\frac{1}{3} x^{-\frac{1}{2}} d x \)

Ex. 3. Let \( u = a + b x \sqrt{c - x} \). Rule (E) applies to this example; and as the term \( a \) is constant, we have

\( d u = b d (x^{\frac{1}{2}}) - c d (x^{-\frac{1}{2}}) \), now, by rule (A),

\( d (x^{\frac{1}{2}}) = \frac{1}{2} x^{-\frac{1}{2}} d x \)

and \( d (x^{-\frac{1}{2}}) = -x^{-\frac{1}{2}} d x = -\frac{1}{2} x^{-\frac{1}{2}} d x \); therefore,

\( d u = \frac{b}{2} x^{-\frac{1}{2}} d x - \frac{c}{2} x^{-\frac{1}{2}} d x \)

Ex. 4. Let \( u = \frac{x^3}{x^2 - 1} \). In this case, we apply rule (H), and as \( d (x^3) = 3 x^2 d x \), and \( d (1-x) = -d x \), we have

\( d u = \frac{3 x^2 d x - (1-x) d x}{x^2 - 1} \)

Ex. 5. Let \( y = (a + b x)^n \). Put \( a + b x = u \), then \( y = u^n \). This example belongs to rule (I), and proceeding as there directed, we have, by rule (A),

\( d y = n u^{n-1} d u \),

and from the equation \( u = a + b x \), by rules (B) and (E),

\( d u = b d x + c d x \). Therefore,

\( d u = \frac{b d x + c d x}{a} \)

Ex. 6. Let \( y = x (a^x + x^a) \). Put \( a^x + x^a = u \), and we have \( y = x u \). Therefore, by rule (G),

\( d y = u d x + x d u \).

Ex. 7. Let \( y = x (a^x + x^a) \sqrt{a^x - x} \). Put \( v = a^x + x^a \), and we have \( y = x v \). Therefore, by rule (G),

\( d y = v d x + x d v \).

Ex. 8. Let \( y = (x^3 + b)^3 + 2 \sqrt{(a^3 - x^3)} \times (x-b) \).

In the first place,

\( d \left\{ (x^3 + b)^3 \right\} = 2 (x^3 + b) d (x^3 + b) \)

Again, \( d \left\{ 2 \sqrt{(a^3 - x^3)} \times (x-b) \right\} \)

\( 2 \sqrt{(a^3 - x^3)} d (x-b) + (x-b) d \left\{ 2 \sqrt{(a^3 - x^3)} \right\} \)

But \( d (x-b) = d x \), and \( d \left\{ 2 \sqrt{(a^3 - x^3)} \right\} = -2 x d x \)

therefore, upon the whole,

\( d y = 6 a x^3 (x^3 + b) d x + \frac{2a^3 - 4 x^3 + 2 b x}{\sqrt{(a^3 - x^3)}} d x \)

33. We shall next give examples of logarithmic functions, putting \( \log a \) for the Napierian log of any function \( a \).

Ex. 1. Let \( u = 1 \left( \frac{x}{\sqrt{(a^3 - x^3)}} \right) \).

Put \( \frac{x}{\sqrt{(a^3 - x^3)}} = z \),

then by rule (B), \( d u = \frac{dz}{z^2} \). But by the rule for the

fraction of a fraction,

\( d z = d \left( \frac{x}{\sqrt{(a^3 - x^3)}} \right) = \frac{a^3 dx}{a^3 x^2} \)

Therefore, \( d u = \frac{a^3 dx}{a^3 x^2} \).

Ex. 2. Let \( u = \frac{1}{\sqrt{1 + x^2}} + \frac{1}{\sqrt{1 - x^2}} \).

Hence, \( d y = \frac{dx}{y^2} \), and \( d z \).

Ex. 3. Let \( u = \frac{1}{\sqrt{1 + x^2}} - \frac{1}{\sqrt{1 - x^2}} \).

Hence, \( d y = \frac{dx}{y^2} \), and \( d z \).

Ex. 4. Let \( u = \frac{1}{\sqrt{1 + x^2}} \).

As an example of an exponential quantity, let

\( y = e^x \); supposing \( y \) and \( z \) to be any functions of a variable quantity \( x \); then log. \( u = z \log y \).

Therefore, (Article 28.) \( d y = \frac{d z}{z} \).

by rules (B) and (E): Therefore, substituting \( y^2 \) for \( u \), we have

\( d y = \frac{d z}{z} \frac{y}{y} \).

34. Examples in circular functions.

Ex. 1. Let \( u = \tan x \).

Because \( \tan x = \frac{\sin x}{\cos x} \), therefore,

\( d u = d \left( \frac{\sin x}{\cos x} \right) = \cos x d (\sin x) - \sin x d (\cos x) \).

But \( d (\sin x) = \cos x \), and \( d (\cos x) = -\sin x \).

rule (D): therefore \( d u = d x \cos x \cos x + \sin x \cos x \).

In the three following examples, we shall, for the sake of brevity, merely state the results.

Ex. 2. \( u = \sec x \).

Ex. 3. \( u = \cot x \).

Ex. 4. \( u = \cosec x \).

35. In the above examples, the tangent, secant, &c. are considered as functions of the arc: but we may reverse the hypothesis, and consider the arc as a function of the tangent, or secant, &c.

Ex. 1. Let it be required to find the fluxion of an arc
considered as a function of its tangent. Put \( x \) for the tangent, and \( u \) for the arc. Then we may consider \( u \)
as a function of \( \sin u \); and again \( \sin u \) and \( \cos u \) as functions of \( x \). Now, by Rule (D), supposing \( u \) a function of \( x \), we have

\[
d u = \frac{d (\sin u)}{\cos u}
\]

(1).

And since by the Arithmetica of Sines, \( \sin u = x \cos u \), therefore considering \( \sin u \) a function of \( x \), we have, by rule (F)

\[
d (\sin u) = dx \cos u - x \cos u (\cos u) \]

(2).

But \( \cos u = \sin^2 u = 1 \); therefore, by rule (A), \( \cos u \) \( dx \cos u + \sin u \) \( \cos u d (\sin u) = 0 \), and \( d (\cos u) \)

\[
= -x \sin u d (\sin u) = -x d (\sin u) \; ; \text{ hence, from equation (2) we have,}
\]

\[
d (\sin u) = dx \cos u - x \cos u \; (\sin u) \]

(3).

From equations (1) and (3), we have, by rule (1)

\[
d u = \frac{dx}{1 + x^2}
\]

And since \( 1 + x^2 = \sec^2 u = \frac{1}{\cos^2 u} \), we have also

\[
d u = \cos u d x
\]

Ex. 2. If we supposed \( u \) to be such a function of \( x \) that \( \sec u = x \), then, \( \cos u = \frac{1}{x} \). Now regarding \( u \) as a function of \( \cos u \), we have, by rule (D)

\[
d u = \frac{d (\cos u)}{\sin u}
\]

and again considering \( \cos u \) as a function of \( x \), we have \( d (\cos u) = \frac{d}{\cos u} \). Now regarding \( u \) as a function of \( x \), we have

\[
d u = \frac{dx}{x^2 \sin u} = \frac{dx}{x^2 \sin u} = \frac{dx}{x^2 \sin u}
\]

(4).

Hence putting \( \tan u \) for \( \frac{x}{\cos u} \), we have also

\[
d u = \frac{dx}{\sec u \tan u} = \frac{dx}{x \sqrt{(x^2 - 1)}}
\]

Ex. 3. Let \( \cot u = x \); then, \( \tan u = \frac{1}{x} \). Now we have found that \( du = \frac{dx}{\tan u} \cos^2 u \) (Example 1); but

\[
d (\tan u) = \frac{dx}{x^2} \; ; \text{ therefore, } du = \frac{dx}{x^2 \cos u} \; , \text{ or}
\]

\[
since u = \cos u \sin u \]

\[
d u = \frac{dx}{x^2 \sin u} = \frac{dx}{x^2 \sin u}
\]

(5).

Ex. 4. If \( \csc u = x \); then, from the formula,

\[
d u = \frac{1}{\csc u}
\]

and \( u = \frac{1}{x} \), we easily find

\[
d u = \frac{dx}{\csc u \cosec u} = \frac{dx}{x \sqrt{(x^2 - 1)}}
\]

Some Applications of the Theory.

36. Before we proceed farther in the explication of the theory of fluxions, we shall give a few examples of its application to the investigation of analytical and trigonometrical formulæ; employing the principle demonstrated in Art. 28, namely, that if two functions of a variable quantity be universally equal to one another, their fluxional coefficients will also be equal.

By algebraic division,

\[
\frac{1}{1-x} = 1 + x + x^2 + x^3 \ldots + x^{n-1} + \frac{x^n}{1-x}
\]

and therefore,

\[
x (1-x^n) = x + x^2 + x^3 + x^4 \ldots + x^n
\]

(6),

where \( n \) denotes the number of terms of the series. As the members of this equation are equal functions of the same variable quantity \( x \), their fluxions must be equal. Now the fluxion of the first member is by rules (A) and (H)

\[
(1-x) \left\{ 1-(n+1)x^n + n x^{n+1} \right\} \frac{d x}{1-x^n}
\]

(7).

And the fluxion of the second member is

\[
d x + 2 x dx + 3 x^2 dx + \ldots + n x^{n-1} dx
\]

(8).

Hence, putting these expressions equal to one another; also, dividing both by \( dx \), and multiplying by \( x \), we get

\[
x \left\{ 1-(n+1)x^n + n x^{n+1} \right\} \frac{d x}{1-x^n}
\]

(9)

This formula may be easily verified by multiplying the second member of the equation by the denominator of the first.

Let us now, in order to abridge, put

\[
X' = \frac{1-(n+1)x^n + n x^{n+1}}{(1-x^n)^2}
\]

Then, by formula (b),

\[
X' = x + 2 x^2 + 3 x^3 + 4 x^4 \ldots + n x^n
\]

(10),

then, taking the fluxion of each side as before, and denoting briefly \( d (X') \) by \( X'' dx \), where \( X'' \) is a function of \( x \), which may be found by rules (F), (H), and (1), we have

\[
x'' dx = d x + 2 x dx + 3 x^2 dx + \ldots + n x^{n-1} dx
\]

(11)

and, dividing by \( dx \), and multiplying by \( x \), we find

\[
x'' = x + 2 x^2 + 3 x^3 + 4 x^4 \ldots + n x^n
\]

(12).

From the process by which formulæ (b) and (c) have been deduced from formulæ (a), it appears that if

we put \( \frac{1-x^n}{(1-x)^2} = X \), and compute the series of functions

\[
X', X'', X''', \text{ &c. from the fluxional formulæ}
\]

\[
d (x X) = X', \quad (x X') = X'', \quad (x X''') = X''' \text{ &c.}
\]

then we shall have

\[
x = 1 + x + x^2 + x^3 \ldots + x^n
\]

\[
x = 1 + x + x^2 + x^3 \ldots + n x^n
\]

\[
x = 1 + x + x^2 + x^3 \ldots + n x^n
\]

(1)

\&c. &c.

where \( n \) may be any whole number whatever, and \( x \) any quantity greater or less than unity. In the particular case of \( x = 1 \), the formulæ are not immediately applicable, because then the numerator and denominator of the expressions \( X, X', X'' \), &c. vanish at the same time. We shall shew, farther on, how quantities having this property are to be valued.

When \( x \) is a proper fraction, and \( n \) the number of terms infinite, the function \( X \) becomes simply \( \frac{1}{1-x} \). In this case,
FLUXIONS.

4.07

Direct Method.

Let 

\[ X' = \frac{1}{(1-x)^2}, \quad X'' = \frac{1}{(1-x)^3}, \quad X''' = \frac{1}{(1-x)^4}, \quad \text{etc.} \]

Therefore,

\[ \frac{1}{1-x} = \frac{1}{x^2} + \frac{2}{x^3} + \frac{3}{x^4} + \frac{4}{x^5} + \text{etc.} \]

\[ \frac{(1+x)}{1-x} = \frac{1}{x} + \frac{2}{1+x} + \frac{3}{1+x^2} + \frac{4}{1+x^3} + \text{etc.} \]

\[ \frac{(1-x^2)}{(1-x)^2} = \frac{1}{x} + \frac{2}{1+x} + \frac{3}{1+x^2} + \frac{4}{1+x^3} + \text{etc.} \]

By the principle employed in this article, we may discover as many series, finite or infinite, as we please, that may be summed.

37. As an example of another mode of investigating series that may be summed, let us assume the series of identical equations.

\[ 1-x^2 = (1+x)(1-x), \]
\[ 1-x^3 = (1+x)(1-x^2), \]
\[ 1-x^4 = (1+x)(1-x^3), \]
\[ \ldots \]
\[ 1-x^n = (1+x)(1-x^{n-1}). \]

By taking the products of the two sides, and leaving out the factors common to both, we obtain

\[ 1-x^n = (1-x)(1+x)(1-x^2)(1-x^4) \ldots (1+x^n). \]

Now it has been shewn, (Art. 29.) that supposing \( r, s, t, u, \ldots \) to be any functions of \( x \), if \( y = rstu, \ldots \) then

\[ \frac{dy}{y} = \frac{dr}{r} + \frac{ds}{s} + \frac{du}{u} + \ldots \]

Therefore, assuming that

\[ y = 1-x^n, \quad r = 1-x, \quad s = 1+x, \quad t = 1+x^2, \quad u = 1+x^3, \ldots \]

and taking the fluxions, we have

\[ \frac{2n x^{n-1} dx}{1-x^n} = \left\{ \frac{-dx}{1-x} + \frac{dx}{1+x} + \frac{2x dx}{1+x^2} + \frac{4x^2 dx}{1+x^3} + \ldots \right\} + \frac{n x^n dx}{1-x^n} ; \]

and hence, by dividing all the terms by \( dx \), and multiplying by \( x \), and transposing the term \( \frac{x}{1-x} \) we find

\[ \frac{x}{1-x} = \frac{2n x^n dx}{1-x^n} \]

\[ = \frac{x}{1-x} + \frac{2 x^2}{1+x^2} + \frac{4 x^3}{1+x^3} + \ldots + \frac{n x^n}{1+x^n} ; \]

This elegant analytical theorem holds true, independently of any particular value of \( x \); and whatever be the number of the terms, observing that the exponents of the powers of \( x \) must be the terms of the geometrical series \( 1, 2, 4, 8, \ldots \) the common ratio of which is 2.

38. Let us next assume this other series of identical equations.

\[ x - 1 = (x^2 - 1)(x^2 + 1), \]
\[ x - 1 = (x^3 - 1)(x^3 + 1), \]
\[ x - 1 = (x^4 - 1)(x^4 + 1), \]
\[ \ldots \]
\[ x - 1 = (x^n - 1)(x^n + 1). \]

Hence, taking the products of the corresponding sides of the two series of equations, and rejecting the terms common to both, we find \( x - 1 \) expressed by the product

\[ (x^2 - 1)(x^3 + 1)(x^4 + 1) \ldots x(x^2 + 1). \]

Hence, proceeding as in last article, dividing the fluxion of each factor by the factor itself, and leaving out \( dx \), which is common to all the terms, we find

\[ \frac{1}{x - 1} = \frac{x^{n-1}}{n(x^n - 1)} + \frac{x^{n-1}}{x - 1} + \frac{x^{n-1}}{x^2 - 1} + \frac{x^{n-1}}{x^3 - 1} + \ldots \]

and by transposing and multiplying all the terms by \( x \), we find

\[ \frac{x^n}{n(x^n - 1)} = \frac{x}{x - 1} - \left( \frac{x^2}{x^2 + 1} + \frac{x^3}{x^3 + 1} + \frac{x^4}{x^4 + 1} + \ldots \right) \]

This equation holds true, whatever be the number of terms: but let us now suppose their number infinite.

then the numerator of the expression \[ \frac{x^n}{n(x^n - 1)} \]

becomes \[ \frac{x^n}{n} = \frac{x^n}{x^n - 1} \]

and the denominator is the Napierian log. of \( x \),

(Art. 12.) Hence we have

\[ \frac{1}{x} = x - 1 - \frac{1}{x} + \frac{1}{x^2} + \frac{1}{x^3} + \frac{1}{x^4} + \ldots \]

We may give this expression another form, by writing \( \frac{1}{y} \) instead of \( x \), and afterwards changing \( y \) into \( x \), and observing that \( \log \left( \frac{1}{y} \right) = -\log (x) \); we then have

\[ \frac{1}{y} = \frac{1}{x} = x - 1 - \left( \frac{1}{x} + \frac{1}{x^2} + \frac{1}{x^3} + \frac{1}{x^4} + \ldots \right) \]

By adding the corresponding sides of these two formulae, we get this third formula,

\[ \frac{1}{y} = \frac{x + 1}{x - 1} - \left( \frac{1}{x^2 + 1} + \frac{1}{x^3 + 1} + \frac{1}{x^4 + 1} + \ldots \right) \]

which is better adapted to calculation than either of the others, because it converges faster; but it does not converge so fast as that which we have in Art. 11.

By taking the fluxions of both sides of this equation, we may find the expression for the reciprocal of the square of \( l(x) \), which has been investigated by a different method in Art. 11; and repeating the process, we may obtain expressions for the reciprocal of its third and higher powers.

39. By the Arithmetic of Sines, formula (G),

\[ \sin x = \sin \frac{1}{2} x \times 2 \cos \frac{1}{2} x, \text{ and } \sin \frac{1}{2} x = \sin \frac{1}{2} x \times 2 \cos \frac{1}{2} x. \]

Therefore,
408. **FLUXIONS.**

The reader must be careful to give each of these three symbols, $du$, $d^m u$, $d^n u$, its true meaning. The first indicates that the operation of finding the fluxion of $u$ is to be performed $m$ times; the second, that the result of the first operation is to be raised to the $n$th power; the third, that the fluxion of the $n$th power of $u$ is to be taken.

---

408. **FLUXIONS.**

Of the Different Orders of Fluxions.

41. In what has been already explained, we have established the important principle in analysis, that if $u$, any expression of calculation, be regarded as formed from, and depending upon, some quantity $x$, which is susceptible of all degrees of increase or decrease; then there is a certain quantity $p$, deducible from $u$ by determining rules, which is a limit to the ratio of the corresponding increments of $u$ and $x$; and which we have called the fluxional co-efficient, originating from the function $u$.

Now, by applying the same hypothesis to $p$, that is, by comparing its increase or decrease with the corresponding increase or decrease of $x$, the function $p$ will in like manner have its fluxional coefficient $q$, and this last will have its fluxional coefficient $r$, and so on.

Hence it follows, that corresponding to $u$, any function of $x$, there is a series of fluxional coefficients $p, q, r, \&c.$ any one of which, after the first is deducible from that before it, as the first is from the original function, by the rules which have been given for finding the fluxion of a function. For example, if $u = x^n$, then by rule (A), $\frac{du}{dx} = nx^{n-1}$, therefore in this case $p = nx^{n-1}$, and since $\frac{dp}{dx} = n(n-1)x^{n-2}dx$, rule (A), therefore $q = \frac{dp}{dx} = n(n-1)x^{n-2}$.

In like manner, $\frac{dq}{dx} = n(n-1)(n-2)x^{n-3}$, and hence $r = \frac{dq}{dx} = n(n-1)(n-2)x^{n-3}$, and so on.

The relation that each of the fluxional coefficients $p, q, r, \&c.$ stands in to the original function $u$, is indicated by calling $p$ the fluxional coefficient of the first order, $q$ that of the second order, $r$ that of the third order, and so on; so that in the case of the function $u = x^n$, the fluxional coefficients of the first, second, and third order, resulting from the function, are given.

42. The process by which the fluxional coefficients $p, q, r, \&c.$ are to be determined from the function $u$, is indicated by the series of equations

$$\frac{dp}{dx} = q, \quad \frac{dq}{dx} = r,$$

In these, the conventional symbol $dx$ enters merely as a mark to indicate that $x$ is the variable basis of the function; therefore, in performing the operations, we may treat it as if it represented some constant quantity, and so we shall have

$$\frac{dq}{dx} = \frac{d(du)}{dx}.$$

and hence again,

$$\frac{d}{dx} q = \frac{d}{dx} \frac{d}{dx} u.$$

From the manner in which the series of quantities $p d x, q d x, r d x, \&c.$ are deduced from the function $u$, we may indicate their relation to it, by calling $p d x$ the first fluxion of $u$, and $q d x$ the second fluxion of $u$, and $r d x$ its third fluxion, and so on, so that the nth...
fluxion of \( u \) (denoted by \( d^2 u \)) will be the fluxional coefficient of the \( n \)th order multiplied by the \( n \)th power of \( dx \), that is by \( dx^n \); \( \frac{d u}{d x} \) and, on the contrary, like as the fluxional coefficient of the first order is \( \frac{d u}{d x} \) the fluxional coefficient of the second order will be \( \frac{d^2 u}{d x^2} \).

43. It has been proved, (art. 23.) that if \( u \) and \( v \) are two functions, which are equal for every value of \( x \), then the fluxional coefficients of the first order derived from them will be equal, that is, \( \frac{d u}{d x} = \frac{d v}{d x} \). Now, as these expressions denote other functions of \( x \), having the same property as the original functions, we must, in like manner, have
\[
\frac{d}{d x} \left( \frac{d u}{d x} \right) = \frac{d}{d x} \left( \frac{d v}{d x} \right)
\]
that is,
\[
\frac{d^2 u}{d x^2} = \frac{d^2 v}{d x^2}
\]
so that not only will the fluxional coefficients of the first order be equal, but likewise those of the second and all higher orders.

As the equations
\[
y = v, \quad \frac{d u}{d x} = \frac{d v}{d x}, \quad \frac{d^2 u}{d x^2} = \frac{d^2 v}{d x^2}
\]
may also be expressed thus,
\[
u - v = 0, \quad \frac{d(u - v)}{d x} = 0, \quad \frac{d^2(u - v)}{d x^2} = 0, \quad \&c.
\]
it appears that the same proposition may be expressed as follows: If \( X \) be a function of \( x \), that \( X = 0 \), for all values of \( x \) whatever, then shall
\[
\frac{d X}{d x} = 0, \quad \frac{d^2 X}{d x^2} = 0.
\]

44. The rules for finding the first fluxion of a function of \( x \), are equally applicable to the second and higher fluxions.

Let \( u = x^n \); then (rule A) \( \frac{d u}{d x} = n x^{n-1} dx \). By considering \( dx \) as a constant quantity, we have \( \frac{d (du)}{dx} \), that is, \( \frac{d u}{d x} \), \( n \) \( x^n \) \( d x \). By proceeding in this manner, the successive fluxions of \( u = x^n \) are
\[
\frac{d u}{d x} = n x^{n-1} dx, \quad \frac{d^2 u}{d x^2} = 2 n x^{n-2} d x, \quad \frac{d^3 u}{d x^3} = 3 n x^{n-3} d x, \quad \&c.
\]

From these expressions, it appears, that when \( n \) is a whole number, the fluxion of the \( n \)th order is a constant quantity, and therefore all the following fluxions vanish.

Let \( u = \log x \); then \( \log \) denoting the basis of the system, by rules (B) and (A), we get
\[
\frac{d u}{d x} = x \log x, \quad \frac{d^2 u}{d x^2} = \frac{2 d x}{x \log x}, \quad \frac{d^3 u}{d x^3} = \frac{2 d x}{x \log x}, \quad \&c.
\]

Let \( u = e^x \); then \( e \) being the basis of the Napierian system of logarithms; then, by rule (C),
\[
\frac{d u}{d x} = x e^x, \quad \frac{d^2 u}{d x^2} = x e^x, \quad \frac{d^3 u}{d x^3} = x e^x, \quad \&c.
\]

From these examples, it appears, that the functions
\[
y = \log x, \quad u = e^x
\]
have fluxions of all orders whatever. This will also be found to be true of the functions
\[
y = \sin x, \quad u = \cos x.
\]

Of Fluxional Equations.

45. We have hitherto supposed that the expression whose fluxional coefficient is to be determined, was an explicit function of the variable quantity \( x \), that is, a function of \( x \) of some given form. But it may be required to find the fluxional coefficient of \( y \), an implicit function of \( x \), the nature of which is expressed by an equation. For example, the relation of \( y \) to \( x \) may be expressed by the equation
\[
y = x^2 + y^2 - a^2 = 0.
\]

In this particular case, by resolving the equation, we have
\[
y = m x \pm \sqrt{a^2 + \left( m^2 - 1 \right) x^2}
\]
as \( y \) is now an explicit function of \( x \), its fluxion may be found by the rules already given. But the equation which expresses the relation of \( y \) to \( x \) may not admit of being resolved; and when this is the case, the fluxional coefficient must be determined upon principles which we are now to explain.

As we have denoted any expression of calculation composed of \( x \) and constant quantities by the symbol \( f(x) \), we may, in like manner, denote any expression of \( x, y \), and known quantities, by \( f(x, y) \).

In this way, any equation, such as \( y^2 - 2 x y + x^2 - a^2 = 0 \), expressing the relation between \( x \) and \( y \), may be briefly indicated thus, \( F(x, y) = 0 \). Now, although we should not be able to resolve the equation, we may be certain that \( y \) is expressible in some way or other by \( x \); it may therefore be assumed that \( y = X \), where \( X \) denotes some expression of calculation made up of \( x \) and known quantities. This value of \( y \) being put instead of it in the equation \( F(x, y) = 0 \), it becomes \( F(x, X) = 0 \), an equation involving only \( x \) and constant quantities: And as the equation \( F(x, y) = 0 \) holds true for every possible value of \( x \), so also must the equation \( F(x, X) = 0 \); this must therefore be an identical equation, and consequently it will have the properties which (in art. 43.) have been proved to belong to such an equation: So that putting \( u \) to denote briefly the expression \( F(x, X) \), or its equivalent \( F(x, y) \), we have \( u = 0 \), we must have also \( \frac{d u}{d x} = 0, \frac{d^2 u}{d x^2} = 0, \frac{d^3 u}{d x^3} = 0, \&c. \)

expressions which mean that if the fluxion of \( u = F(x, y) \), considering \( y \) as a function of \( x \), be found and divided by \( dx \), the result will be \( 0 \); and again, if the fluxion of this quantity be found and divided by \( dx \), this second result will be \( 0 \), and so on.

46. Let \( y \) be a function of \( x \), of such a nature that
\[
y^2 + x^2 - a^2 = 0,
\]
a being supposed a constant quantity. In this case,
\[
\frac{d u}{d x} = y^2 + x^2 - a^2,
\]
therefore, taking the fluxions and dividing by \( dx \), we get
Direct Method.

\[
\frac{du}{dx} = 2y \frac{dy}{dx} + 2x = 0;
\]

Hence,
\[
\frac{dy}{dx} = -\frac{x}{y}. \quad (2)
\]

To determine the fluxional coefficient of the second order, put \(\frac{dy}{dx} = p\); then
\[
\frac{du}{dx} = 2(y p + x).
\]

As \(p\) is a function of \(y\) and \(x\), and \(y\) is a function of \(x\), therefore \(p\) is a function of \(x\). Taking now the fluxions relatively to \(x\), and dividing by \(dx\), we have
\[
\frac{d^2u}{dx^2} = 2\left(y \frac{dp}{dx} + p \frac{dy}{dx} + 1\right) = 0;
\]
that is, because \(p = \frac{dy}{dx}\) and \(\frac{dp}{dx} = \frac{d^2y}{dx^2}\),
\[
\frac{d^2u}{dx^2} = 2\left(\frac{d^2y}{dx^2} + \frac{dy}{dx} + 1\right) = 0. \quad (3)
\]

This last equation gives us
\[
\frac{d^2y}{dx^2} = \frac{-1}{y} \left(\frac{dy}{dx} + 1\right).
\]

Or, since \(\frac{dy}{dx} = -\frac{x}{y}\),
\[
\frac{d^2y}{dx^2} = \frac{x}{y} - \frac{1}{y^2} \quad (4)
\]

To determine the fluxional coefficient of the third order, we may put \(\frac{d^2y}{dx^2} = \frac{dp}{dx} = q\), and then substituting \(p\) for \(\frac{dy}{dx}\) in equation (3) becomes
\[
\frac{d^3u}{dx^3} = 2\left(y q + p^2 + 1\right) = 0.
\]

By taking the fluxions of both sides of this equation, and considering that \(q\) and \(p\) are functions of \(x\) and \(y\), and consequently of \(x\), we shall have an equation involving, besides \(x\) and \(y\), these quantities,
\[
\frac{dq}{dx} \frac{dp}{dx} = \frac{d^3y}{dx^3}, \quad q = \frac{d^2y}{dx^2}, \quad \text{and} \quad p = \frac{dy}{dx}.
\]

The quantity \(\frac{dq}{dx} = \frac{d^2y}{dx^2}\) is that to be determined; the other quantities \(\frac{d^3y}{dx^3}\), \(\frac{dy}{dx}\), and \(\frac{d^2y}{dx^2}\) are expressed in equations (4) and (2) by means of \(x\) and \(y\): Hence the value of \(\frac{d^3y}{dx^3}\) may be found. And, by a like mode of proceeding, the fluxional coefficient of any order may be found.

This mode of determining the fluxional coefficients \(\frac{d^1y}{dx}, \frac{d^2y}{dx}, \frac{d^3y}{dx}, \ldots\) &c. is that indicated by the analysis (art. 45.) It evidently furnishes the following practical rule.

Take the fluxions of the terms of the equation, considering \(y\) as a function of \(x\), and dividing by \(dx\), the result will be a new equation, which serves to determine \(\frac{dy}{dx}\). Again, take the fluxions of the terms of this new equation, considering \(y\) and \(\frac{dy}{dx}\) as functions of \(x\), and the result will be an equation involving \(\frac{d^2y}{dx^2}\), and \(\frac{dy}{dx}\), which, combined with the former equation, serves to determine \(\frac{d^3y}{dx^3}\). A third equation may be formed from this by taking the fluxions, considering \(\frac{d^3y}{dx^3}, \frac{d^2y}{dx^2}, \frac{dy}{dx}\) and \(y\) as functions of \(x\), and this combined with the two former, gives the value of \(\frac{d^4y}{dx^4}\), and so on to any number of equations whatever.

Let the fluxional coefficients of the different orders be required, supposing \(y\) to be such a function of \(x\) that
\[
y^2 - 2mxy + x^2 - a^2 = 0 \quad (1)
\]

In this case, by taking the fluxions, we have
\[
(y - m x) \frac{dy}{dx} - (m y - x) \frac{dy}{dx} = 0,
\]
and hence
\[
\frac{dy}{dx} = \frac{m y - x}{y - m x}. \quad (2)
\]

From this expression, by again taking the fluxions, we find
\[
\frac{d^2y}{dx^2} = (1 - m^2) \frac{dy}{dx} - (1 - m^2) \frac{dy}{dx} - \frac{x}{y - m x} \quad (3)
\]

Or, substituting for \(\frac{dy}{dx}\) its value as expressed by equation (2), and reducing,
\[
\frac{d^2y}{dx^2} = (1 - m^2) \left(\frac{y^2 - 2mxy + x^2}{y - m x}\right). \quad (4)
\]
If we take the fluxions of both sides of equation (3), considering \(\frac{d^2y}{dx^2}\) and \(\frac{dy}{dx}\) as functions of \(x\), we shall have
\[
\frac{d^3y}{dx^3} = P \frac{d^2y}{dx^2} + Q \frac{dy}{dx} + R \quad (5)
\]

Where \(P, Q\) and \(R\) denote certain expressions composed of \(x\) and \(y\); by substituting for \(\frac{d^3y}{dx^3}\) and \(\frac{dy}{dx}\) their values given in equations (4) and (2), we may have
\[
\frac{d^3y}{dx^3} \text{ expressed in terms of } x \text{ and } y.
\]

47. The equations which may be deduced from any equation, such as \(y^2 - 2mxy + x^2 - a^2 = 0\), by treating it as directed in the rule of last article, are called Fluxional Equations. The equation itself is called the Primitive equation. The fluxional equation, which gives the value of \(\frac{dy}{dx}\) in terms of \(y\) and \(x\), is said to be of the First Order. That which gives the value of \(\frac{d^2y}{dx^2}\) in terms of \(\frac{dy}{dx}, y\) and \(x\), or else in terms of \(y\) and \(x\) only, is said to be of the Second Order; and so of the higher orders: Thus, from the primitive equation,
\[
y^2 - 2mxy + x^2 - a^2 = 0,
\]
we have found
\[
\frac{dy}{dx} = \frac{m y - x}{y - m x} = 0; \quad \frac{dy}{dx} = \frac{m y - x}{y - m x} = 0;
\]
for the fluxional equation of the first order, and
\[
\frac{d^2y}{dx^2} = \frac{(1 - m^2) \frac{dy}{dx} + (1 - m^2) y}{(y - m x)^2} = 0, \quad \text{also} \quad \frac{d^3y}{dx^3} = \frac{(1 - m^2) \left(\frac{y^2 - 2mxy + x^2}{y - m x}\right)}{(y - m x)^3} = 0,
\]
for the fluxional equations of the second order. The fluxional equations of all orders like the primitive are identical.

48. The equation \(y^2 - 2mxy + x^2 - a^2 = 0\) being of the...
second degree, \( y \) will have two values corresponding to any given value of \( x \), and as \( y \) enters into the expressions for the fluxional coefficients \( \frac{dy}{dx}, \frac{d^2y}{dx^2}, \&c. \), these will also have each two values. A like remark will apply to the fluxional coefficients derived from a primitive equation of any higher order; the number of values of \( y \) determining in every case that of the values of the fluxional coefficients into which it enters.

49. We have seen (art. 27.) that the constant quantities which enter into a function of a variable quantity in certain cases disappear from their fluxions. The same remark applies also to fluxional equations. For example, if \( y^2 = ax + b \), the fluxion \( 2y \frac{dy}{dx} \) belongs to every particular equation which can be formed from the equation \( y^2 = ax + b \), by giving all possible values to \( b \).

The fluxional equation may be also expressed independently of \( a \), by eliminating this quantity by means of the two equations

\[
y^2 = ax + b, \quad \frac{dy}{dx} = \frac{a}{2y}.
\]

we then find

\[
\frac{dy}{dx} = \frac{y^2 - b}{2y}.
\]

This equation expresses a relation that subsists among the quantities \( x, y \) and \( \frac{dy}{dx} \) independently of any particular value of \( a \).

If the constant quantity which is eliminated is not of the first degree in the proposed equation, the result obtained will contain powers higher than the first of the fluxional coefficient \( \frac{dy}{dx} \). For example, let the equation be

\[
y^2 - 2ay + x^2 = a^2,
\]

Hence, by taking the fluxions, we find

\[
\frac{dy}{dx} = a + y \frac{dy}{dx} + x \frac{dx}{dx},
\]

therefore \( a = \frac{y \frac{dy}{dx} + x \frac{dx}{dx}}{\frac{dy}{dx}} \).

This value of \( a \) being substituted in the proposed equation, we find, after proper reduction,

\[
(x^2 - 2y^2) \frac{dy}{dx} - 4y \frac{dy}{dx} - x^2 = 0.
\]

This equation expresses the relation that ought to subsist between the variable quantity \( x \), its function \( y \) and its fluxional coefficient \( \frac{dy}{dx} \), independently of any particular value of \( a \).

By resolving the equation \( y^2 - 2ay + x^2 = a^2 \), in respect of \( a \), we have

\[
a = x - y \pm \sqrt{(2y^2 + x^2)}.
\]

As \( a \) is now separated from the variable quantities, it will disappear in taking the fluxion: accordingly we find

\[
- \frac{dy}{dx} = \frac{2y \frac{dy}{dx} + x \frac{dx}{dx}}{\sqrt{2y^2 + x^2}} = 0.
\]

When this expression is freed from the radical sign, it will appear to be the same as we have found by elimination.

50. Any number of constant quantities whatever, contained in an equation, may be made to disappear, by taking the fluxions as often as there are quantities to be exterminated.

Let \( y^2 = m(a^2 - x^2) \); by taking the fluxions we find

\[
\frac{dy}{dx} = -m \frac{x}{x}.
\]

Taking now the fluxions a second time, we get \( \frac{d^2y}{dx^2} + \frac{d^3y}{dx^3} = \frac{d^2y}{dx^2} = -m \); this value of \( -m \) being substituted in the former equation, it becomes

\[
\frac{d^2y}{dx^2} - x \frac{dy}{dx} - y \frac{d^2y}{dx^2} = 0,
\]

a result which is independent of the two constant quantities \( m \) and \( a \).

Investigation of Taylor's Theorem, and its Application to the Development of Functions.

51. The principle established in art. 38. and illustrated by various examples in art. 36. 37. and 38. leads immediately to an important application of the fluxional calculus, namely, the development of functions into series.

Let us consider, in the first place, the particular function \( x^n \), \( x \) being supposed variable, and \( n \) any constant quantity. We have found (art. 7.) that when \( x \) becomes \( x + h \), so that \( x^n \) becomes \( (x + h)^n \), then

\[
(x + h)^n = x^n + (nx^{n-1} + h) \frac{dx}{dx},
\]

where \( H \) is a function of \( x \) and \( h \), which vanishes when \( h = 0 \). As \( x \) and \( h \) are quantities which we suppose to be entirely independent of each other, this is an identical equation of the same nature as the equation

\[
(x + h)^n = x^n + (nx^{n-1} + h) \frac{dx}{dx},
\]

which will hold true, whatever values we give to \( x \) and \( h \). We may therefore, instead of \( h \) put \( k = x \), where \( k \) denotes also a quantity independent of \( x \). By this substitution, \( (x + h)^n \), the first member of the equation becomes \( k^n \); but as the form of the function \( H \) is unknown, we cannot actually make the substitution in all the terms of the second member; we may however suppose, that if it were made, the quantity \( n x^{n-1} + h \) would become \( X \), a function of \( x \) and \( k \), and then the equation will be

\[
k^n = x^n + X (k - x)
\]

an identical equation involving two indeterminate quantities \( x \) and \( k \), which, being quite independent of each other, we may regard \( k \) one of the two, as constant, and still the equation will be true whatever values we give to \( x \) the other quantity, which may be now considered as alone variable. This equation may therefore be treated exactly as the identical equations we have considered in art. 36. that is, we may take the fluxions of all the terms, and after dividing by \( dx \), we shall have a new identical equation; and this equation may be treated like the former, and so on as often as we please. Accordingly, taking the fluxions, considering \( k \) as constant, and observing that \( d (x^n) = nx^{n-1} dx \) (art. 26.) and that \( d \left\{ X (k - x) \right\} = (k - x) dX - X d(k - x) \) (art. 29. and 31.) we have

\[
0 = n x^{n-1} dx - X d x + (k - x) d X,
\]

and hence, dividing by \( dx \), and transposing \( X \), we get

\[
X = n x^{n-1} + (k - x) \frac{d X}{dx},
\]

a new identical equation, involving \( x \) and \( k \). We next take the fluxions of the terms of this equation exactly as before, considering \( k \) and \( dx \) as constant quantities, and get

\[
d X = n (n-1) x^{n-2} dx - d X + (k - x) \frac{d^2 X}{dx^2}.
\]

And hence we find, after dividing by \( dx \),
This is a new identical equation, which must hold true for every value of \( x \). From this equation we may derive another, just as we found the last from that before it, and so on. Thus a series of identical equations will be found, which, with the original equation from which they have been derived, will stand thus

\[ k^r = x^n + (k-x)x^n \]

\[ X = n x^{n-1} + (k-x) d X \]

\[ d X = (n-1) x^{n-2} + (k-x) d X \]

\[ 2 d X = n (n-1) x^{n-2} + (k-x) d X \]

\[ 3 d X = n (n-1) (n-2) x^{n-3} + (k-x) d X \]

\[ 4 d X = n (n-1) (n-2) (n-3) x^{n-4} + (k-x) d X \]

\&c.

From these equations, by eliminating one after another, the functions \( d X, d^2 X, d^3 X, \&c. \) of the following series of successive values of \( x \) are obtained.

\[ X = n x^{n-1} + (k-x) \frac{d X}{d x} \]

\[ X = n x^{n-1} + n (n-1) x^{n-2} + (k-x) \frac{d X}{d x} \]

\[ + \frac{(k-x)^3}{2} \cdot \frac{d X}{d x} \]

\[ X = n x^{n-1} + n (n-1) x^{n-2} + (k-x)^3 \frac{d X}{d x} \]

\[ + \frac{n(n-1)(n-2)}{2} x^{n-3} + (k-x)^3 \frac{d X}{d x} \]

\&c.

Hence, by substituting these expressions for \( X \) in the equation

\[ k^r = x^n + X (k-x) \]

we find

\[ k^r = x^n + n x^{n-1} (k-x) + (k-x)^3 \frac{d X}{d x} \]

\[ k^r = x^n + n x^{n-1} (k-x) + \frac{n(n-1)}{2} x^{n-2} (k-x)^3 \]

\[ + \frac{(k-x)^3}{2} \cdot \frac{d X}{d x} \]

\&c.

And again, by putting \( x+h \) instead of \( k \), and \( h \) for \( k-x \), but retaining still the hypothesis that the fluxional functions \( \frac{d X}{d x}, \frac{d^2 X}{d x^2}, \&c. \) are functions of \( x \) and \( k \), in which \( k \) is constant, we have

\[ (x+h)^r = x^n + n x^{n-1} h + h^r \frac{d X}{d x} \]

\[ (x+h)^r = x^n + n x^{n-1} h + \frac{n(n-1)}{2} x^{n-2} h^3 \]

\[ + \frac{(k-x)^3}{2} \cdot \frac{d X}{d x} \]

And in general, supposing the series to be continued to \( m \) terms, (without reckoning the term that contains the fluxional expression),

\[ (x+h)^r = x^n + n x^{n-1} h + \frac{n(n-1)}{2} x^{n-2} h^3 \]

\[ + \frac{n(n-1)(n-2)}{2} x^{n-3} h^3 \]

\[ + \frac{(k-x)^3}{2} \cdot \frac{d X}{d x} \]

\[ + \frac{n(n-1)(n-2)}{2} x^{n-3} h^3 \]

\[ + \frac{n(n-1)(n-2)(n-3)}{2} x^{n-4} h^4 \]

\[ + \frac{n(n-1)(n-2)(n-3)(n-4)}{2} x^{n-5} h^5 \]

\&c.

If we suppose this series to be continued indefinitely, then we have the binomial theorem in its common form (\textit{Algebra}, art. 316–322.), and in this case the quantity

\[ \frac{l^m}{2 \cdot 3 \cdot \ldots \cdot m-1} \cdot \frac{d^m x}{d x^m} \]

expresses the amount of all the terms of the series after the first \( m \) terms. For example, \( k^r \frac{d X}{d x} \) expresses the amount of all the terms following the second; and \( k^r \frac{d X}{d x} \) expresses the amount of all after the third, and so on.

When \( n \) is a whole number the series terminates, because then all the terms after the \((n+1)\)th term vanish. In this case the expression \( \frac{d^m x}{d x^m} \) or \( \frac{d X}{d x} \) ought to be equal to zero. To verify the truth of this conclusion, we must recollect, that because \( k^r = x^n + X (k-x) \); therefore \( X = x^n - \frac{k^n}{k-x} \); now, when \( n \) is a whole number, the numerator is exactly divisible by the denominator, so that

\[ X = k^n + \frac{k^n}{k-x} x^n + \frac{k^n}{k-x} x^n + \ldots + \frac{k^n}{k-x} x^n \]

and, hence, considering \( k \) as constant, we have

\[ \frac{d X}{d x} = \frac{k^n + 2 k^n}{k-x} x^n \]

\[ \frac{d X}{d x} = \frac{k^n + 2 k^n + 2 k^n}{k-x} x^n \]

\[ \frac{d X}{d x} = \frac{k^n + 2 k^n + 2 k^n + 2 k^n}{k-x} x^n \]

\&c.

By proceeding in this manner, we may express all the functions \( \frac{d^m X}{d x^m}, \frac{d^m X}{d x^m}, \&c. \) in terms of \( k \) and \( x \); and it is manifest, that the series which expresses each will have one term fewer than the series which expresses that before it, because of the constant quantities \( k^m, k^{m-1}, \&c. \) which have their fluxions \( = 0 \). As the series which expresses \( X \) has \( n \) terms, that which expresses \( \frac{d X}{d x} \) will consist of \( n-1 \) terms, and that which expresses \( \frac{d^2 X}{d x^2} \) will consist of \( n-2 \) terms, and so on to the value of \( \frac{d^m X}{d x^m} \), which will consist of a single term, viz.

\[ \left\{ \frac{(n-1)(n-2)(n-3)\ldots \text{to}(n-1) \text{factors}}{n!} \right\} \]

\[ \left\{ \begin{array}{c} \text{1, 2, 3, 4, \ldots} \text{to}(n-1) \end{array} \right\} \]

As this is a constant quantity, its fluxion will be \( = 0 \), therefore \( \frac{d^n X}{d x^n} \) will be \( = 0 \), as we had concluded that it ought to be.

When \( n \) is a fraction or negative, then \( X = \frac{k^n}{k-x} \) is still a fraction, when the numerator and denominator are each divided by their common factor. In this case, whatever be the number \( m \), the expression \( \frac{d^m X}{d x^m} \) can never be \( = 0 \); still, however, it may be calculated.

For example, if \( n = \frac{1}{2} \), then \( X = \frac{k^{1/2}}{k-x} = \frac{1}{k^{1/2} + x^{1/2}} \) therefore,

\[ \frac{d X}{d x} = \frac{-1}{2 x^{1/2} (k^{1/2} + x^{1/2})^3} \]

\[ \frac{d^2 X}{d x^2} = \frac{k^{1/2} + x^{1/2}}{4 x^{3/2} (k^{1/2} + x^{1/2})^3} \]

From the first of these expressions, we find
FLUXIONS.

Direct Method.

\[
\begin{align*}
(x + h)^{\frac{1}{2}} &= x^{\frac{1}{2}} + \frac{h}{2x^{\frac{1}{2}}} + \frac{h^2}{2x} - \frac{h^3}{8x^{rac{3}{2}}} + \cdots \\
\end{align*}
\]

and, in like manner, we may develop \((x+h)^{\frac{1}{2}}\) into as many terms as we please. This expression, and every other found by this theorem, is merely an identical equation, as will appear by reducing all the terms to a common denominator, for then it becomes \((x+h)^{\frac{1}{2}} = (x+h)^{\frac{1}{2}}\).

52. We might develop each of the functions, \(\log x, \quad a^x, \quad \sin x, \quad \cos x, \quad \) into series, in the same manner as we have developed \((x+h)^{\frac{1}{2}}\); but these, and every other function whatever of the form \(f(x+h), \) where \(x\) and \(h\) are indeterminate quantities independent of each other, may be included in one general formula, which we shall now investigate.

Let \(f(x), \) any function of a variable quantity \(x, \) be represented by \(u, \) so that we have \(f(x) = u, \) then, when \(x\) changes its value, and becomes \(x+h, \) we have seen (art. 19) that

\[
f(x+h) = f(x) + p + H)h
= u + (p + H)h,
\]

where \(p\) is a function of \(x\) that is independent of \(h, \) and \(H\) is a function of \(x\) and \(h, \) which vanishes when \(h=0.\)

Retracing now the substitutions and operations of article 51, let \(k=x+h, \) from which it follows that \(h=k-x);\) and let \(X\) be the value of \(p+H, \) when \(k=x\) is substituted in it for \(h.\) The equation thus becomes

\[
f(k) = u + X(k-x).
\]

As \(k\) is independent of \(x, \) the expression \(f(k)\) is to be considered as constant. \(u\) is a function of \(x\) only, and \(X\) is a function of \(x\) and \(k.\) Taking now the fluxions of the quantities \(u\) and \(X(k-x)\) relatively to \(x,\) and dividing by \(dx,\) we get, in the first place,

\[
o = \frac{du}{dx} - X + \frac{dX}{dx} (k-x),
\]

and hence again,

\[
X = \frac{du}{dx} + \frac{dX}{dx} (k-x).
\]

Considering now \(dx\) as a constant quantity, and taking the fluxions repeatedly, and dividing by \(dx\) as before, we find, as in art. 51,

\[
\begin{align*}
2 \frac{dX}{dx} &= \frac{d^3u}{dx^3} + (k-x) \frac{d^3X}{dx^3}, \\
3 \frac{d^2X}{dx^2} &= \frac{d^4u}{dx^4} + \frac{1}{2} (k-x) \frac{d^4X}{dx^4}, \\
4 \frac{d^3X}{dx^3} &= \frac{d^5u}{dx^5} + \frac{1}{3} (k-x) \frac{d^5X}{dx^5}, \\
&\quad \ldots
\end{align*}
\]

Hence, we have this series of equations

\[
\begin{align*}
X &= \frac{du}{dx} + \frac{dX}{dx} (k-x), \\
\frac{dX}{dx} &= \frac{d^2u}{dx^2} + \frac{1}{2} (k-x) \frac{d^2X}{dx^2}, \\
\frac{d^2X}{dx^2} &= \frac{d^3u}{dx^3} + \frac{1}{3} (k-x) \frac{d^3X}{dx^3}, \\
\frac{d^3X}{dx^3} &= \frac{d^4u}{dx^4} + \frac{1}{4} (k-x) \frac{d^4X}{dx^4}, \\
&\quad \ldots
\end{align*}
\]

These equations, when combined with the equation

\[
f(k) = u + X(k-x),
\]

give us

\[
f'k = u + \frac{du}{dx} (k-x) + \frac{dX}{dx} (k-x),
\]

and hence again, by substituting \(x+h\) for \(k,\) but still retaining \(k\) in the function \(X,\) so that

\[
X = \frac{f(k)-u}{k-x} = \frac{f(k)-f(x)}{k-x},
\]

where \(k\) is to be considered as a constant quantity, and \(x\) alone as variable, we have

\[
\begin{align*}
&f(x+h) = u + \frac{du}{dx} h + \frac{dX}{dx} h, \\
&f(x+h) = u + \frac{du}{dx} h + \frac{d^2u}{dx^2} h^2 + \frac{dX}{dx} h, \\
&f(x+h) = u + \frac{du}{dx} h + \frac{d^2u}{dx^2} h^2 + \frac{d^3u}{dx^3} h^3 + \frac{dX}{dx} h, \\
&f(x+h) = u + \frac{du}{dx} h + \frac{d^2u}{dx^2} h^2 + \frac{d^3u}{dx^3} h^3 + \frac{d^4u}{dx^4} h^4 + \frac{dX}{dx} h, \\
&\quad \ldots
\end{align*}
\]

If we suppose the series to proceed \(ad infinitum,\) then, without paying any regard to the expression \(\frac{d^mX}{dx^m},\)

which enters into each finite development of the function, we have

\[
\begin{align*}
f(x+h) &= u + \frac{du}{dx} h + \frac{d^2u}{dx^2} h^2 + \frac{d^3u}{dx^3} h^3 + \frac{d^4u}{dx^4} h^4 + \ldots
\end{align*}
\]

This formula, remarkable for its elegance and simplicity, was first found by Dr. Taylor, an eminent English mathematician, who published it in a work called Methodus Incrementorum, about the year 1716, and is commonly called Taylor's Theorem. Sir Isaac Newton gave a similar formula in his Principia, where he treats of the theory of comets, but it is applicable to a series of quantities having finite differences. Newton's formula becomes Taylor's theorem, when the differences are indefinitely small. This theorem has considerably excited the attention of mathematicians ever since the late Mr. Lagrange proposed to make it the basis of the fluxional or differential calculus, first in the Memoirs of the Berlin Academy for 1772, and afterwards in his Théorie des Fonctions Analytiques. The demonstration of it given here, is taken from a Memoir by M. Ampère, published in the thirteenth Cahier of the Journal de l'École Polytechnique. It is simple and very elegant. Lagrange has also given an elegant demonstration, which has been improved by M. Poisson, and is now equally complete as that which we have here adopted, but more diffuse.

53. We shall now apply Taylor's theorem to the development of the five elementary functions, which have so often come under our consideration.

1st. Let \(f(x) = a^x,\) then, (rule \(A\) art. 26),

\[
\begin{align*}
&\frac{du}{dx} = na^{x-1}, \\
&\frac{d^2u}{dx^2} = n(n-1)a^{x-2}, \\
&\frac{d^3u}{dx^3} = n(n-1)(n-2)a^{x-3},
\end{align*}
\]

&c.
Therefore, by the formula, \( f(x+h) \), that is, \((x+h)^a = x^a + ax^{a-1}h + \frac{n(n-1)}{1 \cdot 2} x^{a-2} h^2 + &c.\)
the same expression as we have already found, (preceding article).

2d. Let \( f(x) = u = \log x \), then supposing \( b \) to be the basis of the system, and putting \( B \) for \( \log \) \( \frac{b}{a} \), we have, by rules (B) and (A), art. 26,
\[
\frac{d}{dx} \left( x^a \right) = B x^a
\]
\[
\frac{d}{dx} \left( x^{a-1} \right) = B x^{a-1}
\]
\[
\frac{d}{dx} \left( x^{a-2} \right) = B x^{a-2}
\]
\[
\frac{d}{dx} \left( x^{a-3} \right) = B x^{a-3}
\]
\[
\frac{d}{dx} \left( x^{a-4} \right) = B x^{a-4}
\]
Therefore, substituting these expressions in the general formula, we get \( f(x+h) \), or \( \log (x+h) \) =
\[
\log x + \frac{h}{x} \left\{ \frac{h}{2} \left( \frac{h}{2} - \frac{h^2}{3x} + \frac{h^3}{4x^3} + &c. \right) \right\}
\]
By transposing the first term \( \log x \), and observing that
\[
\log (x+h) - \log x = \log \frac{x+h}{x} = \log (1 + \frac{h}{x})
\]
this formula becomes
\[
\log \left( 1 + \frac{h}{x} \right) = \frac{h}{x} \left\{ \frac{h}{2} - \frac{h^2}{3x} + \frac{h^3}{4x^3} + &c. \right\}
\]
From this series, every thing relative to the calculation of logarithms may be found, as we have shown in our article Algebra.

3d. Next, let \( f(x) = u = a^x \), let \( A = \log a \); then, by rule (C), art. 26,
\[
\frac{d}{dx} \left( x^a \right) = A a^x
\]
\[
\frac{d}{dx} \left( x^{a-1} \right) = A a^x
\]
\[
\frac{d}{dx} \left( x^{a-2} \right) = A a^x
\]
\[
\frac{d}{dx} \left( x^{a-3} \right) = A a^x
\]
\[
\frac{d}{dx} \left( x^{a-4} \right) = A a^x
\]
Therefore, substituting in the general formula, we find
\[
f(x+h) \) or \( a^{x+h} = a^x \left( 1 + \frac{h}{a} \right) =
\[
a^x \left\{ 1 + \log a + \log \left( 1 + \frac{h}{a} \right) \right\}
\]
\[
\left( \frac{h}{2} + \frac{h^2}{3x} + \frac{h^3}{4x^3} + &c. \right)
\]
Let both members of this equation be divided by \( a^x \), and then changing \( h \) into \( x \), we have
\[
a^x = 1 + \log a + \frac{h}{2} + \frac{h^2}{2.3} + \frac{h^3}{2.3.4} + &c.
\]
If we suppose \( x = 1 \), then,
\[
a = 1 + \log a + \frac{h}{2} + \frac{h^2}{2.3} + &c.
\]
and if we make \( x = \frac{1}{a} \), then,
\[
a^x = 1 + \frac{1}{a} + \frac{1}{2} + \frac{1}{2.3} + \frac{1}{2.3.4} + &c.
\]
Thus the quantity \( a^x \) is a constant number, which is the value of \( a \), when \( A = 1 \). By taking the sum of a sufficient number of terms of the series, we find \( a^x \) =
\[
2.718281828459046
\]
Let this number be denoted by \( e \), and then \( a^x = e^x \). As \( A \) is the Napierian logarithm of \( a \), \( e \) must be the basis or radical number in Napier’s system. We have found its value by a different mode of proceeding in art. 12. Since \( ae = e^x \), therefore \( e^x = e^{ax} \); putting \( x \) instead of \( A \), hence, an exponential quantity, of which the basis is any number \( a \), may be transformed into another, having the determinate number \( e \) for its basis, which is such that \( l(e) = 1 \). On this account, the number \( e \) is an important element in analysis.

4th. Suppose now that \( f(x) = u = \sin x \), by rule (D) art. 26, we have
\[
d \frac{d}{dx} \left( \cos x \right) = -\sin x
\]
\[
d \frac{d}{dx} \left( \sin x \right) = \cos x
\]
\[
d \frac{d}{dx} \left( \cos x + \sin x \right) = \cos x + \sin x
\]
\[
d \frac{d}{dx} \left( \cos x - \sin x \right) = \cos x - \sin x
\]
Therefore, in this case, the general formula gives
\[
f(x+h) = \sin (x+h) =
\[
\sin x + \frac{h}{2} \cos x - \frac{h^2}{2} \sin x - \frac{h^3}{2} \cos x + &c.
\]
5th. Let \( f(x) = u = \cos x \), then, rule (D) art 26,
\[
d \frac{d}{dx} \left( \sin x \right) = \cos x
\]
\[
d \frac{d}{dx} \left( \cos x \right) = -\sin x
\]
\[
\frac{d}{dx} \left( \sin x + \cos x \right) = \sin x + \cos x
\]
\[
\frac{d}{dx} \left( \sin x - \cos x \right) = \sin x - \cos x
\]
and hence \( f(x+h) = \cos (x+h) =
\[
\cos x - \sin x + \frac{h}{2} \cos x - \frac{h^2}{2} \sin x + &c.
\]
If we put
\[
P = 1 - \frac{h^2}{2} + \frac{h^4}{2.3.4} - \frac{h^6}{2.3.4.5.6} + &c.
\]
\[
Q = \frac{h^2}{2.3} + \frac{h^4}{2.3.4.5} - \frac{h^6}{2.3.4.5.6.7} + &c.
\]
these developments of the functions \( \sin (x+h) \) and \( \cos (x+h) \) become
\[
\sin (x+h) = P \sin x + Q \cos x
\]
\[
\cos (x+h) = P \cos x - Q \sin x
\]
But, by the Arithmetic of Sines,
\[
\sin (x+h) = \cos x + \sin x \sin h \cos x
\]
\[
\cos (x+h) = \sin x \sin h \cos x
\]
From these equations we get
\[
P \cos h \sin x + (Q - \sin h) \cos x = 0
\]
\[
(P - \cos h) \cos x - (Q - \sin h) \sin x = 0
\]
and hence, again,
\[
-P \cos h \sin x + Q \sin h = 0
\]
therefore, \( \cos h = P \); \( \sin h = Q \), that is, putting \( x \) instead of \( h \),
\[
\cos x = 1 - \frac{x^2}{2} + \frac{x^4}{2.3.4} - \frac{x^6}{2.3.4.5} + &c.
\]
\[
\sin x = \frac{x}{2} + \frac{x^3}{2.3.4} - \frac{x^5}{2.3.4.5} + &c.
\]
54. Resuming Taylor’s theorem, viz.
\[
f(x+h) = u + \frac{du}{dx} h + \frac{d^2 u}{dx^2} h^2 + \frac{d^3 u}{dx^3} h^3 + &c.
\]
where \( u \) denotes \( f(x) \).
Let us suppose that when \( x = 0 \), then \( f(x) \), or \( u \), becomes \( U \); and that, upon the same hypothesis, the functions \( \frac{du}{dx} \), \( \frac{d^2 u}{dx^2} \), \( \frac{d^3 u}{dx^3} \), &c. become \( U' \), \( U'' \), \( U''' \), &c. respectively. The theorem then gives us, when \( x = 0 \),
\[
f(h) = U + U' h + U'' h^2 + U''' h^3 + &c.
\]
As $h$ denotes here any quantity whatever, we may put $x$ instead of $h$, and then we have

$$f(x) = U + U'x + U''x^2 + \frac{1}{2}U'''x^3 + \frac{1}{3}U''''x^4 + \&c.$$ 

This elegant formula for the development of a function, has, of late years, been ascribed by the French mathematicians to our ingenious countryman, Maclaurin, who gave it in his Treatise of Fluxions, Book II. Art. 751. (printed in 1742). We observe, however, that Maclaurin seems to consider it as identical with Taylor's theorem, to which indeed it is closely allied. It appears to have been little attended to, until the celebrated La Place brought it into notice, by employing it about the year 1777, in a memoir on the development of functions; and it is now commonly denominated, by the French writers, Maclaurin's theorem.

55. To exemplify the utility of this theorem, let us suppose, 1st. that $f(x) = u = (a + x)^n$, $n$ being any constant quantity, then

$$\frac{d^n u}{dx^n} = n! (a+x)^{n-1} = \frac{n}{1!} \frac{n}{2!} (a+x)^{n-2} + \&c.$$ 

when $x = 0$, then $u = (a + x)^n$ becomes $a^n$ which is therefore the value $U$. Also, by making $x = 0$ in the values

$$\frac{d^n u}{dx^n} = \frac{d^n u}{dx^n} = \frac{d^n u}{dx^n} = \frac{d^n u}{dx^n} = \&c.$$ 

we get

$$U = n! a^{n-1}, \ U' = n (n-1) a^{n-2}, \ U'' = n! (n-1)(n-2) a^{n-3}, \ &c.$$ 

These expressions, when substituted in the general theorem, give us

$$(a+x)^n = a^n + n a^{n-1} + \frac{n}{2} a^{n-2} + \frac{n(n-1)}{2} a^{n-3} + \&c.$$ 

Thus we have another demonstration of the binomial theorem.

56. Next let it be required to develop the function $\log (a + x)$ into a series. In this case, putting $B$ for $(a + x)$ (being the basis of the system), we have

$$\log (a + x) = \frac{1}{B} \left( a + x - \frac{x^2}{2} - \frac{x^3}{3} - \&c. \right)$$

The last expression was found in Art. 53.

3d. Next, let $f(x) = u = a^x$; then putting $A$ for

$$\frac{d^n u}{dx^n} = A^x \frac{d^n u}{dx^n} = A^x \frac{d^n u}{dx^n} = A^x \frac{d^n u}{dx^n} = \&c.$$ 

when $x = 0$, then $a^x$ becomes $1$; in like manner we find

$$U = \frac{d^n u}{dx^n} = \frac{d^n u}{dx^n} = \frac{d^n u}{dx^n} = \frac{d^n u}{dx^n} = \&c.$$ 

Hence, from the formula, we get

$$\log (a + x) = \log a + \frac{1}{B} \left( x - \frac{x^2}{2a} + \frac{x^3}{3a} - \&c. \right)$$

the same expression as was found in Art. 53.

Now when $x = 0$, then $a^x = 1$, therefore, in this case,

$$U = 1, \ U' = A^x, \ U'' = A^x a, \ U''' = A^x a^3, \ &c.$$ 

and substituting these in the general formula, we get

$$a^x = 1 + A^x + \frac{a^x}{2} + \frac{a^x}{3} + \&c.$$ 

4th. Let $f(x) = u = \sin x$; in this case

$$\frac{d^n u}{dx^n} = \sin x, \ \frac{d^n u}{dx^n} = \cos x, \ \frac{d^n u}{dx^n} = \&c.$$ 

Now, when $x = 0$, then $\sin x = 0$, and $\cos x = 1$, therefore,

$$U = 0, \ U' = 1, \ U'' = 0, \ U''' = -1, \ U'''' = 0, \ &c.$$ 

and the general formula gives in this case

$$\sin x = x - \frac{x^3}{3} + \frac{x^5}{5} - \frac{x^7}{7} - \&c.$$ 

5th. If $f(x) = \cos x$, then

$$\frac{d^n u}{dx^n} = \sin x, \ \frac{d^n u}{dx^n} = \cos x, \ &c.$$ 

When $x = 0$, then $\cos x = 1$, and $\sin x = 0$, therefore,

$$U = 1, \ U' = 0, \ U'' = -1, \ U''' = 0, \ U'''' = 1, \ &c.$$ 

and $\cos x = \frac{1}{2} - \frac{x^2}{2} + \frac{x^4}{24} - \&c.$

In like manner, we may develop the function $u = \tan x$, and $u = \sec x$, into series; but the expressions

$$\frac{d^n u}{dx^n} = \frac{d^n u}{dx^n} = \&c.$$ 

will be more complex than in these examples. On the other hand, we may find series which shall express the arc by means of the cosine, the sine, or the tangent, &c. We select the last as the most simple. Let $f(x) = u = \arctan x$, of which the tangent is $x$: then

$$\tan x = x, \ \text{and} \ \frac{d^n u}{dx^n} = \text{sec}^n x.$$ 

For 2. $\sin u \cos u$, we have

$$\frac{d^n u}{dx^n} = \cos^2 u \sin 2u.$$ 

From this equation, by taking the fluxions (by rule (F) art. 29. and rules (A), (D) art. 26.), we get

$$\frac{d^n u}{dx^n} = \cos u = \sin u.$$ 

Let the value of $d^n u$ be substituted instead of it in the second member, and also $\cos 3u$ instead of $\cos 2u \sin u$, to which it is equal, (Arithmetical of Sines, art. 7.), then dividing by $dx$, we have

$$\frac{d^n u}{dx^n} = \cos 3u \cos 3u.$$ 

From this equation, again, by proceeding as before, we find

$$\frac{d^n u}{dx^n} = \cos 4u.$$ 

Now when $x = 0$, then $u = 0$, and $\cos u = \cos 3u$, $\cos 5u$, &c. are each $= 1$; also $\sin u, \sin 2u, \sin 4u, \&c.$ are each $= 0$. Hence, from the formula (1), (2), (3), (4), &c. we have

$$U = 0, \ U' = 1, \ U'' = 0, \ U''' = -2, \ U'''' = 0, U''' = 2, \ U'''' = 2.3.4,$$ 

&c. and recurring to the general formula, we get in this case

$$U = \frac{1}{\arctan x} = x - \frac{x^3}{3} + \frac{x^5}{5} - \frac{x^7}{7} \&c.$$ 

The preceding investigation affords an elegant example of the utility of the arithmetical of sines in the fluxional calculus.
56. In the examples to which we have applied Maclaurin's theorem, the quantities \( U, U', \ldots \) have all finite values. If in any case one or more of them have an infinite value, we may conclude that the function does not admit of being expressed by a series, the terms of which are positive integer powers of \( x \). The function \( u = f(x) \) is of this nature; for, from it we get

\[
\frac{du}{dx} = \frac{1}{x}, \quad \frac{d^2u}{dx^2} = -\frac{1}{x^2}, \quad \frac{d^3u}{dx^3} = \frac{2}{x^3}, \quad \&c. \text{ The supposition that } x = 0 \text{ renders } \frac{du}{dx} = 1 \text{ an infinite quantity; in like manner the quantities } \frac{d^2u}{dx^2}, \frac{d^3u}{dx^3}, \&c. \text{ become all infinite as well as the function } u \text{ itself.}
\]

The quantities denoted by the symbols \( \frac{du}{dx}, \frac{d^2u}{dx^2}, \&c. \) only become infinite, however, when particular values are given to \( x \); therefore it will always be possible, by Taylor's theorem, to develop any function \( f(x+h) \) into a series proceeding by the integer and positive powers of \( h \), provided we suppose \( x \) to be an indeterminate quantity; when, by giving it a definite value, the coefficients of \( h \) become infinite, it may be concluded, that although in general the determination may be developed into a series, the terms of which contain only the integer and positive powers of \( h \), in that particular case, it will not admit of being so expressed. For example, let \( u = b + (x-a)^3 \); then, when \( x \) becomes \( x+h \), we have \( b + (x+h-a)^3 \) for the new value or the second state of the function; and because in this case

\[
\frac{du}{dx} = \frac{1}{2(x-a)^3}, \quad \frac{d^2u}{dx^2} = -\frac{3}{(x-a)^4}, \quad \&c. \text{ by Taylor's theorem, we have,}
\]

\[
b + (x+h-a)^3 = b + (x-a)^3 + \frac{1}{2(x-a)^2} + \frac{1}{8(x-a)^3} h + \&c.
\]

In the particular case of \( x = a \), or \( x-a = 0 \), the quantity to be developed, viz. \( b + (x+h-a)^3 \), becomes \( b + h^3 \), an expression containing a fractional power of \( h \), and which has the twofold value \( b + h \) and \( b - h \), because the sign of a square root may be taken either + or -. As the development contains only positive integer powers of \( h \), relatively to this quantity, it can only have a single value, and therefore it is impossible that it should express the function in this particular case. Accordingly, when we make \( x = a \) in the development, its first term \( u = b + (x-a)^3 \) becomes \( b \); but the coefficient of its second term, viz.

\[
\frac{du}{dx} = \frac{1}{2(x-a)^2},
\]

becomes \( \frac{1}{2(0)^2} = \infty \), a quantity infinitely great, and the same is true also of the coefficients of the third and following terms. Thus the analytical fact, that the development cannot in this particular case represent the function, is indicated by its terms failing to express anything definite. If, however, we give to \( x \) any value, except that of \( x = a \), the function is correctly expressed by its development.

Next, let the function be \( u = \frac{b}{(x-a)^3} \); in this case,

\[
\frac{du}{dx} = -\frac{2b}{(x-a)^4} \cdot \frac{d^2u}{dx^2} = \frac{6b}{(x-a)^5} \text{, &c. therefore the general development of } (x+h-a)^3 \text{ (the second state of the function) is}
\]

\[
b + \frac{2b}{(x-a)^2} h + \frac{2b}{(x-a)} h^2 + \&c.
\]

In the particular case of \( x = a \), every term of the development becomes infinite; but then the value of the quantity indicated by the development is \( \frac{b}{h^2} = b h^{-2} \), an expression in which the exponent of \( h \) is negative. As the development contains only positive powers of \( h \), it could not express the new value of the function in this particular case. When \( x \) has any other value, the general development will always hold true.

As a general formula commonly contains all individual cases, it has been regarded as in some measure a paradox in analysis, that the general development of any function of a variable quantity should not apply to every particular value of that quantity; and in such cases, it is usual to say that Taylor's theorem fails, that is, in its application. Lagrange first cleared up this point, and shewed that, when, by giving a particular value to \( x \), the new state of the function contains terms of the form \( P h^{-a} \) or \( Q h^m \), that is, negative or fractional powers of \( h \), then, from the very nature of the calculus, all the coefficients of the general development, after a certain term, will become infinite. On the other hand, when a particular value of \( x \) renders the coefficients infinite, we may conclude that the development ought, in that particular case, to contain fractional or negative powers of \( h \).

Of Vanishing Fractions, &c.

57. A vanishing fraction is a fractional function of a variable quantity \( x \) of such a form, that its numerator and denominator become both \( 0 \) when a particular value is given to \( x \). Such, for example, is this

\[
\frac{x^3 - a^3}{x^2 - a^2}
\]

which when \( x = a \) becomes \( 0 \); however, by remarking that \( x^3 - a^3 = (x-a)(x+a)(x+a) \), it will appear that

\[
\frac{x^3 - a^3}{x^2 - a^2} = \frac{x+a}{x},
\]

so that the value of the fraction when \( x = a \) is in fact \( a + a = 2a \), hence it appears that the fraction has in this case a real assignable value; and we also see that it assumes the form \( \frac{0}{0} \) only because its numerator and denominator have a common factor, which is then \( 0 \).

The fraction \( \frac{x^3 - a^3}{a x^2 - a^3} \) has also the property of becoming \( \frac{0}{0} \) when \( x = a \). The numerator and denominator have a common divisor \( x-a \), and this being taken out of both, the fraction is changed to \( \frac{a}{a} \):

Upon the supposition that \( x = a \), this last quantity becomes manifestly \( 0 \). Therefore, when \( x = a \), the fraction \( \frac{x^3 - a^3}{a x^2 - a^3 + x^2} \) becomes \( 0 \).
Again, this other fraction \( \frac{a x^2 - a^2}{x^2 - 2a x + a^2} \) becomes \( \frac{0}{0} \) when \( x = a \); but by taking the common divisor \( x - a \) out of the numerator and denominator, the fraction is changed to \( \frac{a}{x-a} \); and this expression when \( x = a \) becomes \( \frac{a}{0} \) an infinite quantity.

Hence we see that a vanishing fraction may in some cases have a finite value, and that in others it may be nothing, or infinite; but in every case its value may be determined by freeing the numerator and denominator from the factors common to both. When the terms of the fraction are rational functions of \( x \), this may be done by finding their common measure, as is taught in Algebra, art. 72. But when they are irrational or transcendental quantities, this method fails.

58. Let \( \frac{P}{Q} \) denote generally a fraction, the terms of which \( P \) and \( Q \) are functions of \( x \), that vanish when \( x = a \), some given quantity. Suppose \( x \) to become \( x + h \), then, by Taylor's theorem, \( P \) becomes \( P' + \frac{d P}{d x} h + \frac{d^2 P}{d x^2} \frac{h^2}{2} + \&c. \) and \( Q \) becomes \( Q' + \frac{d Q}{d x} h + \frac{d^2 Q}{d x^2} \frac{h^2}{2} + \&c. \) and the fraction becomes

\[
\frac{P' + \frac{d P}{d x} h + \frac{d^2 P}{d x^2} \frac{h^2}{2} + \&c.}{Q' + \frac{d Q}{d x} h + \frac{d^2 Q}{d x^2} \frac{h^2}{2} + \&c.}
\]

Let us denote the fluxional coefficients \( \frac{d P}{d x}, \frac{d^2 P}{d x^2} \&c. \) by \( P', P'', \&c. \) and \( \frac{d Q}{d x}, \frac{d^2 Q}{d x^2} \&c. \) by \( Q', Q'', \&c. \) then observing that when \( x = a \), \( P = 0 \), \( Q = 0 \), we have, after dividing by \( h \),

\[
\frac{P'}{Q'} + \frac{P''}{Q''} + \&c. \]

for the new value of the fraction. If we make \( h = 0 \), this expression becomes simply \( \frac{P}{Q} \), which must be the value of the fraction \( \frac{P}{Q} \) when \( x = a \), because it is evidently the same thing to suppose first, that \( x = x + h \), and afterwards that \( x = a \) and \( h = 0 \), as to suppose at once that \( x = a \). If it happen that one of the two quantities \( P', Q' \), is equal to 0, then the fraction \( \frac{P}{Q} \) is either nothing, or infinite; but if both are \( \neq 0 \), then, after rejecting \( P' \) and \( Q' \) from the general expression, and dividing again by \( h \), we have \( \frac{P}{Q} \) for the value of the fraction, in the case of \( x = a \); and so on. Hence this rule.

To find the value of \( \frac{P}{Q} \), a fraction which becomes \( \frac{0}{0} \) when \( x = a \). Divide the fluxion of the numerator by that of the denominator, let the result be \( \frac{P'}{Q'} \); then if this expression does not become \( \frac{0}{0} \) when \( a \) is substituted for \( x \), it is the value sought; but if it does treat this fraction in all respects as the other was treated, deducing from it a new fraction \( \frac{P''}{Q''} \) and proceed in this manner, until an expression be found which does not become \( \frac{0}{0} \) by the substitution of \( a \) for \( x \); and the first expression that occurs having this property is the value sought.

Ex. 1. The sum of \( n \) terms of the series \( 1 + x + x^2 + x^3 + \&c. \) is \( \frac{1}{1-x} \). If we suppose \( x = 1 \), this expression becomes \( \frac{0}{0} \). It is required to find in this case its value. Here \( P = x^n - 1 \), \( Q = x - 1 \). therefore \( d P = n x^{n-1} dx \), \( d Q = dx \), and \( \frac{d P}{d Q} = \frac{n x^{n-1} dx}{dx} = \frac{P'}{Q'} \). This expression, when 1 is put for \( x \), becomes \( \frac{n}{1} = n \), which is the value sought, as is otherwise sufficiently evident.

Ex. 2. Let the fraction be \( \frac{a x^2 + a c^2 - 2 a c x}{b x^2 - 2 b c x + b c^2} \), which becomes \( \frac{0}{0} \) when \( x = c \). In this case,

\[
d P = \frac{(2 ax - 2ac)dx}{dx} \quad \text{and} \quad d Q = \frac{(2bx - 2bc)dx}{dx} \quad \text{and} \quad \frac{d P}{d Q} = \frac{P'}{Q'}.
\]

This fraction \( \frac{P}{Q} \), becomes also \( \frac{0}{0} \), when \( x = c \), therefore, proceeding as before, \( d P = a dx \); \( d Q = b dx \); and \( \frac{d P}{d Q} = \frac{a}{b} \), which is the value sought.

Ex. 3. The fraction \( \frac{a^2 - b^2}{x} \) becomes \( \frac{0}{0} \) when \( x = 0 \).

Here

\[
d P = \left\{ a(1, (a) - b(1, (b)) \right\} dx \quad \text{and} \quad d Q = dx;
\]

when \( x = 0 \), \( \frac{P}{Q} \) becomes \( 1 \), \( a(1, (a) - b(1, (b)) = 1 \left( \frac{a}{b} \right) \), which is the value required.

59. The rule of last article will not in general apply, if Taylor's theorem does not give the developements of the functions \( P, Q \) in the case of \( x = a \). When this happens, we may substitute \( a + h \), instead of \( x \), in the fraction \( \frac{P}{Q} \), and develop the numerator and denominator into ascending series of the form \( A h^m + B h^n + C h^p + \&c. \) \( A'H^{m'} + B'H^{n'} + C'h^{p'} + \&c. \). We have then, instead of \( \frac{P}{Q} \), this other fraction,

\[
A h^m + B h^n + C h^p + \&c.
\]

or, dividing the numerator and denominator by \( h^m \),

\[
A h^{m-m} + B h^{n-m} + C h^{p-m} + \&c.
\]

Under this form, it is easy to see, that if \( m \) be greater than \( m' \), the supposition that \( h = 0 \), makes the fraction \( 0 \); and that if \( m = m' \), the same supposition reduces the fraction to \( \frac{1}{1} \) because whatever be the value of \( h \), \( h^{m-m} = 1 \); lastly, if \( m \) be less than \( m' \), so that \( m - m' \) is negative, then, when \( h = 0 \), the fraction becomes infinite. Hence this rule.
FLUXIONS.

Seek the first terms of the ascending series, which are the developments of the numerator, and denominator when \( a+h \) is substituted in them instead of \( x \). Reduce to its lowest terms the new fraction formed from these first terms, and then make \( h=0 \); the result will be the value of the fraction when \( x=0 \). And this rule will apply in every case.

Example. Let the fraction be

\[
\frac{x^3+2a^2x^2+2a^3}{2a^2x^3+2a^3x^2+2a^4}
\]

and let its value be sought when \( x=0 \). When \( a+h \) is substituted for \( x \), the fraction becomes

\[
\frac{(a^2+2ah+h^2)}{2a^2x^3+2a^3x^2+2a^4}
\]

Now, by the binomial theorem,

\[
\sqrt{a^2+2ah} = a + \frac{h}{2a} + \frac{h^2}{8a^2} + \text{&c.}
\]

\[
\sqrt{(a^2+2ah+h^2)} = a + \frac{h}{2a} + \frac{h^2}{8a^2} + \text{&c.}
\]

When these series are substituted for the radical quantities, and \( h \) is made \( =0 \), we get \( -5a \) for the value of the fraction.

60. If \( P \) and \( Q \) are functions of \( x \), such that when \( x=a \), then \( P=0 \), and \( Q=\infty \), which is expressed by the character \( \infty \), it may be proposed to find the value of the function \( PQ \), in that particular case. Put \( R=\frac{P}{Q} \); then the value of \( x \), which renders \( R \) infinite, will make \( R=0 \); and as \( PQ=\frac{P}{R} \), the value of \( x \), which makes \( PQ=0 \times \infty \), will make \( \frac{P}{R}=0 \). The problem may therefore be solved by the rules of art. 58, and art. 59.

Ex. Supposing \( x \) to represent a semicircle, and \( x \) any arc, the expression \((1-x^2) \times \tan(\frac{1}{2}x) \) becomes \( 0 \times \infty \) when \( x=1 \). Here \( P=1-x^2, Q=\tan(\frac{1}{2}x), R=\frac{1}{Q} \), and \( \tan(\frac{1}{2}x) \); and when \( x=1 \) this expression becomes \( 0 \).

\[
\frac{dy}{dx} = \frac{\frac{1}{2} \sin^{-1}(\frac{1}{2}x)}{\frac{1}{2} \sin^{-1}(\frac{1}{2}x)}
\]

Hence, in the case of \( x=1 \), we have

\[
\frac{dy}{dx} = \frac{1}{\pi}
\]

For the greatest and least values of a function.

61. If \( y \) be a function of a variable quantity \( x \), of such a nature, that \( x \) being supposed to increase or decrease continually, \( y \) increases to a certain value, but afterwards decreases; when \( y \) has that extreme value, it is said to be a maximum. And, on the other hand, if \( y \) decrease to a certain value, and then increase; when it has that particular value, it is said to be a minimum.

The co-ordinates of a plane curve may conveniently be employed to indicate the relative changes of magnitude in a variable quantity, and of the function of that quantity. In Plate CCLV. Fig. 1, let CQD be a curve, referred to an axis AB, and such that, if any abscissa AP is taken to represent \( x \); the corresponding ordinate PQ may represent the function \( y \). Also, let us suppose that the curve recedes from the axis in that part of it between \( C \) and \( Q \), and then approaches between \( Q \) and \( Q' \); and again recedes between \( Q' \) and \( Q'' \), and returns towards the axis in the branch \( QD \); and so on. Suppose now the ordinate PQ to move parallel to itself from C along the axis, it will increase from \( C \) to \( Q' \); in the position \( PQ' \), it will be a maximum; then it will decrease, and in the position \( PQ'' \) it will be a minimum; afterwards it will increase, and again be a maximum in the position \( PQ''' \), and so on; that it may have various maxima and minima unequal among themselves, the essential character of a maximum consisting in this, that the values which immediately precede, or which immediately follow it, are smaller; on the contrary, the minimum is exceeded by the values which immediately precede and follow it.

62. It is an immediate consequence of this characteristic property, that if \( a \) be the value of \( x \), which renders \( y \) a maximum or minimum, and if \( a+h \), and also \( a-h \) be substituted instead of \( x \) in the function, then both results will be less than a maximum value of \( y \), but they will be both greater than a minimum value. Now, whatever be the value of \( x \), if \( x+h \) and \( x-h \) be substituted instead of \( x \) in the function \( y \); by Taylor's theorem, (art. 52.) it will become in the one case,

\[
y + \frac{dy}{dx} + \frac{d^2y}{dx^2} \frac{h^2}{2} + \frac{d^3y}{dx^3} \frac{h^3}{6} + \text{&c.}
\]

and in the other,

\[
y - \frac{dy}{dx} + \frac{d^2y}{dx^2} \frac{h^2}{2} - \frac{d^3y}{dx^3} \frac{h^3}{6} + \text{&c.}
\]

Therefore, when \( a \) is substituted for \( x \) in these two developments, they will both be less than a maximum value of the function, and both greater than a minimum value; but when this substitution is made, the first term \( y \) becomes, by hypothesis, the maximum or minimum value. Therefore, in the case of a maximum, we must have

\[
y + \frac{dy}{dx} + \frac{d^2y}{dx^2} \frac{h^2}{2} + \frac{d^3y}{dx^3} \frac{h^3}{6} + \text{&c.} \geq \text{y,}
\]

\[
y - \frac{dy}{dx} + \frac{d^2y}{dx^2} \frac{h^2}{2} - \frac{d^3y}{dx^3} \frac{h^3}{6} + \text{&c.} \leq \text{y;}
\]

and taking \( y \) from each side,

\[
\frac{d^2y}{dx^2} \frac{h^2}{2} + \frac{d^3y}{dx^3} \frac{h^3}{6} + \text{&c.} \geq 0,
\]

and similarly in the case of a minimum,

\[
\frac{d^2y}{dx^2} \frac{h^2}{2} - \frac{d^3y}{dx^3} \frac{h^3}{6} + \text{&c.} \leq 0;
\]

and similarly in the case of a minimum,

\[
\frac{d^2y}{dx^2} \frac{h^2}{2} - \frac{d^3y}{dx^3} \frac{h^3}{6} + \text{&c.} \leq 0,
\]

Now, as we are at liberty to take \( h \) as small as we please, we may suppose it so small, that in each series the amount of all the terms after the first shall be incomparably less than that term; then the amount of all the terms in each series will have the same sign as

---

* For, supposing the series to be \( \frac{dy}{dx} + \frac{d^2y}{dx^2} + \frac{d^3y}{dx^3} + \text{&c.} \) let it be put under this form \( A(\frac{dy}{dx} + \frac{d^2y}{dx^2} + \text{&c.}) \) As \( h \) decreases \( p \) remains the same; but the expression \( \frac{dy}{dx} + \frac{d^2y}{dx^2} + \text{&c.} \) decreases, and may be less than anything assignable; therefore, \( p \) may exceed \( h(\frac{dy}{dx} + \frac{d^2y}{dx^2} + \text{&c.}) \) in any ratio of inequality whatever.
its first term, provided that \( \frac{dy}{dx} \), the coefficient of \( h \) in that term, is not \( =0 \), for then the term itself would be \( =0 \).

now this must really be the case, that is, \( \frac{dy}{dx} \) must be \( =0 \); for were it otherwise, \( h \) might be taken so small, that one of each pair of series (A), (B) would be a positive, and the other a negative quantity, and the same would also be true for every smaller value of \( h \). But this would not accord with the nature of a maximum or minimum, which requires, that in the first case, the two series should be both less than \( 0 \); and that, in the second, they should be greater than \( 0 \); therefore, when the function \( y \) is a maximum or minimum, we must have \( \frac{dy}{dx} = 0 \); and then it will follow, that in the former case,

\[
\frac{dy}{dx} = \frac{6y}{d^2x^2} + \frac{6y}{d^2x^2} + \frac{6y}{d^2x^2} + \dots \leq 0,
\]

and in the latter,

\[
\frac{dy}{dx} = \frac{6y}{d^2x^2} + \frac{6y}{d^2x^2} + \frac{6y}{d^2x^2} + \dots > 0.
\]

In all these series, the sign of the first term is the same; therefore, when \( h \) is a very small quantity, so that the amount of all the terms after the first is incomparably less than that term, the amount of all the terms in each pair will have the same sign as they ought, and this will also be true for every smaller value of \( h \). Moreover, as in the case of a maximum, each series must be \( < 0 \), therefore \( \frac{dy}{dx} \), the coefficient of the first term, must be a negative quantity. In the case of a minimum, however, each series is \( > 0 \), and therefore \( \frac{dy}{dx} \) must be positive.

If, however, the substitution of \( a \) for \( x \) in the developments makes not only \( \frac{dy}{dx} = 0 \), but also \( \frac{dy}{dx} = 0 \); then, to satisfy the condition of the maximum, we must have

\[
\frac{dy}{dx} = \frac{6y}{d^2x^2} + \frac{6y}{d^2x^2} + \frac{6y}{d^2x^2} + \dots + 0,
\]

and in the case of the minimum,

\[
\frac{dy}{dx} = \frac{6y}{d^2x^2} + \frac{6y}{d^2x^2} + \frac{6y}{d^2x^2} + \dots - 0.
\]

By pursuing the same train of reasoning as before, it will appear, that these conditions can only be satisfied when we have also \( \frac{dy}{dx} = 0 \); and so on.

63. Upon the whole, it appears that when \( y \) is any function of a single variable quantity \( x \), it is a maximum or minimum, then \( \frac{dy}{dx} = 0 \); and that if the value of \( x \), determined from this equation, make \( \frac{dy}{dx} \) a negative quantity, the function \( y \) is a maximum; but if it be a positive quantity, then \( y \) is a minimum. If, however, this value of \( x \) render \( \frac{dy}{dx} = 0 \); then, unless at the same time it make \( \frac{dy}{dx} = 0 \), the function can neither be a maximum nor a minimum. If we have \( \frac{dy}{dx} = 0 \), the function \( y \) will be a maximum when \( \frac{dy}{dx} \) is negative, and a minimum when this expression is positive; and so on, the first fluxional coefficient which does not vanish, being always of an even order when \( y \) can have a maximum or minimum value.

The correct theory of maxima and minima, was first given by Maclaurin in his Fluxions, Book I. chap. 9.

Example 1. To divide a right line into two such parts, that the rectangle contained by its segments shall be the greatest possible.

Let the whole line be \( a \), and one of its segments \( x \); then the other will be \( a-x \); and the rectangle, \( (a-x)x \) as \( a^2 \). Therefore, we must have \( y=a-x-x^2 \), a maximum; hence, by the general rule,

\[
\frac{dy}{dx} = a-2x = 0.
\]

This equation gives \( x=\frac{a}{2} \). Moreover, since we have \( \frac{dy}{dx} = -2 \), a negative quantity, we infer that the value \( x=\frac{a}{2} \) corresponds to a maximum; which is also easily proved upon other principles.

Ex. 2. To find the fraction that exceeds its cube by the greatest quantity possible.

Let \( x \) be the fraction, then we must give such a value to \( x \), that \( y=x-x^3 \) shall be a maximum. In this case,

\[
\frac{dy}{dx} = 1-3x^2 = 0;
\]

therefore, \( x=\pm\sqrt{\frac{1}{3}} \). And since \( \frac{dy}{dx} = -6x=\mp 6\sqrt{\frac{2}{3}} \), it follows from the rule, that the maximum value of the function corresponds to \( x=\pm\sqrt{\frac{1}{3}} \); but it has also a minimum value corresponding to \( x=\mp\sqrt{\frac{2}{3}} \).

Ex. 3. To determine the greatest rectangle that can be inscribed in a given triangle.

Let \( ABC \) (Fig. 2). Plate CCLV.) be the given triangle, and \( EFGH \) the greatest rectangle that can be inscribed in it. Draw the perpendicular \( AD \) meeting \( EF \) in \( G \). Put \( BC=a \); \( AD=b \); \( EF=x \); and the area of the rectangle \( EFGH = y \). By similar triangles, \( BC:AD = EF:AG \); that is, \( a:b = x:AG \); hence,

\[
AG = \frac{b}{a}x, \quad \text{and} \quad DG = \frac{b}{a} - x = \frac{b(a-x)}{a};\quad \text{and} \quad DG \times EF = \frac{b}{a}(a-x-x^2) = y, \text{therefore,}
\]

\[
\frac{dy}{dx} = \frac{b}{a}(a-2x) = 0;
\]

hence \( a=2x \), and \( x=\frac{a}{4} \). The altitude of the rectangle is therefore half that of the triangle.

64. When the quantity which is to be a maximum or minimum is multiplied or divided by any constant quantity, that quantity may be rejected: Thus we may reject \( \frac{b}{a} \) and make \( y=ax-x^2 \); which will lead to the same result. In general, when a variable function is the greatest or least possible, any constant multiple or
part of that function, also any constant power or root of it, will be the greatest or least possible. In some cases, it may be convenient to remark, that when a quantity increases or decreases, its logarithms increases or decreases.

65. Ex. 4. Of all right angled triangles having the same hypotenuse, find that which has the greatest area.

Let ABC be the triangle (Fig. 3); put the common hypotenuse AC = r; the variable base AB = x; the area = y. Then, because of the elements of geometry, BC = \sqrt{(a^2-x^2)}, we have y = \frac{r^2}{2}\sqrt{(a^2-x^2)} - \frac{r^2}{2}x, and hence the value of x may be found as in the former examples. Or, we may reject the factor \frac{r}{2}, and find x, so that the square of the expression \sqrt{(a^2-x^2)}, may be a maximum (art. 64), so that putting \( y' = \frac{a^2}{2} x - \frac{1}{2} x^2 \), we have
\[
\frac{dy}{dx} = \frac{a^2}{2} - x = 0.
\]
Hence \( x^2 = \frac{a^2}{4} \), from which it appears that the sides about the right angle are equal. In this, as in the preceding example, the nature of the question excludes the supposition of a minimum.

Ex. 5. To determine the dimensions of a cylindric measure, open at the top, which shall contain a given quantity (of liquor, grain, &c.) under the least internal surfaces possible.

Let ABCD be the measure (Fig. 4); put the diameter BC = x, the depth AB = y; the number that expresses the circumference of a circle, of which the diameter is unity, viz. \( \frac{\pi}{2} \); and let c be the content of the cylinder. Then, by geometry, \( \pi x y \) is the circumference of the base, and \( \pi x v \) is the concave surface of the cylinder. Also, the area of the base is \( \pi x^2 \), and the solid content is \( \frac{\pi x^2 y}{2} \); which being made \( \equiv c \), we find \( v = \frac{4c}{\pi x^2} \); this value of v being put in the expression for the concave surface, it becomes \( \frac{4c}{\pi x^2} \), which being denoted by y, we have
\[
\frac{dy}{dx} = \frac{4c}{\pi x^2} - \frac{2x}{\pi} = 0;
\]
\[
\frac{d^2y}{dx^2} = \frac{8c}{\pi x^2} + \frac{\pi}{2}.
\]
From the first of these equations, we get \( x^2 = \frac{4c}{\pi} \), and \( x = \frac{2}{\sqrt{\pi}} \); as this is a positive quantity, the expression we have found for \( x^2 \) corresponds to a minimum value (art. 63). Now, since \( \pi x^2 = \frac{8c}{\pi} \), and \( x^2 v = c \); we have \( \pi x^2 = \frac{8c}{\pi} \), and hence \( x = \frac{2}{\sqrt{\pi}} \); thus it appears that the diameter of the base must be exactly double the depth of the measure; also, that \( x = \frac{1}{2} \sqrt{c} \).

Ex. 6. The flame of a candle is directly over the centre of a circle, the radius of which is 12 inches: what ought to be its height above the plane of the circle, so as to illuminate the circumference the most possible?

Let BC be the candle, (Fig. 5.) C the position of the flame, and A any point in the circumference. By the principles of optics, the intensity of the illumination of the plane at any point will be directly as the sines of the angles of the incident rays, and inversely as the square of the distance from the luminous point: therefore, the effect of the candle to illuminate the plane at A may be expressed by \( \frac{\sin CAB}{CA^2} \). Put \( AB = a; \) and sin. CAB \( = x; \) then, \( CA = \frac{AB \cdot \sin CAB}{\sqrt{(1-x^2)}} \), or \( \sin CAB = \frac{x}{a^2} \); and so, rejecting the constant divisor \( a^2 \), we have \( y = x(1-x^2) = x^2 - x^3 \); Now we have already found (in Ex. 2.), that this function is a maximum, when \( x = \sqrt{3} \); This makes the angle CAB = 59° 16', nearly, and \( AB : BC = 1 : 71 \) nearly; therefore, \( BC = 8.5 \) inches.

Ex. 7. To find the position of the planet Venus in respect of the earth and the sun, when the area of the illuminated part of her disk is a maximum.

In Fig. 6. let S be the Sun, E the Earth, and the circle a b c Venus. Draw V a and V b perpendicular to VS and VE. The illuminated surface of Venus is the hemisphere c a b; but of this, only the part b a is turned towards the Earth, and it appears as a luminous crescent contained between half the circumference of the disk and a semicircle; the breadth of the crescent is the versed sine of the arc a b; but the angles DV a, EV b being equal, the angle a V b is equal to the angle DVE; therefore, the breadth of the crescent is as the versed sine of the angle DVE. Now, by the nature of the figure, the area of the crescent will be to the area of the whole disk, as its breadth to the diameter, (as easily inferred from Conic Sections, Part VII. Prop. 3.), and again, the apparent area of the disk is inversely as the square of the distance of the planet from the Earth: therefore, the apparent illuminated area, as seen from the Earth, will always be directly as the versed sine of the angle DVE, and inversely as the square of EV, and may be expressed by \( \frac{c(1 - \cos EVD)}{EV^2} \), or by \( \frac{c(1 - \cos EVS)}{EV^2} \), c being some constant quantity.

Put SV = a, SE = b, VE = x; then, by trigonometry, cos. SVE = \( \frac{a^2 + x^2 - b^2}{2 ax} \). Let y denote the apparent illuminated disk, then, from what has been shewn, we have
\[
y = \frac{c(a^2 + x^2 - 2ax - b^2)}{2ax},
\]
therefore, taking the fluxions,
\[
\frac{dy}{dx} = \frac{6b^2 - 8ax}{2ax^2},
\]
Hence we have
\[
x^2 + \frac{4a}{x} x^2 \equiv 3(b^2 - a^2),
\]
a quadratic equation, which gives \( x = \sqrt{(3b^2 - a^2)} - 2a \).
If we make \( b = 1000 \), then \( a = 724 \); and hence \( x = 429 \). In the triangle SVE, it will be found that the angle E = 40° nearly. It is when Venus has this position, that she is sometimes seen in the day time. See Astronomy, p. 655.

Ex. 8. To find the position of a straight rod, or beam, when it rests in equilibrio upon a prop, and one end touching an upright wall.

It is a principle in mechanics, that when a body rests in equilibrio, its centre of gravity is either the highest or the lowest possible. By this principle, the theory of maxima et minima may be elegantly applied to the resolution of innumerable problems in statics. In the present example, let EF (Fig. 7.) be the wall, PR Fig. 7.
FLUXIONS.

421

the prop, AB the beam which touches the wall at B, and rests upon the prop at P. Let C be the centre of gravity of the beam. Through P draw the horizontal line DE, and draw CD perpendicular to DE. Put PE = a, CB = b, these are given quantities; also, put PD = x, DC = y: Then, by the principles of mechanics, y must be the greatest possible.

From similar figures, BC : DE :: PC : PD; that is, 
\[ b : a + x :: \sqrt{\left(\frac{a}{x} + y\right)^2} : x; \]
Hence, 
\[ \left(a + x\right)^2\left(x^2 + y^2\right) = b^2 x^2, \]
and taking the fluxions, and dividing by 2 dx,
\[ \left(a + x\right)\left(x^2 + y^2\right) + \left(a + x\right)^2 \left(x + y \frac{dy}{dx}\right) = b^2 x. \]
Because y is a maximum, \( \frac{dy}{dx} = 0 \), therefore this last equation may be abbreviated to
\[ (a + x)\left(x^2 + y^2\right) + x(a + x)^2 = b^2 x. \]
When we have eliminated \( x^2 + y^2 \), by this and the first equation, we get
\[ (a + x)^2 = a b^2. \]
Hence \( x \) is determined.

In this example, as well as in some others, for the sake of brevity, we have assumed the possibility of the quantity \( y \) having a maximum, as it is sufficiently indicated by the nature of the question. For, supposing \( P \) the point of support, to be between, C and the wall, if B, the end of the rod, be carried along a vertical line FE, the line DC=y will manifestly increase to a certain point, and their decrease.

65. In explaining this theory, we have only considered functions of a single variable quantity. When the expression to be a maximum or minimum contains functions of two or more variable quantities, which are independent of one another, the general theory becomes more intricate, and its complete explanation would swell this article beyond the limits we can allow to it. We must therefore refer, on this point, to Euler's Calculus Differentials, Part 2d, Chap. xi.; to Lagrange's Théorie des Fonctions Analytiques, No. 160; and to Lacroix's Traité du Calcul Differenciel, Vol. I., No. 165.

Method of Tangents.

67. Let CPD be any curve referred to an axis AB, (Fig. 8.) and let PQ, PQ' be two consecutive ordinates, and AQ, AQ' the corresponding abscissae, A being the origin of the co-ordinates. Through P, P' draw the secant PPS, meeting the axis in S, and draw PE parallel to the line, meeting P'Q in E. Put the abscissa AQ = x, the ordinate PQ = y, and QQ' (the increment of \( x \)) = h. As \( y \) is a function of \( x \), when \( x \) becomes \( x + h \), by Taylor's theorem (art. 53) \( y \) becomes
\[ y + \frac{dy}{dx} h + \frac{d^2 y}{dx^2} h^2 + \frac{d^3 y}{dx^3} h^3 + &c. \]
but PQ' is the value of \( y \) corresponding to \( x + h \); therefore,
\[ P'Q' = y + \frac{dy}{dx} h + \frac{d^2 y}{dx^2} h^2 \]
and \( P'Q = \frac{dy}{dx} h + \frac{d^2 y}{dx^2} h^2 + &c. \) and
\[ P'E = \frac{dy}{dx} h + \frac{d^2 y}{dx^2} h^2 + &c. \] and \( \frac{P'E}{PE} = \frac{dy}{dx} + \frac{d^2 y}{dx^2} h + &c. \) Now \( \frac{P'E}{PE} \) is the trigonometrical expression for the tangent of the angle \( P'PE \), or \( S \); therefore,
\[ \tan S = \frac{dy}{dx} + \frac{d^2 y}{dx^2} h + \frac{d^3 y}{dx^3} h^2 + &c. \]
Suppose now QQ'=h, the increment of \( x \), to be continually diminished; when Q' comes to Q, the two points of intersection P', P coincide, and the secant P'PS becomes PT, a tangent to the curve at P; and as the angle S becomes then the angle T, and \( h = 0 \), we have
\[ \tan \text{ang} T = \frac{dy}{dx}. \] (1)

The segment TQ of the axis comprehended between PT the tangent, and PQ, the ordinate at the point of contact, is called the subtangent. By trigonometry,
\[ \tan \text{ang} T = \frac{PQ}{TQ}, \] therefore,
\[ \text{subtangent} TQ = \frac{dx}{dy} \] (2)

Hence, in the right angled triangle TPQ, we have
\[ \tan \text{ang PT} = \frac{Q'm}{TQ}, \] therefore, observing that \( PQ = y \), we have by trigonometry, and geometry,
\[ \text{Subnormal} QN = \frac{dy}{dx} y. \] (4)

Normal PN = \( \frac{y}{dx} \sqrt{(dx^2 + dy^2)} \) (5)

68. We shall now apply these formulae to some examples.

Ex. 1. Let the curve be a circle, (Fig. 9.) and let A, Q being the centre of the diameter, be the origin of the co-ordinates; put the radius OA = a; the equation of the curve is \( y^2 = 2 a x - x^2 \). Hence, taking the fluxions, \( y d y = a d x - x d d x \), and, by formula (2) (Art. 67.)
\[ \frac{dx}{dy} y^2 = \frac{y^2}{a - x} = TQ \] the subtangent; therefore, \( OQ : QP : : QP : QT \).

Ex. 2. Suppose the curve a parabola, (Fig. 10.) and fig. 10. that A, the vertex of the axis, is the origin of the co-ordinates. Let a be the parameter of the axis. The equation of the curve (Conic Sections, Sect. VIII.) is \( y^2 = 2 a x \); hence, \( 2 y d y = 2 a d x \), and
\[ \frac{dy}{dx} = \frac{a}{a} = 2 x = TQ \] the subtangent:
\[ \frac{dy}{dx} = \frac{dx}{dy} = \frac{a}{x} = QN \] the subnormal.

Hence it appears that the subtangent is bisected at the vertex; and that the subnormal is half the parameter.

Ex. 3. Let the curve be an ellipse, (Fig. 11.) and fig. 11. let O, the centre, be the origin of the co-ordinates. Let \( a \) denote the half the greater, and \( b \) half the lesser axis; The equation of the curve is \( a^2 y^2 + b^2 x^2 = a^2 b^2 \); (Conic Sections, Sect. VIII.) hence \( a y d y + b x d x = 0 \), and
\[ \frac{dy}{dx} = \frac{a x}{b^2} = \frac{a x - x^2}{x} = TQ \]

The general formula for the subtangent was investigated upon the supposition that the abscissa and subtan-
gent were on the same side of the ordinate: as in the present case the subtangent comes out a negative quantity, we may infer that it and the abscissa are on opposite sides of the ordinate; so that, without regarding position, \( TQ = \frac{a^2 - x^2}{x} \), from which it appears, that the subtangent is independent of the conjugate axis. In the hyperbola, the subtangent may be found by exactly the same process.

Ex. 4. Let the curve be a cycloid, (Fig. 12), of which \( AB \) is the axis, and \( AHB \) the generating circle. Let the origin of the co-ordinates be \( A \), the vertex; and let us suppose that the radius of the generating circle is unity. Put the arc \( AH = v \); then, by the nature of the curve, (see **Epicycloid**), \( x = 1 - \cos v \), \( y = v + \sin v \); therefore,

\[
\frac{dx}{dv} = \sin v, \quad \frac{dy}{dv} = 1 + \cos v
\]

That is, \( \frac{PQ \times AQ}{HQ} = TQ \); therefore, \( QH : QP : QA : QT \). Hence it appears that the tangent \( PT \) is parallel to \( AH \), the chord of the generating circle, as was proved in the article **Epicycloid**.

Ex. 5. In the logarithmic curve, of which the equation is \( y = a^x \), we have \( \frac{dy}{dx} = a^x \ln(a) \), \( dx = y \ln(a) \), therefore,

\[
\frac{dx}{dy} = \frac{1}{\ln(a)} \text{subtangent.}
\]

In this case, the subtangent is a constant quantity.

60. When a curve is expressed by a polar equation, we may first find the equation of the rectangular co-ordinates, as is explained in Curve Lines, art. 21, and then apply the formula; but it will be more convenient to have formula suited to that particular mode of expressing the nature of the curve. Let the centre of the polar co-ordinates be \( A \), the origin of the rectangular co-ordinates, (Fig. 13) and suppose the curve to be defined by an equation between the revolving radius \( PA = r \), and the variable angle \( PAB = v \), which makes with the axis \( AB \). We may now regard the angle \( v \) as the independent variable quantity, and \( AQ = x, PQ = y, \) and \( AP = r \) as functions of that quantity. Put \( t \) for the angle \( PTQ \); then because the angle \( TPA = v - t \), therefore tan. \( TPA = -\frac{y}{x} = -\tan v - \tan t \),

(Arithmetic of Sines, art. 26.) But tan \( v = \frac{PQ}{AQ} = \frac{y}{x} \), and we have found (art. 67), that tan \( t = \frac{dy}{dx} \); therefore,

\[
\tan TPA = \frac{ydv - xdy}{xdv + ydy} = \frac{ydv - xdy}{xdv + ydy}.
\]

Now, by trigonometry,

\[
x = r \cos v, \quad y = r \sin v
\]

therefore, taking the fluxions, (art. 29, and art. 26. Rule D.)

\[
dx = \cos v \cdot dv \quad dx = \cos v \cdot dv
\]
\[
dy = \sin v \cdot dv \quad dy = \sin v \cdot dv
\]

and hence again,

\[
y \cdot dx = r \cos v \cdot \sin v \cdot dv \quad dy = r \cos v \cdot \sin v \cdot dv
\]
\[
xdv = r \cos v \cdot \sin v \cdot dv \quad x \cdot dv = r \cos v \cdot \sin v \cdot dv
\]
\[
dx \cdot dv = r^2 \cos v \cdot \sin v \cdot dv \quad dy \cdot dv = r^2 \cos v \cdot \sin v \cdot dv
\]

Therefore, \( ydx - xdy = r^2 \cdot dv \),

and hence,

\[
\tan TPA = \frac{r^2 dv}{r^2 dr} = \frac{dv}{dr}.
\]

Through \( A \), draw \( AT' \) perpendicular to the polar radius \( AP \) meeting the tangent in \( T' \); and from the point of contact \( P \), draw \( PN \) perpendicular to the tangent, meeting \( TA \) in \( N \). We may now consider \( AT' \) as the subtangent and \( AN \) as the subnormal. And because, in the similar right angled triangles \( T'AP, PAN \),

\[
\tan TPA = \frac{r}{r^2} = \frac{dv}{dr},
\]

therefore, subtangent \( AT' = \frac{dv}{dr} r^2 \).

70. In some curves, the distance between the origin of the co-ordinates and the point in which the tangent meets the axis increases continually, so that when the abscissa is infinite, that distance becomes infinite. In others, even when \( x \) is infinite, the tangent cuts the axis at a finite distance from the origin: it is then an asymptote to the curve. If, from the subtangent \( QT = \frac{dy}{dx} \), (Fig. 8.) the abscissa \( AQ = x \) be subtracted, Fig. 8. the remainder \( \frac{dx}{dy} \cdot x = x \) is the general expression for TA, the distance of the intersection of the tangent and axis from the origin of the co-ordinates. If when \( x \) is infinite this expression is finite, we may conclude that the curve has asymptotes, but if it be infinite, then the curve has no asymptote.

Ex. 1. The equation of the hyperbola (Cosic Sections, Sect. VIII.) is \( a^2 y^2 = b^2 x^2 - a^2 b^2 \), the origin of the co-ordinates being at the centre; in this case, \( a^2 ydy = b^2 x dx \), and

\[
\frac{dx}{dy} = \frac{a^2 y^2 - x^2 - a^2}{x} = \frac{x^2 - a^2}{x} \text{and} \quad \frac{dy}{dx} = \frac{a^2}{x^2}.
\]

When \( x \) is supposed infinite, the expression \( \frac{a^2}{x} \) becomes \( 0 \); hence we infer that the curve has asymptotes, which pass through the centre.

Ex. 2. The equation of the parabola is \( y^2 = ax \), hence

\[
\frac{dy}{dx} = x; \quad \text{when} \ x = \infty, \ \text{this} \ \text{quantity} \ \text{becomes} \ \infty; \ \text{therefore} \ \text{the} \ \text{curve} \ \text{has} \ \text{no} \ \text{asymptote.}
\]

The method of tangents is an important branch of the theory of curve lines. It serves to determine their greatest and least ordinates, (which may also be found by the theory of maxima and minima), and many circumstances relating to their figure; but our limits will not allow us to touch on these. The reader will find them amply detailed in Théorie des Fonctions Analytiques, Lagrange; Traité du Calcul Differentiel, vol. i. Lacroix; A Treatise of Fluxions, Maclaurin; Analyse
Of the Fluxions of the Area and the Arc of a Curve.

71. In any curve, we may consider $x$, one of the co-ordinates, as an independent variable quantity, and then the other, also the area, the arc, and every quantity connected with the curve, may be regarded as functions of that quantity.

Let $C$, hence, $y(x-k'A) = \frac{1}{2}r^2$, therefore

$$\frac{d}{dx} \left\{ f(x) \right\} = \frac{dy}{dx} = \frac{1}{2} \sqrt{1 + \left( \frac{dy}{dx} \right)^2}$$

Hence it appears, that the fluxion of the curvilinear sector $CAP = s$, is half the product of the square of the revolving radius $r$, and the fluxion of the angle it makes with the fixed axis $AC$.

73. Archimedes, and all geometers since his time, have admitted as an axiom, that if two lines of any kind have the same extremities, and their concavities turned both the same way, the shorter of the two is that which is in the space bounded by the other line, and the straight line which joins their common extremities. Hence it follows, that an arc of a curve, which has its concavity turned all one way, is greater than its chord, but less than the sum of two tangents drawn at the extremities of the arc. Proceeding from this principle, we may determine the limits of the ratios of the arc, the chord, and the sum of the two tangents to one another, supposing the arc to be diminished indefinitely, as follows:

In Fig. 16. let $ABD$ be any arc of a curve, $AB = r$, the chord; $AC = b$, and $BC = a$, the tangents at its extremities. By trigonometry, $\sin A$, and $\frac{b}{c} = \sin B$, therefore $\frac{a}{b} = \frac{\sin A}{\sin B}$.

Conceive now the arc $ABD$ to decrease continually, by the point $B$ approaching to $A$; the angles $A$ and $B$ will manifestly both decrease, and they may become less than any assignable angles whatever; therefore $A$, and $B$, both approach continually to 0; and $\sin (A-B)$, and $\cos (A-B)$, approach to 1, which is their common limit. Hence the limit of the ratio of $a + b$ to $c$ is the ratio of 1 to 1, that is, a ratio of equality; and as the arc $ABD$ is always of an intermediate magnitude between $a+b$ and $c$, much more is the limit of the ratio of the arc to the chord, also the limit of its ratio to the sum of the tangents a ratio of equality.

74. In the curve $CDP$, (Fig. 17.) let $PO$, $PQ'$ be Fig. 17. two ordinates perpendicular to the axis $AB$; and suppose that the intermediate ordinates go continually increasing, or else decreasing. Draw the tangents $PP'$, $P'H'$, meeting the ordinates in $H$ and $H'$. The arc $PP'$ is less than one of the two tangents $PH$, $P'H$, but greater than the other; for draw the chord $PP'$, and let the tangents $PH$, $P'H$ meet in $I$, then because, from the nature of the figure, $P'H'$, one of the tangents, must make a greater acute angle with the ordinates than the chord makes with them, it will be less than the chord, and therefore it will be less than the arc. And again, because the acute angle, which the other tangent PH makes with the ordinates, is less than the acute angle made by $P'H'$, the line $HI$ must be greater than $P'I$, and $H'I$ greater than $P'I + P'H'$, and therefore $H'I$ must be greater than the arc $P'I$.

Hence also it is easy to infer, that the limit of the ratio of an arc to its chord is a ratio of equality. For the lines $PH$, $P'H$, are manifestly to one another as the
cosecants of their inclinations to the ordinate PQ, (Trigonometry); but as the point P approaches to P', the inclination of the line P'H approaches to that of PH, and at last the two lines coincide; therefore, the limit of the ratio of PH to P'H is a ratio of equality, and as the chord and arc are of an intermediate magnitude between PH and P'H, the limit of their ratio must also be that of equality.

75. Supposing A to be the origin of the rectangular co-ordinates (Fig. 17.) and C a given point in the curve, let AQ=x, PQ=y, CP=z, and let z be considered as a function of x. Draw PK parallel to the axis; then, because the arc PP', and the line PK, are corresponding increments of z and x, the expression for the fluxional ratio \( \frac{dz}{dx} \) will be equal to the limit to which the fraction \( \frac{PK}{PP'} \) approaches, when QQ=PK, the increment of x, is diminished indefinitely, (art. 23.) Now we have seen, that the arc PP' is of an intermediate magnitude between the lines PH, 1°H, which touch the curve at P and P'; therefore the fraction \( \frac{arc\ PP'}{arc\ PP} \) is always of an intermediate magnitude between these two. \( \frac{PH}{PP} \) and \( \frac{1°H}{PP} \). But we have seen, (art. 74.) that when P' approaches to P, the ratio of P'H to PH approaches to a ratio of equality; therefore the limit of \( \frac{arc\ PP'}{arc\ PP} \) will be \( \frac{PH}{PP} \) and consequently the limit of arc PP' will also be \( \frac{PH}{PK} \). Hence we have \( \frac{dz}{dx} = \frac{PH}{PP} \).

And since, by trigonometry, \( \frac{PH}{PP} \) is the secant of the angle HPK=\( \sqrt{(1+\tan^2 HPK)} \), and by art. 67., formula (1), \( \frac{PH}{PP} = \frac{dy}{dx} \); therefore \( \frac{dz}{dx} = \sqrt{1 + \left( \frac{dy}{dx} \right)^2} \), and hence again,

\[
\frac{dz}{dx} = \sqrt{\left( \frac{dx}{dy} \right)^2 + 1} = \sqrt{x'^2 + y'^2} \quad (1)
\]

From which expression it appears, that the square of the fluxion of the arc, is the sum of the squares of the fluxions of the rectangular co-ordinates.

76. In the case of curves expressed by a polar equation, (Fig. 15.) let A be the given point, about which the radius AP=r revolves; put \( v \) for the variable angle which r makes with AB, a given line by position passing through A; and suppose the curve to be also referred to this line as an axis by rectangular co-ordinates, having their origin at A, so that AQ=x and PQ=y, then

\[
\begin{align*}
x &= r \cos v, \\
y &= r \sin v, \\
dx &= -r \sin v \, dv + \cos v \, dr, \\
y &= r \cos v \, dv + \sin v \, dr, \\

dx &= r \cos v \, dv + \sin v \, dr, \\
dy &= r \sin v \, dv + \cos v \, dr, \\
dx &= r \sin v \, dv + \cos v \, dr, \\
dy &= r \cos v \, dv + \sin v \, dr, \\
dx &= r \sin v \, dv + \cos v \, dr, \\
dy &= r \cos v \, dv + \sin v \, dr, \\
dx &= r \sin v \, dv + \cos v \, dr, \\
dy &= r \cos v \, dv + \sin v \, dr, \\
\end{align*}
\]

Therefore,

\[
\frac{dz}{dx} = \sqrt{\left( \frac{dx}{dy} \right)^2 + 1} = \sqrt{x'^2 + y'^2} \quad (1)
\]

This formula expresses the fluxion of the arc of a curve, by the fluxion of the revolving radius \( r \), and the fluxion of the angle which it makes with the axis AB.

77. We shall now explain another method of defining a curve by a polar equation, which leads to a simple expression for the fluxion of the arc.

Let CPD (Fig. 18.) be the curve, and A a given point in AB, a straight line given by position. Draw a tangent PE at any point P, and AE a perpendicular on the tangent from A; then, if we know the relation between the angle BAE and the perpendicular AE, we can find the value of the perpendicular, corresponding to any given value of the angle; and, as the fluxional calculus gives a general expression for the tangent PE, in terms of the perpendicular and the angle, (as we shall presently show), we can find also the length of the tangent; hence the point P may be found, and as many more points in the curve as we please.

Take another point P' in the curve, and draw a tangent P'E', meeting the former in G; also draw AE' perpendicular to P'E'. Let the angle BAE be denoted by \( u \), the arc CP by \( z \), the perpendicular AE by \( p \), and EI, the part of the tangent between the perpendicular and point of contact, by \( t \); then, supposing the angle \( u \) to be the independent variable quantity, \( p, t, \) and \( z \), may be regarded as functions of \( u \). Put \( k \) for the angle EAH, the increment of \( u \), and \( p' \) for AE'; also let \( P'E' \), the new values of \( p \) and \( t \), corresponding to \( u+h \), the new value of \( u \).

From the disposition of the lines in the figure, we have

\[
E'P' = EP - E'G + GP' = (EH + HG - GP) = PG + GP - EH - (HG - GE) \quad \text{and dividing by the arc} \ h,
\]

\[
\frac{E'P' - EP}{h} = \frac{PG + GP'}{h} - \frac{EH}{h} - \frac{HG - GE}{h} = \frac{PG + GP'}{h} - \frac{EH}{h}.
\]

Now, by trigonometry, \( EH = p \tan h \); and, because the triangles AEA, GE'H are similar, \( E'G = GH \cdot \cos h \); therefore, by substituting, we get

\[
\frac{t'}{h} = \frac{PG + GP'}{h} - \frac{p}{h} - \frac{1}{h} \cdot \cos h \cdot HG.
\]

Suppose now, \( h \) to be diminished indefinitely, by which \( P' \) will approach to \( P \); we have then, limit of \( \frac{t'}{h} = \frac{d}{du} (art. 23) \), and limit of \( \frac{PG + GP'}{h} = \frac{dz}{du} (art. 73.) \) and because limit \( \frac{\tan h}{h} = 1 \) (art. 73.)

Therefore, limit \( \frac{\tan h}{h} = p \). And since \( \cos h = 1 - \frac{h^2}{2} + \frac{h^4}{24} + \ldots \) (art. 53.), therefore \( \frac{1}{\cos h} = \frac{h}{2} - \frac{h^3}{24} + \ldots \) and limit \( \frac{1}{\cos h} \cdot HG = 0 \).

Hence, upon the whole,

\[
\frac{d t}{du} = \frac{dz}{du} - p \frac{d u}{du}.
\]

And \( dz - d t = d (z - t) = p \, d u \).

In the figure from which this formula has been investigated, the arc and tangent proceed in the same direction from the point of contact: If they had proceeded in contrary directions, the formula would have been

\[
d(z - t) = p \, d u.
\]

To express \( t \) by means of \( p \) and \( u \), we have

\[
d(z - t) = p \, d u.
\]
of Fluxions. 425.

$AE' - AE = AH + HE' - AE$ 

Now, $HE' = E'G \times \tan \cdot h$, and $AE = AH \times \cos \cdot h$; therefore, after substituting and dividing by $h$,

$$\frac{p - p'}{h} = \tan \cdot h \cdot E'G + \frac{1 - \cos \cdot h}{h} \cdot AH.$$  

Suppose now $h$ to decrease continually, then we have

$$\lim \frac{p - p'}{h} = \frac{dp}{du}; \text{ limit } \frac{\tan \cdot h}{h} = 1; \text{ limit } E'G = t; \text{ limit } \frac{1 - \cos \cdot h}{h} = 0; \text{ therefore}$$

$$\frac{dp}{du} = t.$$  

This formula corresponds to the case in which the tangent and curve proceed in the same direction from the point of contact; when they proceed in opposite directions, it will be $-\frac{dp}{du} = t$, so that, including both cases in one formula, we have

$$t = \pm \frac{dp}{du}. \quad (4)$$

This formula gives the tangent in terms of $p$ and $u$, when the relation of $p$ to $u$ is known. Hence, also, it follows, that $dt = \pm \frac{d^2p}{du^2}$; so that, in addition to the formulæ investigated in art. 75. and art. 76. for the fluxions of an arc, from what has been found in this article, we have these two,

$$d(z \equiv t) = pdu, \quad (5)$$

$$dz = pdudp = \frac{d^2p}{du^2}. \quad (4)$$

We do not recollect to have seen these in any work on fluxions: they deserve attention on account of some elegant applications of which they are susceptible.

The application of the formulæ investigated in this Section, will be found in the Second Part of this article, when we come to the Quadrature and Rectification of Curves.

Of the Fluxions of Solids and Surfaces of Revolution.

78. A solid of revolution is that which is generated by the rotation of a curve of any kind about its axis, just as a sphere is generated by the rotation of a semicircle about its diameter, or a right cone, by the rotation of a right angled triangle about one of the sides containing the right angle. The curve surface of a solid, generated in this manner, is a surface of revolution. Figures of this kind are also called Conoids. They all agree in this property, that any section of the solid by a plane perpendicular to the axis of revolution, is a circle.

79. Let $PA$ be a solid of revolution, (Fig. 19.), $AB$ its axis, $P'E$ and $P'E'$ two sections perpendicular to the axis, such, that these, and any intermediate sections, shall form a series that goes on increasing or decreasing: Let $P'F$ and $P'F'$ be the diameters of the sections, and $QQ'$ the segment of the axis between them. Construct the cylinders $P'E$ and $P'E'$ of $H$, and $P'E$ and $P'E'$ having the common altitude $QQ'$. Put $AQ = x$, $PQ = y$, the solid $AP'E$ $p = x$, the number $3.1416$ (the ratio of the circumference to the diameter of a circle) $= \pi$; also put $h$ for $QQ'$, the increment of $x$; $k$ for $PH$, the increment of $y$; and $l$ for the conoidal solid $P'E'$ $p = PE', p'$, the increment of $s$. Then, by the elements of geometry,
and again, substituting the fluxional ratios instead of the limiting ratios of the increments, and regarding \(v\) and \(z\) as functions of \(x\),
\[
\frac{dv}{dx} = 2y \frac{dz}{dx}
\]
Hence, \(dv = 2y \, dz\).

Thus it appears, that the fluxion of a surface of revolution is equal to the fluxion of the arc of the generating curve, multiplied by the general expression for a section of the surface, by a plane perpendicular to its axis.

**On the Contact of Curves, and Circle of Curvature.**

81. Let two curves, \(CD\), \(ed\) have the same axis \(AB\), (Fig. 21) and the same point \(A\) for the origin of their co-ordinates; let \(y = f(x)\) and \(z = f'(x)\) be their respective ordinates, corresponding to the common abscissa \(x = AQ\); and let their equations be \(y = f(x)\), and \(z = f'(x)\). Let us also suppose, that when \(x\) becomes \(x + h\), \(y\) becomes \(y'\), and \(z\) becomes \(z'\); then, by Taylor's theorem, (art. 52.)
\[
y' = y + \frac{dy}{dx} h + \frac{d^2 y}{dx^2} \frac{h^2}{2} + \&c.
\]
\[
z' = z + \frac{dz}{dx} h + \frac{d^2 z}{dx^2} \frac{h^2}{2} + \&c.
\]
Suppose now the curves to have a common point \(P\), at which \(y = \varphi\); then if \(\frac{dy}{dx} = \frac{dv}{dz}\); the nature of their contact at that point is such, that no third curve having the same common point, can pass between them, unless it has a like property; that is, supposing \(u\) to be the ordinate of the third curve, corresponding to the common abscissa \(x\), and \(u'\) its value, corresponding to \(x + h\), so that
\[
u' = u + \frac{du}{dx} h + \frac{d^2 u}{dx^2} \frac{h^2}{2} + \&c.
\]

This curve, leaving \(P\), cannot pass between the other two, unless \(\frac{du}{dx} = \frac{dv}{dz}\). For let us suppose it possible; then because in general, \(P'P' = y' - \varphi = y - \varphi + \left(\frac{dy}{dx} - \frac{du}{dx}\right) h + \left(\frac{d^2 y}{dx^2} - \frac{d^2 u}{dx^2}\right) \frac{h^2}{2} + \&c\),

and by hypothesis, \(y = \varphi\), also \(\frac{dy}{dx} = \frac{dv}{dz}\), therefore,
\[
y' - \varphi = \left(\frac{d^2 y}{dx^2} - \frac{d^2 u}{dx^2}\right) \frac{h^2}{2} + \left(\frac{d^2 y}{dx^2} - \frac{d^2 u}{dx^2}\right) \frac{h^2}{2} + \&c\).
\]

This is the general expression for the excess of \(P'P'\), the ordinate of the first curve above \(P'P'\), the ordinate of the second. In like manner, the difference of the ordinates of the first and third curve, or
\[
y' - u' = y - u + \left(\frac{dy}{dx} - \frac{du}{dx}\right) h + \&c
\]
or, because \(y = u\),
\[
y' - u' = \left(\frac{dy}{dx} - \frac{du}{dx}\right) h + \left(\frac{d^2 y}{dx^2} - \frac{d^2 u}{dx^2}\right) \frac{h^2}{2} + \&c
\]
Now, because this third curve is supposed to pass between the other two, (that is, between \(P\) and \(P'\)), we must have, to a certain extent on each side of \(P\), \(y' - v' = y - u'\), that is,
\[
\left(\frac{dy}{dx} - \frac{du}{dx}\right) h + \left(\frac{d^2 y}{dx^2} - \frac{d^2 u}{dx^2}\right) \frac{h^2}{2} + \&c.
\]

and hence, dividing by \(h^2\),
\[
\frac{d^2 y}{dx^2} - \frac{d^2 u}{dx^2} \frac{h}{2} + \frac{d^2 y}{dx^2} - \frac{d^2 u}{dx^2} \frac{h}{2} + \&c.
\]
This ought to be true for every value of \(h\) that is less than \(QQ\'). But \(h\) being supposed to decrease, the first of these two expressions may become less than anything assignable, because \(h\) enters into all its terms, while the second approaches to the limit \(\frac{dy}{dx} - \frac{du}{dx}\). Now this conclusion is incompatible with the first expression, being greater than the second, unless \(\frac{dy}{dx} - \frac{du}{dx} = 0\), that is,
\[
\frac{dy}{dx} = \frac{du}{dx}.
\]

82. Again; if in the two curves, whose equations are \(y = f(x)\), \(z = f'(x)\), and which have a common ordinate \(y = \varphi\), and which have also \(\frac{dy}{dx} = \frac{dv}{dz}\); no other curve can pass; unless the fluxion of its ordinate \(u\) be equal to the fluxion of \(v\) or of \(\varphi\), so that \(\frac{du}{dx} = \frac{dv}{dz}\).

Now this cannot hold true, unless \(\frac{dy}{dx} - \frac{du}{dx} = 0\), and also \(\frac{d^2 y}{dx^2} - \frac{d^2 u}{dx^2} = 0\); for, were this not the case, \(h\) might be taken of such a magnitude, that the whole amount of the first of these two expressions should be less than either the first or second term of the other expression, in any ratio of inequality whatever, instead of being greater than the whole expression; because of its terms involving higher powers of \(h\). If, however, \(\frac{dy}{dx} = \frac{du}{dx}\), and \(\frac{d^2 y}{dx^2} = \frac{d^2 u}{dx^2}\), then, that the third curve may pass between the other two, it is only requisite that
\[
\left(\frac{d^2 y}{dx^2} - \frac{d^2 u}{dx^2}\right) \frac{h}{2} + \left(\frac{d^2 y}{dx^2} - \frac{d^2 u}{dx^2}\right) \frac{h}{2} + \&c.
\]
which is certainly possible.

83. In general, if there be any curve whatever, and another given curve, have a common point with it, which requires that their ordinates corresponding to the same abscissa should be equal; then, if the first
fluxions of these ordinates for the same abscissa are also equal, it will be impossible that any other curve drawn through that point can pass between them, unless the first fluxion of its ordinate corresponding to the same abscissa is equal to the first fluxions of their ordinates: And if, besides the first fluxions of these ordinates, their second fluxions, for the same abscissa, are also equal; it will be impossible that any other curve which passes through the common point can go between them, unless the first and second fluxions of its ordinate are respectively equal to the first and second fluxions of the ordinate common to the two curves, and so on of the higher orders of fluxions.

In fact, the two curves only coincide in the points in which their ordinates are equal; and the equality of the different orders of fluxions merely shews, that no other curve, in which the same equality has not place, can pass between them. This is the view that ought to be taken of the contact of curves; and it agrees with the doctrine of the ancient geometers, as far as they entered into this theory; for they considered a straight line as a tangent to a curve, when no other straight line could be drawn between them from the point in which they meet each other. (Elements of Euclid, Book III. Prop. 16.) The application of Algebra to Geometry has led to other views, particularly that in which a secant is considered as becoming a tangent, when two of its intersections coincide. As this manner of considering the subject is simple, and sufficiently strict, we have employed it in treating of the theory of tangents. (Art. 67.)

84. As an illustration of this theory, let us consider the nature of the contact of any curve CPD, (Fig. 8,) and a straight line TP, supposing A to be the origin of the common abscissa. Let AQ = x, and APQ (taken as any ordinate of the curve CPD) = y, also APQ (taken as any ordinate of the straight line TP) = v; put TA = a, and tangent of angle T = t; then the equation to the straight line PT is evidently v = t (x + a) = t x + at; hence, as a and t are constant, we have, for every point in the straight line TP, dv = t dx, and \( \frac{dv}{dx} = t \). As besides the straight line and curve having a common point at P, which is expressed by the equation v = y, we further suppose the nature of the contact to be such, that \( \frac{dv}{dx} = \frac{dy}{dx} \); it follows that \( \frac{dv}{dx} = t \). This result agrees with what we found in art. 67., formula (1), and thence the subtangent TP may be determined, as was there explained.

The line PT being thus determined, it is impossible that any straight line can be drawn from P, that shall pass between PT and the curve: For, if possible, let the line PS pass between them, and meet the axis in S. Put AS = a', tangent of angle S = t'; P(\( \text{Q} \) considered as an ordinate of PS) = u; then the equation of the line PS is \( u = t'(a' + x) \), and hence \( \frac{du}{dx} = t' \). Now, in order that the line PS may pass between the curve and the straight line PT, it ought to satisfy the condition \( \frac{du}{dx} = \frac{dy}{dx} \) (art. 81.): hence we must have \( t' = t \), that is the tangent of the angles PTA, and PSA must be equal, which can only happen when the lines PT, PS coincide; Thus the line PT is a tangent according to the strictest acceptation of the term.

85. Let us now consider the contact of a circle and any curve; let the circle EPF meet the curve CPD in the point P, (Fig. 22.) Suppose that AB is their common axis, and A the origin of the common abscissa, A Q = x; then put y = PQ, considered as an ordinate of the curve CPD; and v = P Q, considered as an ordinate of the circle EPF. Let H be the centre of the circle; draw HI, HK perpendicular to PQ and AB. Put r = PH, p = AK, q = HK, so that p and q are the co-ordinates of the centre of the circle, then HI = p — x, and PI = v — q; and since, from the nature of the circle, PH = PI + HI; therefore

\[
(p - x)^2 + (v - q)^2 = r^2. \tag{1}
\]

First let us suppose that the kind of contact is such as is indicated by the equality of the first fluxions of the ordinates; so that \( \frac{dy}{dx} = \frac{dv}{dx} \). The preceding equation, in which p, q, and r are to be considered as constant quantities, and v as a function of x, gives us

\[
-2(p - x) \cdot dx + 2(v - q) \cdot dv = 0, \quad \text{and hence}
\]

\[
\frac{dv}{dx} = \frac{p - x}{v - q}. \tag{2}
\]

Now \( p = x \), \( HI = HQ \), \( PQ = QN \); therefore, \( \frac{dv}{dx} = \frac{QN}{v} = \frac{v}{QN} \); and since by hypothesis, \( v = y \) and \( \frac{dv}{dx} = \frac{dy}{dx} \); therefore \( \frac{dy}{dx} = \frac{QN}{v} = \frac{v}{QN} \). But this expression for QN is identical with that given in art. 67. for the normal of a curve; therefore QN is the subnormal, and consequently the centres of all circles, which have the kind of contact we are considering, are in a normal to the curve at the common point P.

When a circle has this kind of contact with a curve, no other circle of an equal radius, but whose centre is out of the normal, can pass between it and the curve. For, supposing it possible, let p' and q' be the co-ordinates of the centre of this other circle, and u its ordinate to the abscissa x; then, in like manner, as in the former circle, we have found

\[ \frac{dv}{dx} = \frac{p - x}{v - q} = \frac{p - x}{v - q} \]

in the other circle, we must similarly have

\[ \frac{dv}{dx} = \frac{p' - x}{v' - q} = \frac{p' - x}{v' - q} \]

And as upon the hypothesis that this last circle passes between the other circle and the curve, we ought to have

\[ \frac{dv}{dx} = \frac{dy}{dx} = \frac{dv}{dx} \] (art. 81.) therefore

\[ \frac{dv}{dx} = \frac{p - x}{p' - x} \]

This equation gives \( p' = p \), from which it follows, that \( q' = q \), so that the two circles have their centres at the same point, and therefore are identical.

The kind of contact which we have been considering, which is analogous to the contact of a straight line and curve, may be called a contact of the first order.

86. Let us next suppose the curve and circle to have a closer degree of contact, so that not only \( v = y \), and \( \frac{dv}{dx} = \frac{dy}{dx} \) but also \( \frac{d^2y}{dx^2} = \frac{d^2v}{dx^2} \).

From the second equation of last article we find
FLUXIONS.

87. The centre of the circle of curvature being different for different points of a curve, there is a certain line LM, belonging to the curve, which is the locus of all the centres. The quantities p, q are manifestly coordinates to any point II of this locus, and its nature is expressed by the two equations (B), (C). In any given curve, the values of y, d y and d x may be all expressed by x and d x, and these being substituted in the expressions for p and q, they will involve only the indeterminate quantity x, which may be eliminated by means of the two equations, and the result will be an equation involving only p, q and known quantities, which will be an equation of the locus of the centre of the circle of curvature.

88. Formula (A) of last article serves to find the radius of curvature, when the nature of the curve is indicated by the relation of the rectangular co-ordinates: But let us now suppose, that its nature is defined by an equation expressing the relation between AB = p, a perpendicular from any given point in the axis BA upon a tangent at P and the angle BAE = u, which that perpendicular makes with the axis (Fig. 18.) Fig. 18. Draw the normal PN, and let x and y be the rectangular co-ordinates of the point P. The angle at N = u is manifestly the compliment of the angle which the tangent makes with the axis; hence \( \frac{dy}{dx} = \cot u \) (formula (1), art. 67.) and taking the fluxions considering u and y as functions of x, \( \frac{dy}{dx} = \frac{-u}{\sin u} = -du \cdot \cosec^2 u \).

(art. 34.) but \( \cosec^2 u = 1 + \cot^2 u \) \( \therefore \frac{dy}{dx} = \frac{dx^2 + dy^2}{dx^2} \) \( \therefore \frac{dx}{dy} \frac{dy}{dx} = \frac{-du}{dx^2} \) (putting z for the curve and observing that \( \frac{dy}{dx} = \frac{dx^2 + dy^2}{dx^2} \), art. 75.) and since by formula (A), last art.

\[ r = \frac{(dx^2 + dy^2)}{dx^2} \]

\[ \therefore \quad \frac{dx}{dy} = -\frac{dz}{du} \]

\[ \therefore \quad r = -\frac{dz}{du} \]

Here we have a very simple expression for the radius of curvature, from which it appears to be equal to the fluxion of the arc divided by the fluxion of the angle which the normal makes with the axis.

And as we have found (art. 77.) that \( dz = p \frac{dy}{dx} + \frac{dy}{dx} \frac{d^2x}{du^2} \), therefore

\[ r = p + \frac{dy}{dx} \frac{d^2x}{du^2} \]

This is the expression for r which we proposed to investigate.

89. We shall now show the application of the formula we have found for the radius of curvature.

Ex. 1. Let the curve be a parabola (Fig. 23.) and let A the vertex of the axis AB, be the origin of the co-ordinates \( AQ = x \), and \( AQ = y \). Let a be the parameter of the axis, then, by the nature of the curve,

\[ y = ax \], hence \( y = a \frac{1}{2} x^2 \), and \( dy = a \frac{1}{2} dx \) and \( d^2y = \frac{1}{4} a dx^2 \). Therefore, \( dx^2 + dy^2 = dx^2 + \frac{a}{4} dx^2 = \frac{1}{4} dx^2 (4x + a) \); and by formula (A), art. 86.

\[ \frac{dx}{dy} = \frac{(4x + a)}{2 \sqrt{a}} \]

If \( x = 0 \), then \( r = \frac{1}{2} a \); this is the radius of curvature at the vertex.

As an example of the application of the third formula for the radius of curvature, let us again take the para-
bola, and let F be the focus, and FE a perpendicular to the tangent PE. Draw a straight line from E to A, the vertex of the axis; then AE is a tangent at the vertex, (Conic Sections, Sect. IV. Prop. 14. cor. 1,) and therefore FAE is a right angled triangle. Hence, putting FE = p, and the angle AFE = \( \xi \), and observing that AF = \( \frac{1}{2} \) parameter = \( \frac{1}{2} a \), we have for the equation of the curve

\[
p = \frac{a}{4 \cos \xi}.
\]

And taking the fluxions, by art. 20, and art. 26, observing that \( p \) is a function of \( \xi \),

\[
\frac{dp}{du} = \frac{a \sin \xi}{4 \cos^3 \xi}, \quad \frac{d^2p}{du^2} = \frac{(\cos^2 \xi - 2 \sin^2 \xi)a}{4 \cos^3 \xi}.
\]

Therefore, by formula (A), art. 88,

\[
r = p^\frac{3}{2} = \frac{2 \{ \cos^2 \xi + \sin^2 \xi \} a}{4 \cos^3 \xi} = \frac{1}{2} a \cos \xi,
\]

\[
d^2r = \frac{d^2p}{du^2} \frac{1}{dr} = \frac{2 \cos \xi}{4 \cos^3 \xi} = \frac{\cos \xi}{2 \cos^2 \xi}.
\]

and hence we have also \( r = \frac{a}{2} \cos \xi \).

Ex. 2. Let the curve be any one of the conic sections. If the origin of the co-ordinates be taken at one extremity of the principal axis, their nature may be expressed by the equation

\[
y^\frac{1}{2} = mx + nx^2.
\]

Hence we find,

\[
dy = \frac{(m+2nx)}{2y} dx,
\]

\[
dx^2 + dy^2 = \left\{ 4y^\frac{1}{2} + (m+2nx)^2 \right\} dx^2
\]

\[
= \frac{4 (m + x + nx^2) + (m + 2nx)^2}{4y^\frac{1}{2}} dx^2.
\]

\[
d^2y = \frac{2ny dx - (m + 2nx) dy}{2y'} dx^2
\]

\[
= \frac{4ny^2 - (m + 2nx)^2}{4y^\frac{1}{2}} dx^2.
\]

Hence, from formula (A), we get

\[
r = \frac{\left\{ 4y^\frac{1}{2} + (m + 2nx)^2 \right\}}{8ny - 2(m + 2nx)^2}.
\]

and substituting for \( y^\frac{1}{2} \) its value,

\[
r = \frac{4(m + x + nx^2) + (m + 2nx)^2}{2m^2}.
\]

By giving to \( m \) and \( n \) the values that belong to the different curves, (Conic Sections, Sect. VIII,) this formula will give the radius of curvature in each case.

90. It appears from what has been shown in this section, that the contacts of curve lines may be arranged according to different orders. The degree of contact, in which the ordinates, and also their first fluxions, are equal, (art. 81,) may be called a contact of the first order; and when in addition to these, the second fluxions are equal, (art. 82,) it is a contact of the second order; and so on.

There are curves which, with a given curve, admit only of contacts of a certain order. A straight line, for instance, is only capable of a contact of the first order. A curve may have a contact of the first, and also of the second order, but none higher; and a curve, whose equation is \( y = a + bx + cx^2 + dx^3 \), is also capable of a contact of the third order; and so on. The degree of contact of which a curve is capable, depends upon the number of constant quantities to be determined. These may be called the elements of contact. A contact of the first order requires two constant quantities; a contact of the second requires three; and so of the higher orders.

In an analytical point of view, the contact of a straight line, or of a circle with a curve, is not more interesting than the contact of any other curve, unless on account of these curves being more elementary. The circle of curvature is, however, interesting, because of the simple geometrical expression it gives for the measure of a deflecting force. (Principia, lib. i. prop. vi. See also Physical Astronomy, chap. i.)

91. The first formula which we have given for the radius of curvature, (art. 86,) has been investigated upon the hypothesis, that the curve is concave towards the axis. In this case, \( \frac{d^2y}{dx^2} \) is a negative quantity; and hence the sign of the expression for \( r \) is negative. If the curve had been convex towards the axis, then the sign of \( \frac{d^2y}{dx^2} \), and of the expression for \( r \), would have been positive. Upon the first hypothesis, \( r \) comes out a positive quantity in the applications of the formula, as in the examples we have given; but when the curve is convex towards the axis, it has a negative value.

Of the Evolutes of Curves.

92. Let LHM be a curve of any kind. (Fig. 24,) and let us suppose that a thread, fastened to the curve at some point beyond M, is drawn tight, and applied upon it, so as to have the position CLOM; that this may be done, the curve may be conceived to be the common section of a plane, and some solid rising a little above it, round which the thread is wound. Suppose now, that while the thread is kept tight, it is gradually unwound from the curve. While the portion between L and H is unwinding, its extremity \( P \) will describe upon the plane some line CP, and the process of unwinding being continued, a curve CPD will be generated, the nature of which will depend on the mode of its generation, and the properties of the other curve LHM.

The curve along which the thread is wrapped, is called the Evolute of the curve, generated by the extremity of the thread; and, on the other hand, the latter curve is called the Involute of the former. Our present object is to show, how the evolute of any proposed curve CPD, may be found.

93. From the manner in which a curve is generated from its evolute, we may immediately draw these three conclusions:

1. The portion of the thread PH, which is disengaged from the evolute, is a tangent to it at H.
2. The straight line PH, is equal to the arc CH of the evolute.
3. Any tangent to the evolute, is a normal to the curve. In fact, any point H of the evolute may be considered as a momentary centre; and the line HP as the radius of a circle which the point P is describing, when the point of contact of the tangent and curve is at H. It is from this last property, that we propose to deduce a solution of our problem.

Let AB be a common axis to the two curves, and let the normal PH produced meet the axis in N. Let P'N' be another position of the normal, meeting the
FLUXIONS.

430

Direct
Method.

former in O. Draw PG, PG, tangents to the curve,
meeting in G (these lines will be perpendicular to PO,
PO) and join GO. Put x for the arc CP, y for the
angle which the normal makes with the axis at N, and
r for PH, the portion of the thread evolved from the
arc CH. By trigonometry, \( r = \frac{OG \times \sin \theta}{PG} \); and
\[ PG + \sin \theta = OG. \]

Conceive now the point P\textsuperscript{1} to approach P, then O will
approach H, and the line OG will approach in mag-
itude to HP\textsuperscript{1} = r, which will be its limit; also the frac-
tion to which OG is equal, will approach to angle POP\textsuperscript{1}
(art. 73.) Hence, remarking that the arc PP\textsuperscript{1} and
the angle POP\textsuperscript{1} are the corresponding increments of \( x \) and
\( y \), and passing to the limits, we have (art. 23;)
\[ \frac{dy}{dx} = r. \]

But this value of \( r \) is the very expression which we
have found for the radius of curvature, (formula \( A^3 \),
art. 88.) Therefore, \( r \) is the radius of curvature, at \( P\textsuperscript{1} \); and
because PH is a normal to the curve, \( H \) is the cen-
tre of the circle of curvature; and the evolute LOM is
the locus of the centre of that circle. Hence, if \( \Delta Q=x \),
and \( \Delta Q=y \), be the co-ordinates of \( P \), any point in the
curve CP\textsuperscript{1}D, and \( AK=p \), and \( KH=q \), the co-ordinates
of \( H \), the corresponding point in the evolute, by
art. 86. formulae \( B \), \( C \), its equation will be,
\[ p = x - \frac{dy}{dx} \cdot \frac{dx}{dy} + \frac{dy}{dy} \cdot \frac{dy}{dy} = y + \frac{dy}{dx} \cdot \frac{dy}{dy}. \]

For example, if the curve CP\textsuperscript{1} be a parabola, then
putting \( a \) for the parameter, in this case \( y^2 = ax\); and
\[ \frac{dy}{dx} = \frac{a}{2y}, \quad \frac{dy}{dy} = \frac{a}{2y^2} \]
and
\[ p = 3x + \frac{a}{4}, \quad q = - \frac{a}{4}. \]

As \( q \) comes out negative, the parabolic arc and its
evolute lie on opposite sides of the axis. Moreover, since
\[ 2 \frac{xy}{6} = ax, \quad \text{and} \quad \left( \frac{a}{4} \right)^2 y^2 = ax, \]
we easily find,
\[ 27a^2 q^2 = 16(p - \frac{a}{4})^3. \]

This equation belongs to the semicubical parabola.

94. The theory of evolutes, one of the most elegant
speculations in geometry, is due to Huygens, who hand-
led it at considerable length in his Horologium Oscilla-
torium. We have seen, that it is closely connected with
the theory of contacts; and indeed, it is usual to define the
circle of curvature, from the property of its radius being
equal to the evolving radius. We have, however, after
Lagrange, followed a method more strictly analytical.
We might have deduced the properties of evolutes, from
the formula in art. 86, for the centre and radius of cur-
vature; but as a more elementary mode, we have been
chosen to prove the identity of the evolute, and the locus
of the centre of the circle of curvature, by employing the
principle which originally led to the theory.

As the radius of curvature is always equal to the arc
of the evolute, from which it has been unwrapped; and
2 as in geometrical curves, that radius is in every case an
algebraic expression, of a finite number of terms, and the
evolute also a geometrical curve; it follows, that to
every geometrical curve whatever, there is a correspond-
ing geometrical curve which may be rectified; that is,
to which a straight line can be found equal. This was
proved by Huygens; and it shewed, that Descartes was
wrong in supposing, that it was impossible to find a
straight line equal to a curve.

For the evolutes of the cycloid and epicycloid, see
our article Epicycloid.

Of changing the Independent Variable Quantity.

95. We have all along supposed \( x \) to vary in any
manner whatever, and estimated the change that takes
place in \( y \), any function of \( x \), by referring it to the
change in the magnitude of \( x \), which, on that account,
was the independent variable quantity. It is sometimes
convenient, however, to vary the hypothesis, and pass
from the supposition of \( y \) being a function of \( x \), to that
of \( x \) being a function of \( y \).

The form of a fluxional expression depends very much
upon the quantity that is regarded as the independent
variable. Thus in art. 67, we have found, that if \( s \) de-
note the sub-tangent of a curve, and \( x \) and \( y \) the co-
dinates, then \( s = \frac{dx}{dy} \); and this is true, whether \( y \) be con-
sidered as a function of \( x \), or \( x \) as a function of \( y \). From
this expression, by regarding \( x \) and \( y \) as functions of \( x \),
(since \( dx \) is constant,) we have
\[ s = \frac{d}{dy} \left( \frac{dy}{dx} \cdot y \right) = \frac{dy}{dx} - \frac{dy}{dx} \cdot \frac{dy}{dx}. \]

If, however, we reckon \( x \) and \( y \) as functions of \( y \), then
as \( dy \) must be now constant, we have \( ds = dx + \frac{dy}{dx} \cdot \frac{dy}{dx} \)
an expression quite different from the former. We are
now to investigate general rules, by which, in such cases,
the one expression may be deduced from the other.

96. Let \( y = f(x) \), and let us suppose, that when \( x \)
becomes \( x + \delta x \), then \( y \) becomes \( y + \delta y \). By Taylor's theo-
rem,
\[ k = \frac{dy}{dx} + \frac{dy}{dx} \cdot \frac{dx}{dy} + \frac{dy}{dx} \cdot \frac{dx}{dy} \cdot \frac{dx}{dy} + \ldots \]

(1.)

But let us now suppose, that from the equation
\( y = f(x) \), we deduce \( x = \tilde{f}(y) \), so that \( x \) is a function of
\( y \); then similarly,
\[ h = \frac{dx}{dy} + \frac{dx}{dy} \cdot \frac{dy}{dx} + \frac{dx}{dy} \cdot \frac{dy}{dx} \cdot \frac{dy}{dx} + \ldots \]

(2.)

Let the value of \( k \), as expressed by the first equation,
be substituted in the second; and, with a view to a
bride, let us put
\[ y' \text{ for } \frac{dy}{dx}, \quad y'' \text{ for } \frac{dy}{dy}, \quad \text{etc., also } x' \text{ for } \frac{dx}{dy}, \]
and we have
\[ h = \frac{x'}{y''} + \frac{x'}{y''} \cdot \frac{y'}{y''} + \frac{x'}{y''} \cdot \frac{y'}{y''} \cdot \frac{y'}{y''} + \ldots \]

\[ + \frac{x'}{y''} \cdot \frac{y'}{y''} + \frac{x'}{y''} \cdot \frac{y'}{y''} \cdot \frac{y'}{y''} + \ldots \]

(3.)

\[ + \frac{x'}{y''} \cdot \frac{y'}{y''} + \frac{x'}{y''} \cdot \frac{y'}{y''} \cdot \frac{y'}{y''} + \ldots \]

Hence, by actually involving the series to the 2d, the
3d powers, \&c. and bringing together like powers of \( h \),
we find
\[ 0 = (x' y'' - 1) h + (x' y'' + x'' y') \]
Now, as \( h \) is altogether independent of \( x' \), \( x'' \), &c., the coefficients of its powers must be each \( =0 \), hence
\[
\begin{align*}
x' y' - 1 & = 0, \\
x' y'' + x'' y' & = 0, \\
x' y''' + 3 x' y' + x''' y & = 0, &c.
\end{align*}
\]
from which equations, we get
\[
\begin{align*}
y' &= \frac{1}{x^2}, \\
y'' &= -\frac{x'}{x^3}, \\
y''' &= \frac{3x''}{x^5} - \frac{x'}{x^2}, \\
y^{(4)} &= \frac{15x^2}{x^7} + \frac{10x x''}{x^5} - \frac{x'}{x^2} &; &c.
\end{align*}
\]
and, on the other hand,
\[
\begin{align*}
x' &= \frac{1}{y}, \\
x'' &= -\frac{y'}{y^2}, \\
x''' &= \frac{3y''}{y^3} - \frac{y'}{y} \\
x^{(4)} &= \frac{15y^2}{y^7} + \frac{10y y''}{y^5} - \frac{y'}{y} , &c.
\end{align*}
\]
97. In finding the first formula for the radius of curvature, viz. \( r = -\frac{(d x^2 + d y^2)^{\frac{1}{2}}}{d x d y} \), we have regarded \( y \) as the independent variable quantity. Now, to show the use of the formulae investigated in last article, let it be required to transform it into another, in which \( y \) shall be the independent variable quantity. In the first place, employing the notation of last article,
\[
r = -\frac{1 + \frac{d x}{d y} \frac{d y}{d x}}{\frac{d y}{d x}} \cdot \frac{d y}{d x} = \frac{1 + \frac{d y}{d x}}{\frac{d y}{d x}}
\]
The second of these expressions is got from the other, by substituting \( \frac{d x}{d y} \) for \( x' \), and \( \frac{d y}{d x} \) for \( x'' \).

98. Sometimes it is necessary to consider both \( x \) and \( y \) (a function of \( x \)) as functions of some third quantity \( t \); and in this view of the matter, neither the fluxions of \( x \) nor \( y \) can be considered as constant. For example, in mechanics, we may consider \( x \) and \( y \) the co-ordinates of the path of a projectile, as functions of \( t \), the time of the motion.

Let us suppose, that when \( t \) becomes \( t + i \), then \( x \) becomes \( x + h \), and \( y \) becomes \( y + k \); and to abridge, let us denote
\[
\begin{align*}
dx &= dx, & \text{by } x', x'', &c.
\end{align*}
\]
\[
\begin{align*}
dt &= dx, & \text{by } x', x'', &c.
\end{align*}
\]
\[
\begin{align*}
dy &= dy, & \text{by } y', y'', &c.
\end{align*}
\]
\[
\begin{align*}
dt &= dy, & \text{by } (y'), (y''), &c.
\end{align*}
\]
Then, by Taylor's theorem,
\[
\begin{align*}
y = f(x) & \text{ gives } k = (y') h + (y'') \frac{h^2}{2} & & (1.) \\
y = F(t) & \text{ gives } k = y' i + y'' \frac{i^2}{2} & & (2.) \\
z = \phi(t) & \text{ gives } h = x' i + x'' \frac{i^2}{2} & & (3.)
\end{align*}
\]
As the increments \( h, k, i \) are all generated together, in consequence of a change in the value of \( t \), these three equations must all hold true at once. Therefore, by substituting the value of \( h \), as given by the third equation in the first, and then putting the two values of \( k \) equal to each other, we get
\[
\begin{align*}
y'(i) + y'' \frac{i^2}{2} \frac{h^2}{2} + & c. \quad (y') \left\{ x' i + x'' \frac{i^2}{2} + & c. \right. \\
+ \frac{(y'')}{2} \left\{ x' i + x'' \frac{i^2}{2} + & c. \right. \\
= y' i + y'' \frac{i^2}{2} + & c.
\end{align*}
\]

Hence, by finding the second power, &c. of the series, and putting the co-efficients of the powers of \( i=0 \), we find
\[
\begin{align*}
x'(y) &= y', \\
x''(y') &= x' y'' + x'' y' = y'', &c.
\end{align*}
\]
therefore, \( y' = \frac{y''}{x'}, \quad y'' = \frac{y'''}{x'} \), &c.

99. Let us again take the formula for the radius of curvature, as an example, which, when expressed in conformity to the notation of last article, will be
\[
r = -\frac{1 + (y')^2}{(y')^2} \cdot \frac{d x}{d t} = \frac{1 + (y')^2}{(y')^2} \cdot \frac{d x}{d t}.
\]
Their values, the formula becomes \( \frac{(x'^2 + y'^2)^{\frac{1}{2}}}{x'' y' - y' x''} \), and reverting to the usual notation, (putting \( \frac{d x}{d t} \) for \( x' \), \( \frac{d y}{d t} \) for \( y' \), \( \frac{d x}{d t} \) for \( x'' \), and \( \frac{d y}{d t} \) for \( y'' \)), we find
\[
r = -\frac{(d x^2 + d y^2)^{\frac{1}{2}}}{d x dy - d y dx}.
\]
Here the fluxions are supposed to be taken relatively to a quantity \( t \), which does not indeed appear in the formula, but nevertheless it must be kept in view.

Of the Fluxions of Functions, which contain two Independent Variable Quantities.

100. We have hitherto considered only functions of a single variable quantity; and this is the most common case; but a function may involve two or more variable quantities, which are quite independent of each other. In geometry, if we suppose any point on the surface of a sphere, to be referred to three planes perpendicular to each other, which pass through its centre, and put \( x, y, z \), for the co-ordinates of that point, and \( a \) for the radius; the equation of the surface is \( x^2 + y^2 + z^2 = a^2 \). (Curve Lines.) Here each of the quantities \( x, y, z \) may be considered as a function of the other two, which may vary independently of one another.

Let \( u \) be any function whatever of two independent variable quantities \( x, y \); or, following the notation of art. 45, let \( u = f(x, y) \); and let \( x \) and \( y \) change their values, so that \( x \) becomes \( x + h \), and \( y \) becomes \( y + k \), \( x \) and \( y \), however, being supposed quite independent of one another. By the change in the value of \( x, z \) becomes \( f(x + h, y) \); and again, in consequence of \( y \) also changing its value, it becomes \( f(x + h, y + k) \). Now, if we first develop \( f(x + h, y) \), supposing \( x \) variable, and \( y \) constant, and then substitute in that partial development \( y + k \) for \( y \), we shall evidently have the complete development of \( (x + h, y + k) \). Or we may reverse
in the development of \( f(x + h, y) \), we get
\[
\begin{align*}
  f(x + h, y) & = f(x, y) + \frac{du}{dx} h + \frac{du}{dy} dy \frac{dh}{dx} + \frac{d^2 u}{dx^2} \frac{d^2 h}{dx^2} + \frac{d^3 u}{dx^3} \frac{d^3 h}{dx^3} + \cdots \nonumber \\
  & + \frac{du}{dy} k + \frac{du}{d^2 y} \frac{dk}{dx} + \frac{d^2 u}{dy^2} \frac{d^2 k}{dx^2} + \frac{d^3 u}{dy^3} \frac{d^3 k}{dx^3} + \cdots 
\end{align*}
\]

This is the complete development of the new value of the function \( u \).

101. According to the other method, supposing \( x \) to remain the same, and \( y \) to become \( y + k \), the corresponding value of \( u \) will be \( f(x, y + k) \)
\[
\begin{align*}
  u + \frac{du}{dx} h + \frac{du}{dy} dy \frac{dh}{dx} + \frac{d^2 u}{dx^2} \frac{d^2 h}{dx^2} + \frac{d^3 u}{dx^3} \frac{d^3 h}{dx^3} + \cdots 
  & + \frac{du}{dy} k + \frac{du}{d^2 y} \frac{dk}{dx} + \frac{d^2 u}{dy^2} \frac{d^2 k}{dx^2} + \frac{d^3 u}{dy^3} \frac{d^3 k}{dx^3} + \cdots 
\end{align*}
\]
Here \( x \) enters into the functions \( u, \frac{du}{dy}, \&c. \) as a constant quantity; but suppose now, that \( x \) changes its value, and becomes \( x + h \), then \( u \) will become
\[
\begin{align*}
  u + \frac{du}{dx} h + \frac{du}{dy} dy \frac{dh}{dx} + \frac{d^2 u}{dx^2} \frac{d^2 h}{dx^2} + \frac{d^3 u}{dx^3} \frac{d^3 h}{dx^3} + \cdots 
  & + \frac{du}{dy} k + \frac{du}{d^2 y} \frac{dk}{dx} + \frac{d^2 u}{dy^2} \frac{d^2 k}{dx^2} + \frac{d^3 u}{dy^3} \frac{d^3 k}{dx^3} + \cdots 
\end{align*}
\]
Also, (employing the same mode of notation as in the other development), \( \frac{du}{dy} \) will become
\[
\begin{align*}
  \frac{du}{dy} + \frac{d^2 u}{d^2 y} \frac{d^2 h}{dx^2} + \frac{d^3 u}{d^3 y} \frac{d^3 h}{dx^3} + \cdots 
\end{align*}
\]
and \( \frac{d^2 u}{d^3 y} \) will change to
\[
\begin{align*}
  \frac{d^2 u}{d^3 y} + \frac{d^3 u}{d^4 y} \frac{dh}{dx^4} + \frac{d^4 u}{d^5 y} \frac{d^2 h}{dx^2} + \frac{d^5 u}{d^6 y} \frac{d^3 h}{dx^3} + \cdots 
\end{align*}
\]
and so on for \( \frac{d^3 u}{d^4 y}, \&c. \) These new values of \( u, \frac{du}{dy}, \&c. \) being substituted in the development of \( f(x, y + k) \), we have \( f(x + h, y + k) \)
\[
\begin{align*}
  f(x + h, y + k) & = f(x, y) + \frac{du}{dx} h + \frac{du}{dy} dy \frac{dh}{dx} + \frac{d^2 u}{dx^2} \frac{d^2 h}{dx^2} + \frac{d^3 u}{dx^3} \frac{d^3 h}{dx^3} + \cdots 
  & + \frac{du}{dy} k + \frac{du}{d^2 y} \frac{dk}{dx} + \frac{d^2 u}{dy^2} \frac{d^2 k}{dx^2} + \frac{d^3 u}{dy^3} \frac{d^3 k}{dx^3} + \cdots 
\end{align*}
\]
This also is the complete development of the function \( u \).

102. If we compare, in these two developments, the terms which contain the same powers of \( h \) and \( k \), we shall find this series of equations,
\[
\begin{align*}
  \frac{d^3 u}{d^2 y} \frac{dh}{dx} & = \frac{d^4 u}{d^3 y} \frac{d^2 h}{dx^2} \\
  \frac{d^3 u}{d^2 y} \frac{d^2 h}{dx^2} & = \frac{d^4 u}{d^3 y} \frac{d^3 h}{dx^3} + \cdots \nonumber \\
  \frac{d^3 u}{d^2 y} \frac{d^3 h}{dx^3} & = \frac{d^4 u}{d^3 y} \frac{d^4 h}{dx^4} + \cdots \nonumber \\
\end{align*}
\]
and in general
\[
\begin{align*}
  \frac{d^3 u}{d^2 y} \frac{dh}{dx} & = \frac{d^4 u}{d^3 y} \frac{d^2 h}{dx^2} \\
  \frac{d^4 u}{d^3 y} \frac{d^2 h}{dx^2} & = \frac{d^5 u}{d^4 y} \frac{d^3 h}{dx^3} + \cdots \nonumber \\
  \frac{d^5 u}{d^4 y} \frac{d^3 h}{dx^3} & = \frac{d^6 u}{d^5 y} \frac{d^4 h}{dx^4} + \cdots \nonumber \\
\end{align*}
\]
The first of these equations shows, that the fluxional coefficient of the second order of a function, containing two variable quantities, taken first relatively to the one, and then relatively to the other, is the very same, in whatever order we proceed in finding the fluxions. This is an important theorem in the calculus. To exemplify this property, let \( n = x^{m-1} y^n \); then, taking the fluxion in respect of \( x \), we find
\[
\frac{du}{dx} = m x^{m-1} y^n; \\
\frac{dy}{dx} = n x^{m-1} y^{n-1}
\]
By proceeding in the contrary order, we find
\[
\frac{du}{dy} = n x^{m-1} y^{n-1}; \\
\frac{dx}{dy} = m x^{m-1} y^n, 
\]
the same result as before.

The other equations given above are merely consequences of the first.

103. As, by the transition of a single variable quantity from one state of magnitude to another, there originates from any function of that quantity a series of other functions, which are denominated its fluxional coefficients, (Art. 23. and 41.); a function of two independent variable quantities must have an analogous property. If we compare the development of a function of a single variable quantity (Art. 59.) with that of a function of two independent variable quantities (Art. 100. and 101.), we see immediately wherein that analogy consists. In the former case, when \( x \) becomes \( x + h \), \( u \) any function of \( x \), becomes \( u + \frac{du}{dx} x h + \frac{d^2 u}{dx^2} h^2 \) + &c.; and in the latter, \( u \) being a function of the independent quantities \( x \) and \( y \), when \( x \) becomes \( x + h \), and \( y \) becomes \( y + k \); then \( u \) becomes \( u + \frac{du}{dx} x h + \frac{d^2 u}{dx^2} h^2 + \frac{du}{dy} y k + \frac{d^2 u}{dy^2} k^2 \); &c. As in the former case, the coefficient of the simple power of the increment \( h \) is the fluxional coefficient of the function; in the latter, the coefficients of the simple powers of the two increments \( h \) and \( k \), may be regarded as the fluxional coefficients of the function: So that, while in a function of a single variable quantity, there is only one fluxional coefficient of the first order; in a function of two independent variable quantities there are two, one \( \frac{du}{dx} \), which is relative to \( x \); and another \( \frac{du}{dy} \), relative to \( y \).

Moreover, as when \( u \) is a function of a single variable quantity, the fluxion of \( u \) is indicated by multiplying its fluxional coefficient by \( dx \), (the symbol for the fluxion of \( x \)) so that the fluxion of the function may be expressed thus \( \frac{du}{dx} dx \); in the case of \( u \), a function of two independent variable quantities, there will be two fluxions connected with the function, one derived from the variable quantity \( x \), which will be expressed \( \frac{du}{dx} dx \), and the other from \( y \), which must in like manner be expressed by \( \frac{du}{dy} dy \). These are called the partial fluxions of the function; and, in the language of the differential calculus, the partial differentials, also, by some, the partial differences. The sum of the partial fluxions, viz. \( \frac{du}{dx} dx + \frac{du}{dy} dy \) is the whole fluxion of \( u \) considered as a function of \( x \) and \( y \).

When \( u \) is a function of \( x \) only, instead of \( \frac{du}{dx} dx \), it is usual to write simply \( du \), because, when there is only one variable quantity, the symbol \( du \) can have but one meaning; but when there are two variable quantities, it is necessary to indicate which part of the whole fluxion results from each; which is conveniently done by writing the fluxional coefficients thus, \( \left( \frac{du}{dx} \right) \times \left( \frac{du}{dy} \right) \); as was done by Euler, or more simply thus \( \frac{du}{dx} dy \), as is now the common practice.

104. As examples of functions of two independent variable quantities, 1. Let \( u = x + y \); then \( \frac{du}{dx} = x, \) and \( \frac{du}{dy} = y \); therefore \( \frac{du}{dx} dx = x d x + y d y \).

2. Let \( u = xy \); then \( \frac{du}{dx} = y, \) and \( \frac{du}{dy} = x \); therefore \( \frac{du}{dx} dx = x d y + y d x \).

3. Let \( u = \frac{x}{y} \); then \( \frac{du}{dx} = \frac{1}{y}, \) and \( \frac{du}{dy} = -\frac{x}{y^2} \); hence, \( \frac{du}{dx} dx = -\frac{x}{y^2} dy \).

In these examples, we have evidently got the same results as if \( x \) and \( y \) had been functions of some third quantity \( t \), (Art. 29, and 30.) Indeed this ought to be the case, seeing that the fluxion of \( u \) cannot be affected by the circumstance of \( y \) being a function of \( x \), unless the particular form of the function be assigned.

105. From the first fluxion of \( u \), a function of the independent variable quantities \( x \) and \( y \), we find its second fluxion thus; because \( \frac{du}{dx} = \frac{du}{dx} dx + \frac{du}{dy} dy \), therefore \( \frac{d^2 u}{dx^2} = \frac{d^2 u}{dx^2} dx^2 + \frac{d^2 u}{dy^2} dy^2 \); &c. Employing still the same notation, \( \frac{d^2 u}{dx^2} dx^2 + \frac{d^2 u}{dy^2} dy^2 \); hence, \( \frac{du}{dx} dx = \frac{du}{dx} dx + \frac{du}{dy} dy \), and \( \frac{du}{dy} dy \), here \( dx \) and \( dy \) are considered as constant.

Therefore, observing that \( \frac{d^2 u}{dx^2} dx^2 = \frac{d^2 u}{dy^2} dy^2 \) (Art. 102.), we have
\[
\frac{d^2 u}{dx^2} = \frac{d^2 u}{dx^2} dx^2 + \frac{d^2 u}{dy^2} dy^2 + \frac{d^2 u}{dy^2} dy^2 + \frac{d^2 u}{dy^2} dy^2.
\]
Thus we see, that the second fluxion of the function \( u \) is composed of three partial fluxions of the second order. The third, and higher fluxions of \( u \), may be found in the same manner.

106. From functions which contain two independent variable quantities, we might proceed to such as contain three. Supposing \( u \) to be a function of three independent variable quantities \( x, y, z \), it will have three partial fluxional coefficients, one relative to \( x \), which may be expressed by the symbol \( \frac{du}{dx} \); another relative to \( y \), which will be \( \frac{du}{dy} \); and a third relative to \( z \), which will be \( \frac{du}{dz} \). Thus there are three partial fluxions,
where \( \frac{du}{dx} + \frac{dy}{dy} + \frac{dz}{dz} \) is the complete fluxion of \( u \). Our limits, however, will not permit us to enter farther into this branch of the subject; besides, it is easy to extend what has been already shewn, to functions of any number of quantities.

**Application of Infinitesimals to Fluxions.**

107. The celebrated Leibnitz founded his theory of the differential calculus upon the doctrine of infinitely little quantities. To this method it has been objected, that the notion of infinitely small quantity is too vague to form the foundation of a mathematical theory, and on this account it has been laid aside by late writers, in establishing the principles of the calculus. It must be confessed, however, that this view of the subject gives readily all the rules for the calculus, and affords a great facility in its applications to geometry and mechanics, particularly in questions of an intricate nature. On this account it is valuable, and, besides, we can always verify the results by more rigorous methods.

108. Leibnitz supposed that variable quantities were augmented by infinitely small increments, which might: be neglected in respect of finite quantities, but which admitted of being compared among themselves. He therefore assumed, that two magnitudes which only differed by an indefinitely small quantity, might be taken the one for the other. The infinitely small increment of \( x \) was denoted by the symbol \( dx \), that of \( y \) by \( dy \), and so on. And it followed immediately from his principle, that in the developments of the increments of a function, all the powers of \( dx \) and \( dy \) that were higher than the first might be neglected. Thus, to find the differential or fluxion of \( x^2 y \); having developed the product \( (x + dx)(y + dy) = x^2 y + xdy + ydx + dx dy \), and substituting for the primitive function \( x \), \( y \), he rejected the term \( dx \) \( dy \), as infinitely little in respect of the two others, and thus got \( dx \), \( dy \), \( 2x dx \) \( y + dy \). In effect, since \( 1: dx :: dy: dx dy \), if we regard \( dx \) as infinitely less than any finite quantity represented by 1, then \( dx \) \( dy \) must be infinitely less than \( dy \) or \( dx \). If \( x = y \), then \( dx = x^2 \). By substituting now \( x^2 \) instead of \( y \), and \( 2x dx \) instead of \( dy \), in the formula \( dx \) \( dy \) \( 2x dx + ydx + dy \), we get \( dx = 2x dx \). In this way, the fluxion of \( x^2 \) may be found.

With regard to fluxions of the higher orders, his theory required that fluxions, or differentials of the second order, should be considered as infinitely little in respect to those of the first order; and therefore as homogeneous with the squares of these last. Hence, to find the second and higher differentials, it was only necessary to consider the differentials as new variable quantities, which had themselves differentials of the next higher order, and to reject from the result all the terms which were of an order superior to that one.

109. Let \( x \) and \( y \) be the co-ordinates of a curve, and \( x \) an arc between the top of the ordinate and some determine point in the curve. Suppose now \( x \) to be augmented by the infinitely little line \( dx \); then, corresponding to this, \( y \) will be augmented by \( dy \), and \( z \) by \( dz \). As this last quantity is indefinitely little, it may be taken as a straight line, which, when produced, will be a tangent to the curve. The three indefinitely little lines, or differentials, \( dx \), \( dy \), \( dz \), form the sides of a right-angled triangle, from which it is easy to deduce the tangent, and every thing relating to the curve.

Thus, \( \frac{dy}{dx} \) will manifestly be the trigonometrical tangent of the angle which a tangent to the curve makes with the axis, and consequently \( \frac{dz}{dy} \) will be the subtangent.

Also, \( y dx \) will be the infinitely little increment, or differential of the area; and, from the nature of a right-angled triangle, we have \( \sqrt{(dx^2 + dy^2)} = dz \), which is the formula for the differential of the arc.

110. Although Leibnitz's view of the subject led to correct results, he did not seize the true spirit of his method. He ought to have given a better reason for rejecting certain quantities, than that of their being indefinitely small, when compared with others which he retained. The truth was, they ought to have been rejected, in order to make the results correct. On this subject, a small tract by Carnot, entitled, *Reflections sur la Méthaphysique du Calcul Infinitesimal*, may be consulted.

**SECTION III.**

**Of the Inverse Method of Fluxions.**

111. The Inverse Method of Fluxions, called also the *Integral Calculus*, treats in general of the manner of finding the fluent of any proposed fluxion; or it teaches how to find fluents, whose fluxions shall have to each other any assigned relation. The general problem to be resolved, is far more difficult than in the direct method. In this last, it is always possible to find the relation of the fluxions, when that of the variable quantities themselves is known; but to determine on the contrary, the relation of the variable quantities from that of their fluxions, is, in many cases, a problem that requires the utmost resources of analysis to give even an approximation to the solution. This arises from the nature of the problem not admitting of general rules. All that can be done, is to compare any proposed fluxion with such fluxions as are derived from known fluents, by the direct method; and if they have the same form, we may conclude that the fluents, or at least their variable parts, are functions of the same form.

As in the direct method, all quantities are reduced, by proper transformations, to a certain number of elementary functions; so in the inverse method, we must endeavour to transform complex fluential expressions into others more simple, so as to reduce them, if possible, to some fluxion, whose fluent is known.

112. We have employed the letter \( d \) as a symbol to indicate the fluxion of any fluent. To denote the fluent of any fluxion, we shall now employ the character \( \int \), the initial letter of the word *sum*, which has been adopted generally by foreign, and partially by British mathematicians. Accordingly, by \( \int x^2 \) \( dx \), the fluent of the expression \( x^2 \) \( dx \) is meant. What we have called a fluent is sometimes denominated by British mathematicians, and always by foreigners, the *Integral*; and to integrate a fluxion, or differential, has the same meaning as to find its fluent. The process by which the integral is found, is called Integration.

**Fundamental Rules.**

113. We have found (Art. 27. and 28.) that in a function consisting of several terms, such as are con-
FLUXIONS.

435

Again, put 

\[ y = \frac{1}{3}(3x^4 + 7) + 1.\]

Therefore, by a proper adaptation of its constant factor: thus,

\[ \int \frac{5}{3} \cdot \frac{12 \cdot 12.3x^4 + 7}{12} + 1.\]

\[
\int 12 (3x^4 + 7) + 1.\]

\[ = \frac{5}{12} (3x^4 + 7) + 1.\]

IV. We have found, (Art. 29.) that \( u \) and \( t \) being any functions of a variable quantity, \( d \) \( t \) \( = u \) \( t \) \( + d \) \( u \), therefore,

\[ u \ t = \int d \ t + \int d \ u \]

and \( \int u \ d \ t = u \ t - \int d \ u \).

This manner of expressing a fluent is of great importance: writers on the differential calculus call it the method of integrating by parts. As an example, let the fluent be \( l. (x) \) \( d \) \( x \); then, putting \( d \ t = d \ x \), and \( u = l. (x) \),

so that \( d \ u = \frac{du}{dx} \), we have

\[ \int l. (x) \ d \ x = l. (x) \ dx \]

The rule indicated by the formula has the advantage of making the fluent depend upon another, which, by analytical address, may frequently be more easily obtained.

V. From rule (D), art. 26, if the radius of a circle be unity, we have

\[ \int \frac{dz}{\sqrt{(1 - z^2)}} = \text{arc. (sin.} = z\right) + c, \]

\[ \int \frac{dz}{\sqrt{(1 - z^2)}} = \text{arc. (cos.} = z\right) + c. \]

By these expressions are meant the arc, of which the sine and cosine are \( z \). Again, from art. 35,

\[ \int \frac{dz}{1 + z^2} = \arctan(z) + c. \]

We may also suppose the radius \( = r \), and we shall have

\[ \int \frac{r \ d z}{\sqrt{(r^2 - z^2)}} = \arcsin(z) + c. \]

To find the fluent of \( \frac{m \ d z}{a + b \ z^2} \), we put it under this form,

\[ \frac{m}{a} \cdot \frac{dz}{1 + \frac{b \ z^2}{a}} \]

by making \( \frac{b \ z^2}{a} = t \). Therefore, \( \frac{m}{\sqrt{(a \ b)}} \) \( \arctan(t) \)

is the fluent sought, supposing the radius unity, and hence

\[ \int \frac{m \ d z}{a + b \ z^2} = \frac{m}{\sqrt{(a \ b)}} \cdot \arctan \left( \frac{b}{a} \right) + c. \]

In like manner we find,

\[ \int \frac{m \ d z}{\sqrt{(a^2 - b \ z^2)}} = \frac{m}{\sqrt{b}} \cdot \arcsin \left( \frac{z}{a} \right) + c. \]

The direct method furnishes other rules, which will be noticed in the sequel.

**Decomposition of Rational Fractions.**

115. Let it be proposed to resolve the fraction \( \frac{k \ x + l}{(x - a)(x - b)} \) into two others, of which it shall be the sum. With a little attention it will appear, that the fractions sought may have the form \( \frac{A}{x - a} \) and \( \frac{B}{x - b} \), \( A \) and \( B \) being indeterminate coefficients, which are in-
FLUXIONS.

In the theory of equations, (ALGEBRA) if $a, b$ be the roots of the equation $x^2 - x - 2 = 0$, then $x^2 - x - 2 = (x - a)(x - b)$. The equation gives $x = a + 2$ and $x = -1$; therefore $x^2 - x - 2 = (x - 2)(x + 1)$ so that we must assume

$$\frac{2 - 4x}{x^2 - x - 2} = \frac{A}{x - 2} + \frac{B}{x + 1}. $$

Hence we find $A = -2 = B$, and the proposed fraction

$$\frac{2 - 4x}{x^2 - x - 2} = \frac{2}{x + 1}. $$

**Ex. 2.** In like manner for the fraction $\frac{1}{a^2 - x^2}$

$$\frac{1}{a^2 - x^2} = \frac{A}{a + x} + \frac{B}{a - x}, $$

we have $1 = A a + a x (B + C) + x^2 (C - A - B)$; which gives $1 = A a$, $B + C = 0$, $C - A - B = 0$; hence $A = \frac{1}{a^2}$, $B = -\frac{1}{2a^2} C = \frac{1}{2a^2}$ thus $\frac{1}{x(a^2 - x^2)} = \frac{1}{a^2 x} - \frac{1}{2a^2 (a + x)} + \frac{1}{2a^2 (a - x)}$.

**Case II.** When the denominator $V$ has unequal and imaginary factors of the first degree, which, when multiplied two and two, produce real factors of the second, so that

$$V = (x^2 + p x + q)(x^2 + p' x + q') \ldots \times S, $$

we may suppose

$$U = A x + B, \quad \frac{C x + D}{x^2 + p x + q} + \frac{E x + F}{x^2 + p' x + q'} \ldots + \frac{P}{S}. $$

**Ex. 4.** Suppose

$$(1 + x)(1 + x^2) = \frac{A}{1 + x} + \frac{B x + C}{1 + x^2}, $$

In this example, $A = \frac{1}{2}$, $B = C = -\frac{1}{2}$.

**Ex. 5.** In like manner, assuming that $\frac{1}{x - 1} = \frac{A}{x} + \frac{B x + C}{x + 1}$, we have $A = C = -B = \frac{1}{2}$.

**Case III.** If $V$ has real and equal factors, so that $V = (x - a)^n S$, we may assume

$$U = A x^{n-1} + B x^{n-2} + \ldots + P, $$

$$V = \frac{A x^{n-1} + B x^{n-2} + \ldots + \frac{T}{x - a} + \frac{P}{S}}{(x - a)^n S}, $$

but it is better to put

**Ex. 6.** Thus for the fraction $\frac{x^2 + x + 2}{x(x - 1)(x + 1)}$, although it may be decomposed into $\frac{A}{x} + \frac{B x + C}{(x - 1)^2} +$...
In the fraction \( \frac{1}{a^2 - x^2} \), \( U = 1 \), \( V = a^2 - x^2 \); therefore \( \frac{dV}{dx} = -2a \); when \( x = a \), \( U \) becomes \( u = 1 \), and \( \frac{dV}{dx} \) becomes \( \frac{1}{a^2 - a^2} = \frac{1}{2a} \) the other is found by making \( x = -a \).

(2.) Next, let us consider the case in which \( U = \frac{A}{V} \)

\[ \frac{(x - a)^n + (x - a)^{n-1} + \ldots + x - a + S}{(x^2 + px + q)^n} \]

Let both members of the equation be multiplied by \( (x - a)^n \), then, observing that \( V = (x - a)^n \) and putting \( U \) under \( \frac{A}{V} \), we have

\[ K = \frac{A}{V} = B(x - a) + C(x - a)^2 + \ldots \]

Now, make \( x = a \), and put \( u \) and \( x \) to denote as before, and have \( A = \frac{u}{S} \); and since

\[ K = \frac{A}{V} = B(x - a) + C(x - a)^2 + \ldots \]

the first member \( K = A \) must be divisible by \( x - a \); it will therefore have the form \( K(x - a) \); hence, \( K = B(x - a) + \ldots \) 

Suppose now \( x = a \), and that then \( K \) becomes \( k _0 \) then we have \( B = k_0 \), and so on.

Or we may employ the fluxional calculus; for since

\[ K = \frac{A}{V} = B(x - a) + C(x - a)^2 + \ldots \]

by taking the fluxions,

\[ \frac{dK}{dx} = B + 2 C(x - a) + 3 D(x - a)^2 + \ldots \]

Put \( k, k', \ldots \) for the values of \( K \), \( \frac{dK}{dx} \), \( \frac{d^2K}{dx^2} \)&c. respectively, in the particular case of \( x = a \); then making that hypothesis, we find

\[ A = k, B = k', C = \frac{k}{2}, D = \frac{k}{2}, \ldots \]

Resuming example 6, of art. 116, we assume

\[ \frac{x^2 + x^2 + x^2}{x^2 - 2x^3 + x} = \frac{A}{x^2 + B + P} \]

Hence

\[ \frac{x^2 + x^2 + x^2}{x(x^2 - 1)} = A + B(x + 1) + \frac{P}{S(x+1)^2} \]

Making now \( x = 1 \), we find \( A = \frac{1}{2}, B = \frac{1}{2} \).

(3.) Let the equation be

\[ U = \frac{Ax + B}{V} \]

then \( U = \frac{A(x + B)S + P(x^2 + q + 2x + q)\ldots}{x^2 + px + q + S^2} \)

If we substitute for \( x \) one of the imaginary roots of the equation \( x^2 + px + q = 0 \), \( P \) will disappear, and the result will contain two kinds of terms, one real, and the other imaginary. We must now put the real quantities on each side of the equation equal to one another, and all the imaginary quantities: thus two equations

\[ \frac{dV}{dx} = \frac{dS}{dx} (x - a) + S; \quad \text{supposing now} \ x = a \]

then, putting \( v' \) for the value of \( \frac{dV}{dx} \) when \( a \) is substitu-
will be obtained, by which \( A \) and \( B \) may be determined. Let the fraction be

\[
\frac{x}{(x-1)(x^2+1)} = \frac{\Lambda x + B}{x^3 + x + 1} + \frac{P}{S},
\]

hence \( x = (\Lambda x + B)(x - 1) + P(x^2 + x + 1). \) Now \( x^3 + x + 1 = 0 \) gives \( x = \frac{-1}{\Lambda} \sqrt{-3}, \) therefore, by substituting in this last equation, it becomes

\[-\frac{1}{\Lambda} \sqrt{-3} = \frac{1}{\Lambda} + A \sqrt{-3} + B \] \( \) \( -\frac{1}{\Lambda} \sqrt{-3} = \frac{1}{\Lambda} + A \sqrt{-3} + B \]

Hence, putting the real and the imaginary parts separately equal, and dividing the latter by \( \frac{1}{\Lambda} \sqrt{-3} = \), we find

\[
\frac{1}{\Lambda} = -B, \quad \frac{1}{\Lambda} = -A + \frac{B}{B};
\]

therefore \( -A = \frac{B}{B} = \frac{1}{\Lambda} \).

(4.) Let us consider the fraction, when \( \frac{U}{V} = \frac{A x + B}{(x^2 + px + q)} + \frac{A x' + B'}{(x^2 + p'x + q')} + \frac{P}{S}, \)

Let both sides of the equation be multiplied by \( (x^2 + px + q)' \), and observing that \( V = (x^2 + p x + q)'S, \) let \( K = \frac{1}{V} \), and we have

\[
K = \frac{A x + B}{(x^2 + px + q)} (x^2 + p x + q) + &c.
\]

This case is compounded of the two preceding, and must be treated in the same manner. In the first place, we substitute for \( x' \) one of the roots of the equation \( x^2 + px + q = 0, \) by which the equation is reduced to \( K = \frac{A x + B}{(x^2 + px + q)} . \) The real and imaginary quantities are now to be made separately equal, as in last case; and hence two equations are got, by which \( A \) and \( B \) are determined.

By taking the fluxions of both sides of the equation, we find

\[
\frac{dK}{dx} = \frac{A + (A x + B')(2x + p)}{(x^2 + px + q)};
\]

here we omit all the terms in which \( x^2 + px + q \) is a factor. By substituting, in this expression, the imaginary value of \( x \) in the equation \( x^2 + px + q = 0, \) and putting the real and imaginary terms on each side equal, two equations are found, by which \( A' \) and \( B' \) are determined.

For example, let the fraction be

\[
\frac{x^3 - 2 x^2 + x - 3}{(x^2 - 2 x + 2)^3},
\]

we assume it

\[
\frac{A x + B}{(x^2 - 2 x + 2)^3} + \frac{A' x + B'}{(x^2 - 2 x + 2)^3}.
\]

By reducing to a common denominator, we find

\[
x^2 - 2 x^2 + x - 3 = \frac{A x + B + (A' x + B')(2 x + 2)}{(x^2 - 2 x + 2)^3}.
\]

One of the roots of the equation \( x^2 - 2 x + 2 = 0 \) is \( x = 1 + \sqrt{-1}. \) This being substituted for \( x, \) the equation becomes

\[
-2 + \sqrt{-1} = A + B + A' \sqrt{-1} - 3.
\]

Hence the two equations are \( A + B = -3, \) and \( A' = -1. \) Substituting the values of \( A \) and \( B \) in the equation, we have

\[
x^2 - 2 x^2 + 2 x = (A' x + B')(2 x + 2);
\]

and taking the fluxions, and dividing by \( dx, \)

\[
3 x^2 - 4 x + 2 = (A' x + B')(2x - 2) + &c.
\]

By again substituting \( 1 + \sqrt{-1} \) for \( x, \) this equation becomes \( -2 + 2 \sqrt{-1} = -2 A' + 2(A' + B') \sqrt{-1} \); hence \( A' = 1, B' = 0; \) therefore the proposed fraction is equivalent to

\[
\frac{x + 3}{(x^2 - 2 x + 2)^2} + \frac{x}{x^2 - 2 x + 2}.
\]

118. The decomposition of the rational fraction \( \frac{U}{V} \) into partial fractions, requires that the denominator \( V = \Lambda x + B x^2 + C x^3 + \ldots \) \( + 1, \) be resolved into its real factors of the first or of the second degree, which can only be effected by the resolution of an equation of the 4th order. This problem, however, cannot be completely resolved, except in the lower degrees, and particular cases of the higher, in the present state of analysis. When the function \( V \) has the form \( x^n + 2 a x + 1, \) (\( a \) being less than unity,) or when it can be reduced to that form, it may be elegantly resolved into its factors by the trigonometrical tables, as explained in Analytique des Equations Numeriques. On the decomposition of rational fractions, see Euler Inst. Cal. Differentialis Pars. Profi. cap. xi.

Fluents of Rational Fractions.

119. We have seen, that every rational fraction may be reduced to partial fractions, which have these forms,

\[
\frac{A}{x - a} \quad \frac{A}{(x - a)^2} \quad \frac{A}{(x - a)^3} \quad \frac{A}{(x - a)^4}.
\]

\[
\frac{A x + B}{x^2 + px + q} \quad \frac{A x + B}{(x^2 + px + q)^2} \quad \frac{A x + B}{(x^2 + px + q)^3}.
\]

\( A, B, p, q, n, \) being constant quantities, and the factors of \( x^2 + p x + q \) imaginary quantities. If we make \( x = z - \frac{1}{2} p, \) and put \( \beta = q - \frac{1}{2} p^2, \) the two last fractions are transformed to

\[
\frac{A z + B'}{x^2 + \beta} \quad \frac{A z + B'}{(x + \beta)^2}.
\]

Hence the fluents of rational fractions may be comprehended in four cases.

Case I. The fluent of \( \frac{d}{dx} \frac{A x}{x^2 - 2 x + 2} \) is \( \Lambda \times \int \frac{1}{x - a} + \frac{1}{x - a} \) (Art. 114, Rule III.) But \( \frac{d}{dx} \frac{A x}{x^2 - 2 x + 2} = \frac{2 a x - x^2}{a^2 - x^2}, \)

and then the fluent is also \( \Lambda \times \int \left\{ \frac{1}{x^2 - a^2} \right\} \) (Art. 116).

Example 2.) therefore the fluent of \( \frac{d}{dx} \frac{A x}{x^2 - a^2} \) is

\[
\frac{1}{2 a} \left\{ \int (a + x) - 1 \right\} (a - x) + 1 \int (c + x).
\]

In like manner, \( \frac{d}{dx} \frac{A x}{x^2 - 2 x + 2} = \frac{2 d x}{2 x - x^2} + \frac{2 d x}{x + 1} \) has for its fluent \( -2 x - 2 \int (x - 2) = \frac{2 d x}{2 x - x^2 + 1} \) or

\[
\int \frac{c}{x^2 - 2 x - 2}.
\]

Case II. The fluent \( \frac{A x}{x^2 - a^2} \) has for its fluent

\[
\frac{A}{(n - 1)(x - a)^{n - 1}}.
\]

* For the management of impossible or imaginary quantities, see Algebra, Art. 190-194.
We have found (art. 116, Ex. 6) that 
\[
\frac{d}{dx} \left( \frac{x^3}{x^2 - 3x + 1} \right) = \frac{2}{x^2 - 3x + 1} \cdot \frac{d}{dx} \left( \frac{1}{x^2 - 3x + 1} \right) - \frac{1}{x^2 - 3x + 1} \cdot \frac{d}{dx} (x^2 - 3x + 1)
\]

Therefore, the fluent of the fraction is

\[
2 \int (x^2 - 3x + 1) \, dx
\]

CASE III. The fraction \( \frac{Ax + B}{z^4 + \beta^2} \) \( dz \) may be resolved into \( \frac{A}{z^4 + \beta^2} \) \( dz \). The fluent of the first of these is \( \frac{A}{2} \tan \left( \frac{z}{\beta} \right) + C \) (art. 114, Rule III.) and the fluent of the second is \( \frac{A}{2 \beta} \arctan \left( \frac{z}{\beta} \right) + C \).

Hence, by the rule of indeterminate co-efficients, we have

\[
\int \left( \frac{2n - 3}{n - 1} \right) \frac{dz}{(z^2 + \beta^2)^n} = 0.
\]

From these equations we find

\[
K = \frac{1}{2(n - 1) \beta^2}.
\]

This last, again, is reducible to another, in which the exponent is \( n - 2 \), and so on, until we come to the fluent of \( \frac{dz}{z^2 + \beta^2} \); which is known by Rule V., art. 113.

The fraction \( \frac{x^4 + 2x^3 + 3x^2 + 3}{(x^2 + 1)^3} \) \( dx \) will serve to exemplify this formula; when decomposed it becomes

\[
\left( -\frac{2x + 1}{x^2 + 1} \right) \frac{dx}{(x^2 + 1)^2} + \left( \frac{2x + 1}{x^2 + 1} \right) \frac{dx}{x^2 + 1}.
\]

The first terms of each of the two first fractions give

\[
\int \frac{dx}{(x^2 + 1)^2} = \frac{x}{4(x^2 + 1)^2} + \frac{1}{2} \int \frac{dx}{x^2 + 1}.
\]

This last term, joined to the term \( \int \frac{dx}{(x^2 + 1)^2} \) of our second fraction, gives \( \int \frac{dx}{(x^2 + 1)^2} \); we have in like manner

\[
\frac{2}{x^2 + 1} + \frac{7}{8(x^2 + 1)^2} + \frac{1}{x^2 + 1}.
\]

Lastly, joining this term to the third fraction, we find

\[
\frac{dx}{x^2 + 1} = \frac{1}{(x^2 + 1)^2} \text{ (tan. } = x) \text{.}
\]

The different parts united give

\[
\frac{7}{8(x^2 + 1)^2} + \frac{1}{x^2 + 1} + \frac{1}{(x^2 + 1)^2} \text{ for the complete fluent.}
\]
121. It appears that the fluent of every rational fraction is either an algebraic quantity, or else expressible in finite terms, by circular arcs and logarithms, so that granting the possibility of resolving a rational function into its factors, this branch of the calculus is perfect.

Leibnitz shewed first how to find the fluents of rational fractions in the Acta Eruditorum, 1702 and 1703. But he did not fully comprehend the theory, for he made it a question whether it was possible to express the fluent of \( \frac{a^4}{x^4} \) by the circle and logarithms.

John Bernoulli followed in the same path as Leibnitz, but their methods were very laborious: the theory was, however, completed, by the discovery of Cotes, which we have already noticed, (art. 116.)

On this branch of the subject, see John Bernoulli, Opera; Cotes, Harmonia Mensurarum; De Moivre, Miscellanea Analytica; Simpson, Essays on several subjects, and Fluxions, Vol. 11.; Landen, Mathematical Lucubrations, Part VII. Euler, Inst. Cal. Diff. et Integra-

Of the Fluents of Irrational Functions.

122. We have shewn how the fluent of every rational algebraic function may be found; the same method will apply to all such irrational functions as can be rendered rational by transformation. Let us consider, in the first place, fluents, in which the terms are singly radicals, such as

\[ \sqrt{x + x^3} \frac{dx}{x + x^3} \]

it is easy to see that by making \( x = z^3 \), the irrationality disappears, and as \( dx = 3z^2 dz \), the fluent is transformed to

\[ 6(\frac{z^6}{z^6+1})\frac{dz}{z} = 6z^6 dz + 6z dz - \frac{6z dz}{z^6+1} \]

which presents no difficulty.

Let the fluent be \( \frac{\sqrt{x}}{x-1} \) \( \frac{dx}{x} \); put \( x = z^3 \), then \( dx = 2dz \), and the fluent is transformed to

\[ \frac{2z^3 dz}{z^3-1} = 2 \frac{dz}{z} + \frac{2dz}{z^3-1} \]

of which the fluent is \( 2z + \log(z-1) - \log(z+1) \), or

\[ 2\sqrt{x} + 1 - \frac{c}{\sqrt{x} + 1} \]

123. We are now to consider any function whatever affected by the radical \( \sqrt{A + Bx + Cx^2} \); which may be also expressed thus, \( \sqrt{C} \sqrt{\frac{A}{C} + \frac{B}{C} x + x^2} \)

There will be two cases, according as \( x^3 \) is positive or negative.

Case I. When the radical has the form \( \sqrt{a + bx + cx^2} \); let us assume

\[ \sqrt{a + bx + cx^2} = x + \alpha, \quad \text{or} \quad x + \alpha, \]

hence we find \( a + bx + cx^2 = 2ax + x^2 \),

\[ x = \frac{2a - \alpha}{b + 2x} \]

\[ dx = \frac{2(bx + x^2) \alpha}{(b + 2x)^3} \]

Thus the radical, or \( x = \pm x \), will be rendered rational, as well as the proposed function.

For example, let the fluent be \( \frac{dx}{\sqrt[4]{a + bx + cx^2}} \). By putting the radical \( x = z - x \), it becomes \( \frac{z^4 + bz + a}{2b + 2z} \), and the proposed fluent is transformed to \( \frac{dx}{\sqrt[4]{a + bx + cx^2}} \); the fluent of which is \( l \left( \frac{2z + b}{2z + a} \right) \). Let us put \( \begin{cases} x = z & \text{when } a < 0 \text{ and } b < 0, \\ x = z & \text{when } a > 0 \text{ and } b > 0, \end{cases} \)

Hence, \( \int \frac{dx}{\sqrt[4]{a + bx + cx^2}} = \begin{cases} c \left[ x + \frac{b}{a} + \sqrt[4]{a + bx + cx^2} \right] & \text{when } a < 0 \text{ and } b < 0, \\ c \left[ x + \frac{b}{a} + \sqrt[4]{a + bx + cx^2} \right] & \text{when } a > 0 \text{ and } b > 0. \end{cases} \)

Instead of \( dx \), put its value \( \frac{dz}{2z^2} \) \( (a + z) \), and then, taking the fluent, and substituting, we find

\[ y = c + \frac{1}{2} \sqrt{a^3 + z^3} + \frac{1}{2} a \sqrt{a^3 + z^3} \]

If we put \( dy = \frac{-dx}{\sqrt[4]{1 - x^4}} \) under this form \( dy \sqrt{-1} \)

\[ \frac{dx}{\sqrt[4]{x^4 - 1}} \] taking the fluent, we have

\[ y \sqrt{-1} = 1 \left\{ x + \sqrt[4]{x^4 - 1} \right\} + c. \]

If \( y \) be an arc of a circle, \( x \) is its cosine (Rule (D), art. 26.) and \( \sqrt{x^4 - 1} = \sqrt{-1} \), \( y \); the equation of the fluents is therefore

\[ x \pm y \sqrt{-1} = 1 \left\{ \cos y \pm i \sin y \right\} \]

The constant correction \( c \) in this case must be 0, because when \( x = 1 \), \( y \) ought to vanish. Moreover we prefix the sign \( \pm \), because the sign of \( \sqrt{-1} \) may be either + or —. Hence, \( c \) being the radical number in Napier’s System of Logarithms (art. 12.) by the theory of logarithms,

\[ \cos y \sqrt{-1} = 1 \left\{ x + \sqrt[4]{x^4 - 1} \right\} + c. \]

\[ \cos y \sqrt{-1} = 1 \left\{ x - \sqrt[4]{x^4 - 1} \right\} \]

\[ \sin y \sqrt{-1} = 2 \left( e^{-y/2} - e^{y/2} \right) \]

\[ \sin y \sqrt{-1} = 2 \left( e^{-y/2} + e^{y/2} \right) \]

Lagrange considered these formulae as one of the most beautiful analytical discoveries of the past age. They were first given by Euler. For a different mode of investigating them, see Arithmetic of Sines (29).

124. Case II. Let the radical be \( \sqrt{a + bx + cx^2} \); the preceding method cannot now be applied without introducing imaginary quantities: But in this case the trinomial \( a + bx + cx^2 \) is the product of these two real factors,

\[ x + \frac{1}{2} \sqrt{(b + 4a) - \frac{1}{4} b^2 + 4a} \]

Let them be denoted by \( x - a \) and \( x + a \), and let us assume

\[ \sqrt{a + bx + cx^2} = \sqrt{\left\{ (x - a)(x - a) \right\} \left\{ (x - a)(x - a) \right\}} \]

* To prove that the factors are always real, it is to be observed, that as \( a + bx - x^2 \) is supposed a positive quantity, \( 4a + 4bx - 4x^2 = 4a + 4a - (b - 2x)^2 \) will also be positive, but \( (b - 2x)^2 \) will always be positive, therefore \( b^2 - 4a \) must also be positive, and \( b^2 + 4a \) a real quantity.
Then, squaring and suppressing the common factor, we have \( \beta - x = (x - a)^2 \); hence
\[
x = \frac{\beta - x + a^2}{1 + z^2}, \quad d z = \frac{2 (\beta - a) z d z}{1 + z^2}.
\]
\[
\sqrt{a + b x - x^2} = (z - a) = \frac{(\beta - a) z}{1 + z^2}.
\]
These functions, as expressed by \( z \), are all rational.

Let the fluxion \( \frac{d x}{\sqrt{a + b x - x^2}} \) be proposed; then, making the above substitution, it is immediately transformed to \( \frac{2 d z}{1 + z^2} \); the fluent of which is \( -2 \text{arc} (\tan. = z) \), therefore, because \( z = \sqrt{\beta - x} \), we have
\[
\int \frac{d x}{\sqrt{a + b x - x^2}} = -2 \text{arc} \left\{ \text{tan.} = \sqrt{\beta - x} \right\}
\]
If we suppose \( a = 1, b = 0 \), then, because \( 1 - x^2 = (1 + x)(1 - x) \), we have \( \alpha = -1, \beta = 1 \); in this case, the formula becomes
\[
\int \frac{d x}{\sqrt{1 - x^2}} = -2 \text{arc} \left\{ \text{tan.} = \frac{1 - x}{1 + x} \right\}
\]
The fluent of this fluxion is otherwise expressed by \( \text{arc} \left( \sin. = x \right) + c' \) (Art. 114. Rule V.).

If \( d y = d x \sqrt{a^2 - x^2} \), by applying the transformation, observing that \( a = -a, \beta = a \), we find
\[
d y = -8 a^2 z^2 d z
\]
The fluxion may now be found by the rules for rational fractions.

The same mode of transformation will apply to the first case, when the roots of the equation \( x^2 + b x + a = 0 \) are real. The radicals \( \sqrt{a + b x + x^2} \), and \( \sqrt{a + b x - x^2} \) may also be transformed by making \( x = -\frac{1}{2} b \) in the first case, and \( x = \pm \sqrt{a - b} \) in the second; they then take the forms \( \sqrt{a^2 + b^2} \), and \( \sqrt{a^2 - b^2} \). In the latter case, the irrationality may be removed by making \( \sqrt{a^2 - b^2} = a - u z \), for then
\[
\frac{2 a u}{u^2 - 1} \frac{d z}{d x} = -2 a d u \frac{u^2 - 1}{d x}
\]
It is thus that \( \sqrt{a^2 - b^2} \) becomes \( \sqrt{b^2 - z^2} \), by putting \( z = b - z ; \) the fluent may now be found by Rule V. art. 114. Again, making \( \sqrt{b^2 - z^2} = b - u z \), the fluxion is changed from its second form to \( \frac{2 d u}{u^2 - 1} \), a fluent of which the fluent has been repeatedly assigned.

Of Binomial Fluxions.

126. We propose now to find the fluent of
\[
K x^{m+n} d x (a + b x^n - p)^p
\]
\( m, n, p, \) being any numbers whatever, whole or fractional, positive or negative.

In the first place, we put
\[
x = a + b x^n;
\]
Hence, \( x = \left( \frac{z - a}{b} \right)^n \). Raising now both members of this equation to the power \( m + 1 \), and taking the fluxions, we get

\[\text{VOL. IX. PART II.}\]
FLUXIONS.

We now make \(1 + a x^{-1} = z^3\), from which \(x = (z^3 - 1)^{-1} a\); by raising both sides to the \(6\)th power, and taking the fluxions, we get

\[ x^{-1} d x = -\frac{z^3(z^3 - 1)}{a^2} d z. \]

Hence, by substituting, the fluxion is transformed to

\[ -\frac{1}{a^2} (1 - z^{-1}) d z, \]

of which the fluent is

\[ c - \frac{1}{a^3} (z + \frac{1}{2} z^{-1}) = c - \frac{3 z^1 + 2 a}{2 a^2} \sqrt{(x^1 + a)^3}. \]

In like manner, the fluxion \(x^3 d x (a^3 + x^3)\) becomes \(4 d z (z^3 - a z^1)\), by making \(a^3 + x^3 = z^3\); hence the fluent is

\[ \frac{1}{z^3} \sqrt{(a^3 + x^3)} (4 x^2 - 3 a^2) + c. \]

128. When the indices do not satisfy one of the two conditions specified in art. 126, the fluxion cannot be rendered rational by any known method; we may, however, reduce it to the most simple form of which it will admit, by means of the formula \(\int u d t = u t - \int d u \) (art. 114. rule IV.)

Let us put \(u = x^p\) and \(d t = x^m d x\), then \(d u = p \frac{m}{p} x^{m-1} d x\); hence,

\[ \int x^m d x = \frac{x^{m+1}}{m+1} + b \int x^p - x^{m+1} d x. \]

But \(z = a + b x^p\), and \(d z = n b x^{p-1} d x\), therefore,

\[ \int x^m d x = \frac{x^{m+1}}{n b} + \frac{m+1}{m+1} \int x^{p-1} x^{m+1} d x. \]

Again, because \(z^p = x^{p-1} z = z^{p-1} (a + b x^p)\), therefore

\[ \int x^m d x = a \int x^p d x - x^{p-1} b \int x^p d x + b \int x^{p-1} x^{m+1} d x. \]

These values (1) and (2) being put equal, we find

\[ b (m+1 + n p) \int x^{p-1} x^{m+1} d x = \frac{a (m+1 + n p)}{m+1} \int x^{p-1} x^{m+1} d x. \]

Change now \(p - 1\) into \(p\), and \(m + n\) into \(m\), and we have

\[ \frac{(A)}{\int x^m d x, z^p = \frac{x^{m+1} + 1}{m+1 + n p} \int x^{m+1} d x, z^{p-1}}, \]

and putting for the last term of equation (2) its value as given by (3), we get

\[ \frac{(B)}{\int x^m d x, z^{p-1}} = \frac{a (m-n+1)}{b (m+1 + n p)} \int x^{m+1} d x, z^{p-1}. \]

129. We shall now shew the use of these formulæ, in which it must be recollected that

1. Formula (A) makes the fluent of \(x^m z^p d x\) depend on that of \(x^{m+1} z^p d x\), and again this last on the fluent of \(x^{m+1} z^p d x\), and so on; it therefore serves to diminish the exponent of \(x\) out of the binomial, so at last to bring the fluent to depend on that of \(x^{m+1} z^p d x\), \(i\) being any whole positive number.

2. Formula (B) serves to diminish the exponent \(p\) by 1, 2, 3, &c. units, and thus to make the fluent of \(x^m z^p d x\) depend on that of \(x^{m-1} z^p d x\).

3. By resolving the equations (A), (B), so as to bring the fluent in the second member to one side of the equation, then substituting \(m-n\) instead of \(m\), in the first formula, and \(p-1\) instead of \(p\) in the second, we find

\[ \frac{(C)}{\int x^m d x, z^p = \frac{a (m-n+1)}{b (m+1 + n p)} \int x^{m+1} d x, z^{p-1}}. \]

These formulæ serve, on the contrary, to increase the exponents of \(x\), out of the binomial, and in it, and are useful, when the one or the other is negative.

4. These formulæ shew the law according to which the terms of a fluent are formed: thus, it is easy to see that the fluent of

\[ \frac{1}{(1-x^2)} \]

has the form

\[ (A x+B x^2+C) \sqrt{(1-x^2)} \]

By taking the fluxion of this expression, we may find the co-efficients, \(A\), \(B\), \(C\), by the method of indeterminate co-efficients, with less trouble than by applying the general formula.

130. We shall now indicate a mode of finding fluents, remarkable on account of its simplicity, and the numerous instances in which it may be applied. Taking the fluxion of \(x^m \sqrt{(1-x^2)}\), we shall find, after taking the fluents and transposing,

\[ \frac{(E)}{\int x^m d x = \frac{1}{2} \int x^{m-1} d x}. \]

By taking the expression \(x^{m-1} \sqrt{(1-x^2)}\) in the same manner, we get

\[ \frac{(F)}{\int x^m d x = - \int x^{m-1} \sqrt{(x^2+1)} + \frac{1}{2} \int x^{m-1} d x}. \]

By dividing the numerator and denominator by \(a\), the radicals in these expressions may be changed into \(\sqrt{(1+x^2)}\) and \(\sqrt{(x^2+1)}\), and then formulæ (E) and (F) make the fluent at last depend on

\[ \frac{(125)}{\int x^m d x = \frac{1}{2} \int x^{m-1} d x} \text{ or } \int x^m d x, \text{ if } n \text{ is odd; } \]

\[ \int x d x, \text{ or } \int x d x, \text{ if } n \text{ is even. } \]

The two first fluents come immediately under Rule II. art. 114, by putting \(x^2 = 1\), or \(1+x^2 = z^2\), from which \(x d x = -x d x = d z\); the third has been assigned in art. 124; the fourth is the arc, of which the sine is \(x\). For example, we have
of exponential functions.

132. It appears, from art. 26, rule (C), that

\[ \int a^x \, dx = \frac{a^x}{\log a}. \]

Let \( V \) be any algebraic function of \( ax \), then, because

\[ dx = \frac{d(ax)}{a \cdot 1(a)}, \]

if we put \( a^x = u \), we have \( V \, dx = V \, du \), \( u \cdot 1(a) \), an expression which, with regard to \( u \), has an algebraic form. For example, let \( V = \frac{x^m}{(2 \, a \, x - a^2)} \),

\[ \int \frac{x^m}{(2 \, a \, x - a^2)} \, dx = \frac{x^{m-1}}{m} \int \frac{2 \, a \, x - a^2}{2 \, a \, x - a^2} \, dx. \]

\[ \int a^x \, dx \left( z + \frac{dz}{dx} \right) = z e^x + c. \]

For example, let \( z = x^3 - 1 \); then \( \frac{dz}{dx} = 3x^2 \), and

\[ \int a^x \, dx \left( 3 \, x^2 + 3x - 1 \right) = c \left( x^3 - 1 \right) + c. \]

133. In other cases, we may have recourse to the method of integrating by parts, (art. 114. Rule IV.) Thus, let the fluxion be \( x^a \, dx \); then, by the formula

\[ \int u \, dt = u \cdot 1(a) - n \int u \cdot x^{n-1} \, dx. \]

By treating \( a \cdot x^{n-1} \, dx \) in the same manner, and repeating this as often as is necessary, we find

\[ \int a^x \, dx = \frac{a^x}{1(a)} - \frac{a^x}{2(a)} + \frac{a^x}{3(a)} - \frac{a^x}{4(a)} + \cdots = \frac{1.2.3 \cdots n}{1(a)} \cdot \frac{a^x}{n}. \]

In this series, \( 1^2(a) \), \( 1^3(a) \), &c. mean the square, the cube, &c. of \( 1(a) \).

134. If the exponent \( n \) is negative, by following the same method, we may increase the exponent of \( x \). Accordingly, from the formula \( \int u \, dt = u \cdot 1(a) - n \int u \, x^{n-1} \, dx \), making \( u = a^x \), and \( t = \frac{dx}{x^a} \), we find

\[ \int a^x \, dx = \frac{a^x}{(n - 1) \, x^{n-1}} + \frac{1}{n - 1} \int a^x \, x^{n-1} \, dx. \]

By repeating this transformation, we bring the fluent

\[ \int \frac{a^x \, dx}{x^n} \] to depend on \( \int \frac{a^x \, dx}{x}. \] This last fluent has long exercised the ingenuity of analysts in endeavouring to reduce it to circular arcs or logarithms, but without success. It appears to be a transcendental of a peculiar kind. For want of a rigorous method, we may employ a series; thus, putting \( \Lambda \) for \( 1(a) \), we have, by art. 53,

\[ a^x = 1 + \Lambda \, x + \frac{\Lambda^2 \, x^2}{2} + \frac{\Lambda^3 \, x^3}{2 \, 3} + \cdots + c. \]

Therefore, multiplying by \( \frac{dx}{x} \), and taking the fluents, we find

\[ \int \frac{a^x \, dx}{x} = l(x) + \Lambda \, x + \frac{\Lambda^2 \, x^2}{2} + \frac{\Lambda^3 \, x^3}{2 \, 3} + \cdots + c. \]

135. If \( n \) be a fraction, either of the preceding methods will serve to reduce the exponent of \( x \) to some fraction between 0 and \( +1 \) or \( -1 \); and then, recourse may be had to the method of infinite series, which we are afterwards to explain.

Whatever has been done in regard to the fluxion of \( x^a \, dx \), will apply equally to \( z \, dx \), \( z \) being the number of which Nap. log. is unity, we have \( d(z^x) = e^x \, dz \)

\[ + e^x \, z \, dx; \text{ therefore,} \]

\[ \int \frac{a^x \, dx}{x} = l(x) + \Lambda \, x + \frac{\Lambda^2 \, x^2}{2} + \frac{\Lambda^3 \, x^3}{2 \, 3} + \cdots + c. \]

136. Let it now be required to find the fluent of \( \log_{\text{Nap}} z \, dx \); putting \( l^x (z) \) to denote the nth power in the Napierian log. of \( x \), and supposing \( z \) to be any algebraic function of \( x \).

Let \( n \) be a positive integer, then recurring to the

\[ \int \frac{a^x \, dx}{x} = l(x) + \Lambda \, x + \frac{\Lambda^2 \, x^2}{2} + \frac{\Lambda^3 \, x^3}{2 \, 3} + \cdots + c. \]
FLUXIONS.

1. Method. We may make \( \sin x \), or \( \cos x = z \), and then any fluxion containing the sine and cosine of an arc, and its fluxion may be transformed into an algebraic function. For example, let \( \sin x = z \), then

\[
\cos x = \sqrt{1 - z^2}, \quad d x = \frac{d z}{\sqrt{1 - z^2}};
\]

\[
\sin m x \cdot \cos^n x d x = w m d z \left(1 - z^2\right)^{m-1}.
\]

1. If \( n \) is an odd number, the radical in the transformed expression disappears.

2. If \( m \) is an odd number, then the exponent of \( z \) out of the binomial, when increased by unity, will be a multiple of 2, its exponent in the binomial. Thus, one of the conditions (the first) of art. 126, will be satisfied; and therefore the fluxion may be made rational.

3. If \( m \) and \( n \) are even numbers, then the second condition of art. 126, will be satisfied. As an example of this method, let

\[
\int \sin x \, d x.
\]

\[
\int \frac{z^2 \, d z}{\sqrt{1 - z^2}} = - \frac{1}{4} \cos x (3 - \cos^2 x) + c.
\]

140. II. Method. It follows, from art. 26, rule D, that

\[
\int d x \cos k x = \frac{1}{k} \sin k x + c,
\]

\[
\int d x \sin k x = - \frac{1}{k} \cos k x + c.
\]

Now, we have shewn (Aritmetic of Sines) how to develop the powers of \( \sin x \) and \( \cos x \) into series, the terms of which are multiples of \( x \); therefore, every fluxion of the form \( \cos^m x \cdot d x \), or \( \sin^m x \cdot d x \), may be transformed into a series of fluxions, of the forms \( d x \cos k x \), \( d x \sin k x \); and hence the fluxions may be found from the preceding formulæ. Thus, because

\[
\cos^3 x = \frac{1}{10} \cos 5 x + \frac{5}{10} \cos 3 x + \frac{5}{8} \cos 3 x,
\]

(Arithmetic of Sines, Formule (S), therefore,

\[
\int \cos x \, d x = \frac{1}{80} \sin 5 x + \frac{5}{48} \sin 3 x + \frac{5}{8} \sin 3 x + c.
\]

This method is often used, because it is easier to find the sines and cosines of the multiples of an arc than the powers of its sine and cosine. As the expression \( \cos^m x \cdot \sin^n x \), may also be resolved into a series, of which the terms are the sines and cosines of the multiples of \( x \), the fluent of \( \cos^m x \cdot \sin^n x \cdot d x \), may be found as in the preceding example.

141. III. Method. The sine and cosine of an arc may be expressed as exponential quantities, by the formulæ of art. 123; and then the fluxions of any fluxions into which they enter, may be found by art. 132—134.

142. IV. Method. This proceeds by the formulæ

\[
\int u \, d t = u t - \int t \, d u,
\]

where \( u \) is put for \( l(x) \). The fluent of this last function can only be expressed by a series, as we have already observed in art. 134.

138. When \( n \) is a positive or negative fraction, the fluent may be made to depend upon a similar fluent, in which \( n \) is between \( 0 \) and \( +1 \), or \( -1 \). This last can only be expressed by an infinite series.

Of Circular Functions.

139. There are several methods of finding the fluxions of such expressions as contain trigonometrical functions.

Of circular functions.
FLUXIONS.

145. When the exponents of the sine and cosine are both negative, we multiply the numerator by \(\cos^2 x\) and the denominator by \(\cos^2 x\), and we have

\[
\frac{d}{dx} \sin^m x \cos^n x = \cos x \sin x + \sin x \cos x
\]

By repeating this operation, we come to fractions having only sin. x, or cos. x, in the denominator.

When \(m = 0\), as sin. x cos. x is sin. 2x, the denominator sin. x cos. x becomes \(\frac{1}{2} \sin. m(3x)\).

146. We shall conclude this branch of the subject, by finding the fluxents of four of the more elementary circular functions.

The first is \(\frac{dx}{\sin x}\), put \(\cos x = z\), and it becomes \(-\frac{dz}{\cos^2 x}\). The fluent of this expression has been given in Art. 119. Case I; hence

\[
\int \frac{dx}{\sin x} = \ln (c + \frac{1}{2}) \left\{ \frac{1 - \cos x}{1 + \cos x} \right\} = \ln \left\{ \sqrt{1 + \cos x} \right\}
\]

And as cos. x = \(1 - 2 \sin^2 \frac{x}{2} = 2 \cos^2 \frac{x}{2} - 1\) (Arithmetic of Sines, formula (T)); therefore, \(1 - \cos x\) becomes \(\sin^2 \frac{x}{2}\), and \(1 + \cos x\) becomes \(2 \cos^2 \frac{x}{2}\), so that

\[
\int \frac{dx}{\cos x} = \ln (\tan \frac{x}{2}) + c
\]

2. By a like process, putting \(\cos x = z\), we find

\[
\int \frac{dx}{\cos x} = \ln \left( \frac{1 + \sin x}{1 - \sin x} \right)
\]

If in the formula \(\frac{1 - \cos x}{1 + \cos x} = \tan \frac{x}{2}\), we put \(\pi - x\) instead of \(x\), \((\pi\) being \(180^\circ)\), we get

\[
\int \frac{1 - \cos x}{1 + \sin x} = \tan \left( \frac{1}{2} \pi + \frac{1}{2} \right)
\]

therefore, \(\int \frac{dx}{\cos x} = \ln \left( \tan \left( \frac{1}{2} \pi + \frac{1}{2} \right) \right) + c\).

3. Let the fluxion be \(\frac{d}{dx} \cos x\). In this case, the numerator is the fluxion of the denominator, therefore (Art. 114. Rule III)

\[
\int \frac{dx}{\sin x} = \int \frac{dx}{\tan x} = \int \frac{dx}{\cot x} = \int \left\{ \frac{c}{\cos x} \right\}
\]

4. In like manner,

\[
\int \frac{dx}{\sin x} = \int \frac{dx}{\tan x} = \int \frac{dx}{\cot x} = \int \left\{ \frac{c}{\cos x} \right\}
\]

Of the Constant Correction of a Fluent.

147. Let \(P\) be the variable part of the fluent of \(z dx\) (\(z\) being a function of \(x\)), and \(c\) the constant quantity which ought to be added, in order that the fluent may be the most general possible, we have \(\int z dx = P + c\).

While we regard the fluent merely as a function, of which the fluxion is to be identical with a proposed fluxion, \(c\) may be any constant quantity whatever; but when the fluent results from the solution of a particular problem, it generally happens, that the constant quantity \(c\) has to satisfy some condition, which restricts it to a determinate value. If, for example, it be propo-
sed to find the area $CEQP = s$, (Fig. 14,) comprehen-
ded between the ordinates $CE$, $PQ$, of which the absciss-
are $AB = a$, and $AQ = b$; because $ds = ydx$ (art. 71.)
in general, $s = \int f y dx + P + c$. But let us suppose, that
when $x$ becomes $a$, $P$ becomes $A$, then, corresponding
to the particular case of $x = a, s = A + c$. Now in the
present case, when $x = a$, then $s = 0$; therefore, $c$
is restricted to the magnitude that makes $A + c = 0$, that is,
$c = - A$, hence $s = - A$; and if in this expression we
put $b$ instead of $x$, we have the area, or the value of $s$,
between the limits of $x = a$, and $x = b$.

Again, let us suppose that $u$ and $x$ are two variable
quantities, so related, that $du = x^a dx$, then, in general,

$$u = \frac{x^{a+1}}{a+1} + c.$$ But let us farther suppose it known,

that when $x = a$, then $u = k$. In this case, $k = \frac{a^{a+1}}{a+1} + c,
and hence $c = k - \frac{a^{a+1}}{a+1}$, and, in the question under con-
sideration, it can have no other value; therefore $u = \frac{x^{a+1} - a^{a+1}}{a+1} + k$. In this manner, we may determine the
value of the constant correction $c$.

Supposing $a$ to be the value of $x$, when the fluent
$= 0$, then $a$ is called the origin of the fluent; and it is
said to begin when $x$ has that value; and to end when $x$
has completed the change in its magnitude, so as to have
passed from $x = a$ to $x = b$. These values of $x$ are the
limits of the fluent. When neither the origin nor the
limits of a fluent are assigned, it is said to be in-
definite; and, in order to be complete, it must contain a
constant arbitrary quantity. When the limits of the fluent
are assigned, it is definite. Thus, supposing $A$ to be the
value of the fluent when $x = a$, and $B$ its value when $x = b$, then $A - B$ is the definite fluent. As $c$ has the
same value in $A$ and $B$, it disappears from the defi-
nite fluent, which may therefore be found by putting
$x = a$, and $x = b$ in the indefinite fluent, and subtracting
the first result from the second. All this will be illus-
trated by examples as we proceed.

**Fluents found by Infinite Series.**

148. When a fluent cannot be assigned in definite terms
by algebraic quantities, nor by circular arcs nor logarithms,
then recourse must be had to methods of approxi-
mation. Let $\int z dx$ be the fluent. If we develop the
function $z$ into a series, proceeding according to the ascen-
ding or descending powers of $x$, and multiply the terms by $dx$, and then take the fluents, their sum will evidently be the fluent sought. We shall now give ex-
amples.

Ex. 1. Let the fluent of $\frac{dx}{x+a}$ be required, which,
we know, comprehends in it $l . (x+a)$, (Rule (B), art.
26). By algebraic division,

$$\frac{1}{a+x} = \frac{1}{a} \frac{x}{a} + \frac{x^2}{a} + \frac{x^3}{a^3} + \&c.$$ Therefore, multiplying by $dx$, and taking the fluent
of each term, we find

$$\int \frac{dx}{a+x} = \frac{x}{a} \frac{x}{a} + \frac{x^3}{3 a^3} + \frac{x^4}{4 a^4} + \&c.$$ In the most general expression for the fluent, $c$ may
be any constant quantity whatever; but regarding it
as expressing the value of $l . (x+a)$, $c$ is restricted to a
particular value. To determine this, we know that
when $x = 0$, then $l . (x+a)$ becomes $l . (a)$; but when
$x = 0$, all the terms of the series except $c$ vanish, there-
fore $c = l . (a)$, and

$$(x+a) = l . (a) + \frac{x}{a} - \frac{x^2}{2 a^2} + \frac{x^3}{3 a^3} - \&c.$$ as we have already found, (Art. 53.)

Ex. 2. To find the fluent of $\frac{1}{x} + \frac{1}{x^2}$, we expand it by
division into the series $dx = - x^2 dx + x^3 dx + \&c.$ Then taking the fluents of the terms, we find

$$\int \frac{dx}{x^2} = x - \frac{x^3}{3} + \frac{x^7}{5} + \&c.$$ As this fluent is that of an arc, of which the tangent
is $x$, and radius unity, (Art. 35), by giving a suitable value to $c$, the fluent must express that arc. To
determine $c$, we must consider, that when the tangent
$= 0$, then the arc $= 0$; therefore the fluent ought to va-
nish when $x = 0$; hence $c$ must be $= 0$,

$$\text{arc} = x - \frac{x^3}{3} + \frac{x^3}{5} - \frac{x^5}{7} + \&c.$$ which is the series originally found by James Gregory,
and perhaps afterwards by Leibnitz. Hence the ratio
of the diameter to the circumference may be found, (see
**Arithmetic** of Sines, Art. 52); and the number
3.14159265... which expresses the measure of two
right angles, and is commonly indicated by the char-
acter $\pi$.

Ex. 3. Let the fluent of $\frac{dx}{\sqrt{(1-x^2)}}$ or $dx (1-x^2)^{-\frac{1}{2}}$
be required. In this case, we must expand the radical
into a series by the binomial theorem, (Art. 53. or 54.
See also **Algebra**, Art. 323.) which will give

$$(1-x^2)^{-\frac{1}{2}} = 1 + \frac{x^2}{2} + \frac{1.3 x^4}{2.4} + \&c.$$ hence we have

$$\int \frac{dx}{\sqrt{(1-x^2)}} = x + \frac{x^3}{2.3} + \frac{3 x^5}{2.3.5} + \&c.$$ This fluent is the same as that of an arc, of which the
sine is $x$, (Rule (D) Art. 26.); now the arc vanishes
when $x = 0$, therefore, by making $c = 0$, the series
will express the arc. If we suppose the arc to be $\frac{x}{2}$ of
the circumference, or $\frac{1}{2}$, then $x = \frac{1}{2}$. Therefore ob-
erving, that the arc of $30^\circ$ is $\frac{1}{2} \pi$, we have

$\frac{\pi}{2} = \frac{1}{2} \frac{1}{2} + \frac{1}{2} \frac{3.2}{2.3.2} + \frac{3.5}{2.3.5.2} + \&c.$

149. John Bernoulli invented a general expression
for any fluent, which is analogous to Taylor's formula
for any function of a binomial. Let $z$ be any function
of $x$, then any fluent whatever, containing only one
variable quantity, may be represented by $z d x$; em-
ploying now the formula $\int u d t = u t - \int u d u$, we have

$$\int z d x = x z - \int z d x$$

$$\int x d z = \int \frac{d z}{d x} x d x = \frac{1}{2} x^2 d z - \frac{1}{2} \int x^2 \frac{d z}{d x} = x^2 \frac{d z}{d x}$$

$$\int x^2 d z = \int \frac{d z}{d x} x d x = \frac{1}{2} x^2 d z + \frac{1}{2} \int \frac{d z}{d x} x^2 d x$$

Instead of $\int x d z$, $\int x^2 \frac{d z}{d x}$, &c. substitute their
values, and put c for the constant quantity, which serves to complete the fluent, and we have

\[ \int \frac{dz}{a + x} = \ln(a + x) + c. \]

This is Bernoulli’s Theorem. It may be otherwise readily deduced from Taylor’s theorem. If in the development we make \( x = 0 \), all the terms, with the exception of the constant quantity, vanish, therefore \( c \) is the value of the fluent when \( x = 0 \).

**Example.** To find the fluent \( \frac{1}{a + x} \) of \( a + x \) by this method: When \( x = 0 \), then \( \frac{1}{a + x} \) becomes \( 1 \). (a), therefore \( c = 1 \). (a) : And because \( z = \frac{1}{a + x} \), therefore \( \frac{dz}{dx} = \frac{-1}{(a + x)^2} \), \( \frac{dx}{dx} = \frac{2}{x} \), \&c. and

\[ 1 + x = 1 \frac{1}{x} + \frac{1}{2} (a + x) \] + \( \frac{1}{2} (a + x)^2 \) + \( \frac{1}{3} + (a + x)^3 + c. \]

This series differs from that found in last article, but the one may be transformed into the other.

**Quadrature of Curves.**

150. Let \( x = AQ \) (Fig. 14.) be the abscissa of a curve, \( y = PQ \), the ordinate, and \( s \), the area \( CQ \), comprehended between the indefinite ordinate \( PQ \), and \( CE \), an ordinate having a given position. We have found, (art. 71.), that \( ds = y \, dx \), so that \( s = \int y \, dx \).

We are now to apply this formula to particular examples.

**Example 1.** Let the curve be a parabola, (Fig. 10.) in this case, \( a \) being put for the parameter, \( y^2 = x \), and \( y = \frac{1}{2} x^2 \), and also \( ds = d \, dx = \frac{1}{2} x^2 \), therefore, taking the fluent, (art. 114.),

\[ s = \int y \, dx = \frac{1}{2} \, \frac{1}{2} x + c = \frac{1}{2} \, y \, x + c. \]

Let us suppose the fluent to begin at the vertex \( A \); then, when \( x = 0 \) we ought to have \( s = 0 \). The general equation of the fluents in this case becomes

\[ 0 = x + c \]

therefore \( c = 0 \), and \( s = \frac{1}{2} y \, x \), which agrees with what was found in Conic Sections, (Sect. VII. Prop. 1.) If \( s \) were supposed to begin when \( x \) had some given value \( b \), we would have \( = \frac{1}{2} \, a \, b \, x + c \)

then \( c = - \frac{1}{2} \, a \, b \), and \( s = \frac{1}{2} \, \left( \frac{1}{2} x^2 - b^2 \right) \).

Ex. 2. Let the curve be a circle, (Fig. 9.) and suppose the origin of the co-ordinates \( x = OQ \), and \( y = LP \) to be at \( O \) the centre; put \( a \) for the radius. By the nature of the circle \( y = \sqrt{a^2 - x^2} \), therefore \( y \, dx = \sqrt{(a^2 - x^2)} \) : Apply to this the fluxion

\[ \int y \, dx = \frac{1}{2} \, a \, b \, \sqrt{a^2 - x^2} + c. \]

Similarly, \( s = \int y \, dx = \frac{1}{2} \, a \, y \, + \frac{1}{2} \, a \, \int \frac{y}{\sqrt{a^2 - x^2}} \) dx.

Now, (Art. 114, Rule V.) the fluent of \( \frac{a \, dx}{\sqrt{a^2 - x^2}} \)

is the circular arc of which the radius is \( a \) and the sine \( x \), and this arc, supposing \( AD \) a quadrant, is \( PD \); let it be denoted by \( z \), and we have

\[ s = \frac{1}{2} \, x \, y + \frac{1}{2} \, a \, z + c. \]

This is the complete fluent, which holds true, whatever is its origin. Let us now suppose that the fluent begins when \( x = 0 \) ; in this case \( z = 0 \), and as then \( s = 0 \), it follows that \( c = 0 \); hence

\[ s = \text{area ODP} = \frac{1}{2} \, x \, y + \frac{1}{2} \, a \, z. \]

Now if we join OP, the triangle \( POQ = \frac{1}{2} \, x \, y \), therefore the sector POD = \( \frac{1}{2} \, a \, z \).

Ex. 3. Let the curve be an ellipse, (Fig. 11.) of the semi-transverse and semiconjugate axes are \( a \), and \( b \); suppose the origin of the co-ordinates to be at \( \Delta \), one extremity of the transverse. The equation of the curve is \( y^2 = \frac{b^2}{a^2} (2 \, a - x^2) \); hence

\[ s = \int y \, dx = \frac{b}{a} \int \sqrt{(2 \, a - x^2)} \]

If a circle be described on the transverse axis as a diameter, and \( y^2 \) be put for \( p \), the ordinate of the circle, corresponding to the common abscissa \( x \), and \( x^2 \) for the circular area \( AP \), we have \( y^2 = \int (2 \, a - x^2) \), and

\[ x = \int y \, dx = \frac{b}{a} \int \sqrt{(2 \, a - x^2)} \]

Hence, the variable parts of these two fluents have to each other the constant ratio of \( b \) to \( a \), or of \( b \) to \( a \), and as they begin together, the fluents themselves must have the same ratio, that is \( s = s' : b : a \), as was shewn in Conic Sections, (Sect. VII.)

**Ex. 4.** Let the curve be an equilateral hyperbola, (Fig. 25.) and \( AY \), \( AY \), its asymptotes; and let it be required to find the area included by the hyperbolic arc \( CP \), the straight lines \( CE, PQ \), which are parallel to one asymptote, and \( EQ \), the segment of the other asymptote, intercepted between them. Let \( CE \), one of the parallels, have a given position. Put \( AE = a \), \( EC = b \), \( AQ = x \), \( QP = y \). By the nature of the curve.

\[ xy = a \, b \]

\[ s = \int y \, dx = \frac{b}{a} \int \sqrt{(2 \, a - x^2)} \]

By the nature of the problem, when \( x = a \), then \( s = 0 \); therefore in this case, \( 0 = ab \, \int (a + c) \), hence \( c = -ab \, \int (a) \), and

\[ s = ab \left\{ \frac{1}{2} \, (a - b) \right\} = ab \, \int (\frac{x}{a}) \]

If we suppose \( a = b = 1 \), then \( s = \frac{x}{a} \), hence the area \( s \) is expressed by the Napierian logarithm of the abscissa \( AQ \), and these areas serve as a geometrical representation of Napier’s logarithms. On this account they were called by the early writers hyperbolic logarithms, but improperly, as any logarithms whatever may be represented by hyperbolic areas. See Logarithms.

**Ex. 5.** Let the hyperbolic area \( PAQ \) be required, supposing \( PQ \) to be an ordinate to \( CA \), the transverse axis (Fig. 26.) Let \( C \), the centre, be the origin of the co-ordinates \( OP = x \), \( = y \), the semitransverse axis \( = a \), the semiconjugate \( = b \). The equation of the curve

\[ (\text{Conic Sections, Sect. VIII.)} = \frac{b}{a} \sqrt{(x - a^2)} \]

hence
We may proceed with this fluent, as with that in Example 2d, or else by formula (1), art. 128, which gives at once

\[ \int \frac{dx}{\sqrt{\left(x^2 - a^2\right)}} = \frac{x}{a} \sqrt{x^2 - a^2} - \frac{x}{2a} \int \frac{dx}{\sqrt{\left(x^2 - a^2\right)}} \]

Now, by art. 128,

\[ \int \frac{dx}{\sqrt{\left(x^2 - a^2\right)}} = \frac{1}{2} \left\{ \frac{a}{x} + \sqrt{x^2 - a^2} \right\} + c. \]

Therefore,

\[ s = \frac{b}{2a} \sqrt{x^2 - a^2} - \frac{ab}{2} \left\{ \frac{x}{a} + \sqrt{x^2 - a^2} \right\} - c. \]

Now, from the nature of the figure, when \( x = a \), then \( s = 0 \); therefore, in this case, the general equation becomes

\[ s = \frac{ab}{2} \left\{ \frac{1}{a} - c \right\} \]

hence \( e = \frac{ab}{2} \left\{ a - c \right\} \).

and

\[ s = \frac{b}{2a} \sqrt{x^2 - a^2} - \frac{ab}{2} \left\{ \frac{x}{a} + \frac{y}{b} \right\} \]

If we join CP, it is evident that \( \frac{1}{2} xy \) expresses the area of the triangle CPQ, therefore

Sector ACPL = \( \frac{ab}{2} \left\{ \frac{x}{a} + \frac{y}{b} \right\} \).

Ex. 6. Let APD be the common cycloid, (Fig. 12.) of which AB is the axis, AHB the generating circle, having its centre on the axis, AK a perpendicular to the axis at the vertex, and PR a perpendicular to AK from P any point in the curve; and let it be required to find the external area APR.

Let O be the centre of the generating circle; draw PQ perpendicular to AB, meeting the circle in H, and join OH. Put \( AR = x \), \( RP = y \), \( AO = a \), the angle \( AOH = \theta \). Then \( AQ = a \left( 1 - \cos \theta \right) \), \( AH = a \sin \theta \), and since, from the nature of the curve (see Epicycloid), \( PQ = AR = \) arc AH + HQ, therefore

\[ x = a \left( 1 - \cos \theta \right), \quad y = a \sin \theta \]

Now, this last fluent, or \( \int d\theta \sin^2 \theta \), is found, by art. 144, to be \( -\frac{1}{2} \cos \theta \sin \theta + \frac{1}{2} \theta \), therefore

\[ s = \frac{ab}{2} \left\{ \frac{x}{a} + \frac{y}{b} \right\} + c. \]

When \( v = 0 \), then \( s \) ought to vanish, therefore \( c = 0 \), so that putting for \( v \), \( \sin \theta \) and \( \cos \theta \) their values, we find

\[ s = \frac{b}{2a} \Delta O \times \text{arc} \text{AH} - \frac{1}{2} \Delta Q \times QH = \text{circ. seg.} \text{AH}. \]

This agrees with what was shown in the article Epicycloid.

Ex. 7. As an example of a polar curve, let us take the spiral of Archimedes, (Fig. 27.) Let A be the pole, AC the position from which the revolving radius AP begins its motion. Put \( AP = r \), the angle \( PAC = \theta \); and let \( a \) be a given line, and \( x = 3.14159 \), &c. The nature of the curve is expressed by the equation \( 2a \pi r = a \theta \). Now if \( x \) denote the area \( A^P \), we have found (art. 72.) that in curves expressed by a polar equation, \( d \theta = \frac{1}{2} r^2 d \theta \). In the present case \( d \theta = \frac{2}{a} d r \), therefore

\[ s = \frac{1}{2} \int r^2 d \theta = \frac{\pi}{3} \int r^2 d r = \frac{\pi}{3} a^2 r^3 + c. \]

If we suppose the fluent to begin when \( r = 0 \), then \( c = 0 \); therefore, when \( r \) has made a complete revolution, so that \( v = 2 \pi \), and \( r = a \), the area generated will be \( \frac{2}{3} a^3 r = \frac{1}{3} \text{of a circle, of which } a \text{ is the radius.} \)

To find the space which \( r \) passes over in the next revolution, the fluent must be taken between \( v = 2 \pi \), and \( v = 4 \pi \), that is, between \( r = a \), and \( r = 2 a \). Corresponding to the first value of \( r \), we have \( s = \frac{2}{3} a^2 r \); the difference of these, which is the area required, is \( \frac{7}{3} a^2 \).

151. As the area ECPQ (Fig. 14.) of any plane curve Fig. 14. is expressed by the fluent \( \int f y d x \), in which \( y \) (PQ) is some function of the abscissa \( x \) (AQ), on the other hand, every fluent \( \int f y d x \) may be represented geometrically by the area of a curve, of which \( x \) is the abscissa, and \( y \) the ordinate. The geometrical representation of a fluent shows distinctly wherein it differs from a common analytic function, such as \( a + a x^2 \), or \( a \), or sin. \( x \), &c. These last have determinate values, corresponding to any assigned value of \( x \), and the value of each function is altogether independent of its preceding or subsequent values. But the magnitude of the quantity expressed by the fluent \( \int f y d x \) is the increment that a certain function receives while \( x \) passes from one degree of magnitude to another.

152. The analogy between a curvilinear area and a fluent, points out a general method of approximating to the value of any fluent whatever, and to any degree of nearness. Let the fluent \( \int f y d x \) be required between the limits of \( x = a \) and \( x = b \). Let CPD (Fig. 28.) be a curve, such that \( AQ \) and \( QP \), the co-ordinates which begin at a given point \( A \), may represent \( x \) and \( y \). In the axis \( AB \), take \( AQ = a \), the least value of \( x \), and \( AQ'' = b \), its greatest value, and draw the ordinates \( PQ, P^Q, Q''P'' \); then the area \( PQQ''P'' \) will be the geometrical expression for the fluent \( \int f y d x \), between the limits of \( x = a \), and \( x = b \); and by whatever means that area can be found, the same will apply to the determination of the fluent.

Let \( QQ'' \) be divided into any number of equal parts \( QQ', Q^Q', \&c. \), and let the ordinates \( P^Q', P^Q''', \&c. \), be drawn; these will divide the figure into the curvilinear trapezia \( PP'QQ', PP''Q^Q' ', \&c. \). Let a series of rectangles \( PP', PP''', \&c. \), be constructed, each having the shortest of two adjoining ordinates for its height; these will fall entirely within the figure, supposing the curve to be entirely concave or convex towards the axis. Let another series \( PP', PP'', \&c. \), be constructed, each having the longest of two adjoining ordinates for its height; and all these will extend beyond the figure. Because \( AQ = a \), and \( QQ'' = b - a \), and the number of parts into which \( QQ'' \) is divided is known, the abscissa \( AQ', AQ'^', \&c. \), will be known, and from the nature of the curve, the corresponding ordinates \( P^Q', P^Q''', \&c. \), will be known. Hence we can find the inscribed rectangles \( PP', PP'', \&c. \), the sum of which will be less than the curvilinear space \( PP'QQ'Q'' \); also the circumscribed rectangles \( PP', PP'', \&c. \), the sum of which will exceed that space. Thus two
limits may be found, between which the curvilinear space or the fluent is always contained. Besides, these limits may differ by as small a quantity as we please, for their difference is manifestly the rectangle \( PM'SR \), which is contained by \( PM = QQ' \), and \( PR = DUQ' = PQ \), the difference of the extreme ordinates; and \( QQ' \) may be as small as we please.

If chords \( PP', PP'' \), &c. be drawn, the sum of rectilinear trapezisms \( QQ'PP', \) &c. will be a nearer approximation to the area or fluent, than either the circumscribing or inscribed parallelograms. As an example of the application of this method, let it be proposed to approximate to the fluent \( \int_{x=0}^{x=1} \frac{dx}{1 + x^3} \), between the limits of \( x = 0 \) and \( x = 1 \).

In this case, the equation of the curve \( CD \) is \( y = \frac{1}{1 + x^3} \).

Let \( QQ'' \) be divided into ten equal parts, then, putting \( x = 0, x = 0.1, x = 0.2, \) &c. to \( x = 1 \), we obtain eleven equidistant ordinates; the numerical values will be as follows:

<table>
<thead>
<tr>
<th>The 1st</th>
<th>1.00000</th>
<th>The 7th</th>
<th>.78529</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

By the elements of geometry, the area of the rectilinear figure formed by the trapezisms, is found by adding together all the ordinates except, the first and last, and half the sum of the first and last, and multiplying the result by the common breadth of the trapezisms, which is \( 1 \). This rule gives \( 7.84981 \) for the area or value of \( \int_{1}^{x} \frac{dx}{1 + x^3} \) between the proposed limits. This area is slightly more than the mean of the tangents to the curve, \( y = \frac{1}{1 + x^3} \), evaluated by the method of exhaustions (art. 35). We have obtained a better approximation to it by a series, (art. 148). If in that series we put \( x = 1 \), the result becomes \( \frac{1}{1 + 1} \) or \( \frac{1}{2} \), and the difference between this converges too slowly to be of any use.

154. We shall now make some general remarks relating to quadratures.

1. If an area \( s \) is contained between two curves \( CD \), Fig. 29, or two branches of the same curve, (Fig. 29), let \( PQ = y \), and \( p Q = y' \) be their ordinates corresponding to the common abscissa \( \Delta Q = x \), then \( \int y \, dx \) is the area \( CEQP \), and \( \int y' \, dx \) is the area \( CEQP' \); therefore \( \int (y - y') \, dx \) is the area included between the two curves.

2. Or employing the calculus of infinitesimals, we may regard the area \( CP = s \) as made up of an infinite number of trapezoids \( PP'PP'' \); each having \( dx \) for its breadth, and these again, as made up of an infinite number of rectangles \( m_j \), of which the sides are \( dx \) and \( dy \), so that \( dx \, dy \) will be an element of the first order of the area \( s \). Then, to obtain \( s \), the fluxion or differential \( dx \, dy \) must be integrated from \( y = y' \) to \( y = y' \), and again the result between the limits \( x = \Delta Q \) and \( x = AE \), so that we arrive at the final result as before.

4. The entire area of a curve that returns into itself, is found by taking the fluxion of \( (y - y') \, dx \) from the least to the greatest value of \( x \).

5. The ordinate \( y \) of the curve ought never to become infinite between the limits of the area.

6. If a curve cuts the axis of the abscissa between the limits of the area, the parts on each side of the axis must be found separately, because the one is positive and the other negative, and the fluent requires to be taken without any regard to the latter sign.

For example, let \( K0ACD \) be a curve of which the equation is \( y = x - x^2 \); (Fig. 30) the origin of the coordinates being at \( A \), the curve passes through \( A \), and meets the axis in \( H \) and \( K \), so that \( AH = AK = 1 \). The general expression for the area \( s \) is \( \frac{1}{2} x^2 - \frac{1}{2} x^2 + c \). If we suppose it to begin at the point \( E \) where \( x = AE = \sqrt{\frac{1}{2}} \), then, at the origin of the fluent, \( 0 = \frac{1}{2} x^2 + e \); hence \( c = - \frac{1}{2} x \), and \( x = \frac{1}{2} \sqrt{\frac{1}{2}} \). If the area is to end at \( E \) where \( x = AE = \sqrt{\frac{1}{2}} \), we shall find \( x = 0 \), which indicates that the areas \( ECH \), \( HDF \) are.
are equal but with opposite signs. In fact, putting 
\( x = 1 \), we find that the area \( \text{E}CH = \frac{1}{2} \), and taking the 
fluent \( \frac{1}{2} x^2 - \frac{1}{2} y^2 + c \) between the limits \( x = \Lambda H = 1 \) 
and \( x = AF = \frac{1}{2} \), we get the area \( \text{HDF} = - \frac{1}{2} \). In 
lke manner, the area taken from \( K \) to \( H \) comes out 
\( = 0 \) because the space \( \text{KOA} \) below the axis is equal to 
the space \( \text{ACH} \) above it.

153. Although it is not possible to square 
every curve, yet it is possible to assign any number of curves 
whatever that are perfectly quadrable, that is, which may 
have their area expressed by algebraic functions of the 
co-ordinates. Let \( u \) denote any function whatever of 
the abscissa \( x \), then if we assume the ordinate \( y = \frac{du}{dx} \),
we have \( y \, dx = u \, dy \), and \( \int y \, dx = u + c \). For example, 
let \( u = a \, x^{\alpha+1} \), then \( \frac{du}{dx} = (\alpha+1) \, a \, x^{\alpha} \). Hence 
every curve of which the co-ordinates \( x \) and \( y \) are so 
related, that \( y = (\alpha+1) \, a \, x^{\alpha} \) is quadrable in algebraic 
terms, and has its area \( = a \, x^{\alpha+1} + c \). The case of 
\( \alpha = -1 \), is however not included in the formula.

154. As the quadrature of any curve, and the 
determination of a fluent \( y \, dx \) \( y \) being a function of \( x \) of 
a given form \( \) are problems convertible into one another, 
they are sometimes considered as belonging to one and 
the same theory. On this subject, see Legendre, Exercices 
de Calcul Integral, Part III.

Of the Rectification of Curves.

157. We have found, (art. 75), that \( x \) and \( y \) being 
the co-ordinates, and \( z \) any arc of a curve \( d x = \sqrt{(d \, x^2 + d \, y^2)} \); we shall now apply this formula to 
some examples.

Example 1. Let the curve be a parabola, (Fig. 10.) 
\( \Lambda Q = x, \, \Lambda Q = y \), the parameter \( = 2a \). The equation of 
the curve \( 2a \, d \, x = y^2 \), gives \( a \, d \, x = y \, dy \), and 
\( d \, y = \sqrt{(y^2 + a^2)} \); the fluent (art. 128, formula (B), 
and art. 123) is
\[ z = c + \frac{y}{2a} \sqrt{(y^2 + a^2)} + \frac{1}{2} \, a \, \log \left( \frac{y + \sqrt{(y^2 + a^2)}}{a} \right). \]

If the fluent begin at \( \Lambda \), then, when \( y = 0\), \( z = 0 \); in 
this case the general formula becomes \( c = \frac{1}{2} \, a \, \log (a) \), 
and hence \( c = - \frac{1}{2} \, a \, \log (a) \); therefore \( z = y \sqrt{(y^2 + a^2)} \).

Ex. 2. Let the curve be what is called the second 
cubical parabola, of which the equation is \( y^3 = a \, x^3 \).

In this case the general formula gives \( d \, z = \frac{dy}{\sqrt{(1 + \frac{9}{4} a^2)}} \); hence, by art. 126,
\[ z = \frac{1}{\sqrt{2a}} \sqrt{(1 + \frac{9}{4} a^2)} + c. \]

This curve is perfectly rectifiable, and is remarkable on 
account of its having been the first curve that was 
rectified. This discovery was made by Neil, and 
forwards by Van Heuraet. (Wallis' Algebra, chap. 77, 
and Schooten's edit. of De Cartes' Geometry, end of 
Part I.)

Ex. 3. Let the curve be a circle (Fig. 9.) of which 
the radius \( OA = a \), then, reckoning the co-ordinates 
\( \text{OQ} = x \) and \( \text{QP} = y \) from the centre, \( x^2 + y^2 = a^2 \)
\[ y = \sqrt{(a^2 - x^2)}, \frac{dy}{dx} = \frac{-x}{\sqrt{(a^2 - x^2)}} \text{ and } dz = \frac{dx}{\sqrt{(a^2 - x^2)}}. \]

We have already given the fluent of this expression 
by an infinite series, (art. 148, Ex. 3.) in the case of the 
rad. \( = 1 \). When the rad. is \( a \) we have only to sub-
stitute \( \frac{x}{a} \) for \( z \) and \( \frac{y}{a} \) for \( x \), we thus find
\[ z = x + \frac{x^3}{2.3. a^3} + \frac{3. x^5}{2.3.4. a^5} + \frac{3.5. x^7}{2.3.4.6. a^7} + &c. + c. \]

If the arc \( \text{AD} \) be a quadrant, and the fluent begin at 
\( D \), then when \( x = 0, \, z = 0 \); therefore in this case 
\( c = 0 \).

We have given a different series in art. 148, Ex. 2, 
for an arc, in terms of the tangent; and others may be 
found which shall express it by the cosine, cotangent, 
&c. from the formulæ of art. 35. But in no case whatever 
can an arc be expressed by trigonometrical lines 
in finite terms.

Ex. 4. Let the curve be an ellipse, (Fig. 31.) of Fig. 29, 
which the semitransverse axis \( CA = 1 \), the semiconjucate 
\( CB = c \), the eccentricity, which is \( \sqrt{(1 - e^2)} = e \).

Let \( C \), the centre, be the origin of the co-ordinates 
\( \text{OQ} = x \) and \( \text{PO} = y \), and put the arc \( \text{BP} \) (reckoned 
from the extremity of the conjugate axis) \( = z \). By 
the nature of the curve
\[ cy = \sqrt{(1 - x^2)}, \text{ hence } dy = \frac{-c \, x \, dx}{\sqrt{(1 - x^2)}} \text{, and } \]
\[ dz = \frac{1 - (1 - c^2) x^2}{\sqrt{(1 - x^2)}} \, dx = \frac{(1 - c^2 x^2)}{\sqrt{(1 - x^2)}} \, dx. \]

The fluent of this expression cannot be found in finite 
terms, even with the help of circular arcs or logarithms; 
therefore it can only be expressed by an infinite series. 
By the binomial theorem, we get
\[ \sqrt{(1 - x^2)} = 1 - \frac{1}{2} c^2 x^2 - \frac{1}{2} \frac{3}{2} c^4 x^2 - \frac{1}{2} \frac{5}{4} c^6 x^2 - &c. \]

We must now multiply each term of this series by 
\[ \sqrt{(1 - x^2)} \text{, and take the fluents, which will all be of } \]
the form \( \Lambda \int \frac{x^m}{\sqrt{(1 - x^n)}} \) and may be found by art. 130. 
Thus, putting \( \phi \) for the arc whose sine is \( x \), we get 
\( z = \text{elliptic arc} \text{ BP } = \phi \).

\[ \frac{1}{\sqrt{2.2.4.6.8}} \text{ c } = \frac{1.1.3.3.5}{2.2.4.6.8} \text{ c } = &c. \]

This expression vanishes when \( x = 0 \), as it ought, 
therefore it wants no correction. If we make \( x = 1 \), 
all the terms containing \( \sqrt{(1 - x^2)} \) vanish, and, as in 
this case \( \phi = \frac{1}{2} \pi \), we get the elliptic quotient
\[ AB = \frac{1}{2} \pi \left( 1 - \frac{1.1.3.3.5}{2.2.4.6.8} \text{ c } = \frac{1}{2} \pi \left( 1 - \frac{1.1.3.3.5}{2.2.4.6.8} \text{ c } = &c. \right. \right. \]

This expression converges pretty fast when \( c \) is small; 
but when \( c \) is nearly \( 1 \), it is hardly of any use. To 
have a complete solution, we ought to investigate ano-
FLUXIONS.

In a page of a document, the natural text is:

The length of a hyperbolic arc may be found exactly in the same manner, from its equation $e = \sqrt{x^2 - 1}$. There are several elegant properties of elliptic arcs, discovered by Fagnani in 1718, (Fag Op. T. II. p. 317.) which has led to considerable improvement in the fluxional calculus. It may be easily deduced from the formula given in art. 77, for the rectification of a curve.

Let $DE$ be a tangent at any point $D$ in the ellipse (Fig. 31.) Draw $CE$ from the centre perpendicular to the tangent, and parallel to it the semidiameter $CH$, which will be the conjugate to the length drawn from $C$ through $D$: also draw $HK$ perpendicular to the axis. As in example 4, let $CA = 1$, $CB = e$, the eccentricity $= e$, and further put $CE = p$, $DE = t$, the angle $ACE$ in the ellipse $= \theta$, and the elliptic arc $AD = z$.

Because $HK = e(x - CK)$ and $HK = CH \times \cos \phi$, also $CK = CH \times \sin \phi$, therefore $CH^2 \times \cos^2 \phi = e^2 (1 - \sin^2 \phi)$, and hence

$$CH = \frac{e}{\sqrt{(1 - e^2 \sin^2 \phi)}}$$

And since by a property of the curve, (Conic Sections, Sect. II. Prop. 20,) $CH \times CE = AC \times CB = c$; therefore

$$CE = p = \sqrt{(1 - e^2 \sin^2 \phi)}$$

And since in every curve expressed by an equation of this kind, (art. 77,) $d(z + t) = pd\phi$, therefore

$$d(z - t) = d\phi \sqrt{(1 - e^2 \sin^2 \phi)}$$

Let PQ be any ordinate to the axis, then, putting $CQ = x$, and the arc $BP = z$, we have found (Ex. 4. last art.) that $d = \frac{dx}{\sqrt{(1 - x^2)}}$. Let us now suppose $x = \sin \phi$, then it follows that $d = d\phi \sqrt{(1 - \sin^2 \phi)}$; we have also $1 - e^2 x^2 = 1 - \sin^2 \phi$, therefore

$$d = d\phi \sqrt{(1 - e^2 \sin^2 \phi)}$$

From formula (1) and (2) it immediately follows that

$$d(z + t) = dz$$

When $\phi = 0$, and consequently $\sin \phi = x = 0$, then $z$, $t$, and $z + t$ all vanish, therefore $c = 0$, and we have

$$z + t = z$$

That is, arc $AD + \tan. DE = arc BP$.

This is in substance Fagnani's theorem. It may be expressed in words at length, thus: Let $ABD$ be an elliptic quadrant, draw $DE$ a tangent to the curve at any point $D$, and $CE$ a perpendicular from the centre to the tangent: As radius to the sine of the angle $AC$, so make $AC$ to $CQ$, and draw the ordinate $QP$; the arc $AD$ reckoned from the excentricity of the transverse, together with the tangent $DE$, is equal to the arc $BP$ (reckoned from the excentricity of the conjugate axis.) Hence it appears that any arc of an ellipse being given, another arc may be assigned geometrically, such that their difference shall be equal to a certain assignable straight line, a circumstance which has been considered as remarkable.

Ex. 5. If we employ the same construction and the same notation in the hyperbola, (Fig. 32,) as in the ellipse; that is, if we draw a tangent at $D$, and $CE$ a perpendicular from the centre on the tangent, and if we put $CA = 1$, the eccentricity $= e$, the hyperbolic arc $AD = z$, the angle $ACE = \phi$, the perpendicular $CE = p$, the tangent $DE = t$, we shall find exactly as in the ellipse, that $p = \sqrt{(1 - e^2 \sin^2 \phi)}$, and (art. 77)

$$d(z - t) = d\phi \sqrt{(1 - e^2 \sin^2 \phi)}$$

In the ellipse $e$ is less than unity, but here $e$ is greater than $1$; and this circumstance makes an essential difference in the two fluxions: the one form is, however, reducible to the other, as was first shown by Landen in *Phil. Trans.* 1775. In either case, the flux may be found by developing $\sqrt{(1 - e^2 \sin^2 \phi)}$ into a series, then multiplying each term by $d\phi$, and taking the fluxes.

Ex. 6. Again, in the parabola (Fig. 23,) let $F$ be the focus, $A$ the vertex, $PE$ a tangent at $P$, and $P$ a perpendicular to the tangent; put the parameter $= a$, the angle $AFE = \phi$, the perpendicular $FE = p$, the tan. $PE = t$, the arc $PA = z'$; we have found (art. 89, Ex. 1,) that in the parabola $p = \frac{a}{2 \cos \phi}$, hence

$$d(z - t) = \frac{a d\phi}{2 \cos \phi}$$

and, by art. 146.

$$z = \frac{a}{2} \int d\phi \sqrt{(1 - e^2 \sin^2 \phi)}$$

This flux ion wants no constant quantity, because when $\phi = 0$, both sides vanish as they ought.

From this expression we might assign parabolic arcs, which should be to each other in the given ratio of one number to another, which was first done by John Bernouilli in 1698. (John Ber. Op. T. ii. p. 248.) See also *L'Hospital, Sect, Coniques*, page 382. This property of the parabola has some relation to Fagnani's theorems, for the ellipse and hyperbola:

Ex. 7. Let the curve be a cycloid of any kind, (Fig. 33,) of which DC is the axis, $DHC$ a circle described on the axis, of which the radius $= 1$, $PG$ an ordinate to the axis, which meets the circle in $H$. Put $DG = x$, $GP = y$, circ. $DH = v$, cycloidal $DP = z$. By the nature of the curve ('Eneycyclo') $x = 1 - \cos v$, $v = z + n + \sin v$, where $n$ is a given number, which in the common cycloid is unity. Hence $a = dv \sin v$, $dv = dv (n + \cos v)$ and

$$z = \sqrt{(1 - x \sin y)} = \frac{dy}{\sqrt{(1 + n^2 + 2 n \cos v)}}$$

Instead of $\cos v$, put $1 - 2 \sin \frac{\pi}{4} v$, and put $e$ for $\sqrt{(1 + n^2)}$ and we have.

$$\frac{1}{2}$$
FLUXIONS.

This fluent may evidently be expressed by an arc of an ellipse, also by the difference of an elliptic arc, and its tangent, (formulae (1), (2), art. 158.)

Ex. 8. Let the curve be the spiral of Archimedes, (Fig. 27.) In which AP = r, the angle CAP = v, the arc AP = x; the equation of the curve is $r = x$, where $a$ denotes a given line. In this case we apply the general formula $d z = \sqrt{r^2 (d x^2 + d r^2)}$, (art. 76.)

and as $d v = \frac{2 \pi}{a} d r$, we find

$$z = \frac{2 \pi}{a} \int d r \sqrt{\left(\frac{a^2}{x^2} + r^2\right)}.$$  

If this expression be compared with that for a parabolic arc, (Ex. 1, art. 157.) it will appear that these curves are equal, when $r$ is the ordinate of the parabola, and $\pi$ the parameter.

150. The early writers on fluxions endeavoured, as much as possible, to find simple geometrical representations of such fluents as could not be expressed by finite algebraic functions. They succeeded in representing such as involved the radical $\sqrt{a+bx+c}$, which can always be made rational, by circular and hyperbolic areas; when the fluent contained a radical of the form $\sqrt{(a+bx+c)x^2}$, in some cases they could express the fluent by elliptic and hyperbolic arcs, and in others by the surface of an oblique cone. Maclaurin was the first that treated at any length of this mode of expressing fluents, in his Fluxions, Book ii. chap. 3, and the subject was extended by D'Alembert, Mem. de Berlin, 1746 and 1748. Landen, in his Memoirs and Lectures, has arranged, in Tables, the various fluents that may be found in this manner. Lagrange and Legendre have since treated the subject in a manner purely analytical, and this last mathematician, in his Memoire sur les Transcendantes elliptiques, and more recently in Exer. de Cal. In. has reduced all fluents, in which the only radical is $\sqrt{a+bx+c}$, to three species; and he has shewn how the fluents may be expressed, by series which shall always converge rapidly.

160. As any number of curves may be found that are quadrical, so also curves may be found that are rectifiable. We shall now resolve this.

Problem. To find algebraic curves which may be rectified, or which may have their lengths expressed by algebraic functions of the co-ordinates.

Solution. Let CPD (Fig. 34.) be a curve such as is to be found, and let $\Delta Q$, $QF$ be the co-ordinates at $P$, any point in the curve. Draw the tangent $PE$, and from $A$ draw $AE$ perpendicular to the tangent. Put $AQ = x$, $QF = y$, the arc $AB = z$, the perpendicular $AE = p$, the tangent $PE = q$, the angle $EAB = u$. By formula (4), art. 77, we have in every curve whatever,

$$d z = p d u + \frac{d p}{d u} d u,$$

and $z = \int p d u + \frac{d p}{d u} d u$.

As $z$ is an algebraic quantity, we must have $p d u$ an algebraic quantity; let us suppose it $= U$, some function of $u$; then $p d u = d U$, and $p = \frac{d U}{d u}$: Thus the relation of $p$ to the angle $u$ is determined.

From $E$ and $P$ draw $Em$, $Pn$, perpendiculars to the co-ordinates; then observing that $PE = EAB = u$, we have $Em = EA \times \sin u = p \sin u$, $Am = EA \times \cos u = p \cos u$, $En = EP \times \cos u = t \cos u$, $Pn = EP \times \sin u = t \sin u$; therefore, $x = p \cos u + t \sin u, y = p \sin u - t \cos u$. But we found (formula (A), art. 77) that

$$t = \frac{d p}{d u},$$

then $d u = \frac{d U}{d u}$, and

$$x = \frac{d U}{d u} \cos u - \frac{d U}{d u} \sin u,$$

$$y = \frac{d U}{d u} \sin u + \frac{d U}{d u} \cos u,$$

and $z = U + \frac{d U}{d u}$. (3)

These equations give a complete solution of the problem; for by the first and second we may eliminate $u$, and obtain an equation involving $x$ and $y$ only. We can also determine $U$ and $\frac{d U}{d u}$ in terms of $x$ and $y$, and thence the value of $z$. For example, let us assume $U = 4a \sin \frac{1}{4} u + c$, then $\frac{d U}{d u} = 2a \cos \frac{1}{4} u, \frac{d U}{d u} = -a \sin \frac{1}{4} u$; hence

$$x = 2a \cos \frac{1}{4} u \cos u + a \sin \frac{1}{4} u \sin u,$$

$$y = 2a \cos \frac{1}{4} u \sin u - a \sin \frac{1}{4} u \cos u,$$

and $z = 3a \sin \frac{1}{4} u + c$.

By adding the squares of the values of $x$ and $y$, and putting $p = \cos \frac{1}{4} u + \sin \frac{1}{4} u$, we find

$$x^2 + y^2 = a^2 \left(\cos^2 \frac{1}{4} u + \sin^2 \frac{1}{4} u\right) = a^2 \left(1 + 3 \cos^2 \frac{1}{4} u\right),$$

and $x^2 + y^2 + a^2 = \cos \frac{1}{4} u$.

And by substituting $2 \sin \frac{1}{4} u \cos \frac{1}{4} u$ for $\sin u$, and $\cos \frac{1}{4} u - \sin \frac{1}{4} u$ for $\cos u$, in the value of $x$, we get

$$\frac{x}{a^2} = \cos \frac{1}{4} u.$$

From these two last equations we readily find

$$27 a^4 x^2 = (x^2 + y^2 - a^2)^3$$

for the equation of the curve, which appears to be a line of the 6th order; And as $z = 3a \sin \frac{1}{4} u + c$, therefore, by comparing its value with that of $x$, it may be expressed by $x$. The truth of these conclusions may easily be verified by putting $\varphi = \frac{1}{4} u$, and observing that $x = \frac{1}{4} a \cos \varphi + \frac{1}{4} a \cos 3 \varphi, y = \frac{1}{4} a \sin \varphi + \frac{1}{4} a \sin 3 \varphi, z = 3a \sin \varphi + c$.

Huygens resolved this problem by his theory of evolute curves (Horologium Oscillatorium, Pars III.) and Newton gave a solution upon principles deduced from the same theory, (Method of Fluxions, Prob. 10.) It also engaged the attention of Euler, (Nov. Comm. Acad. Petrop. T. v.) and Lagrange has given a solution, upon principles purely analytical, in his Calcul. des Fonctions Lecon, 19. The solution given here agrees with his in the result, but it has been obtained in a different manner.

Of the Content of Solids.

161. Let $\Lambda - PEp$ (Fig. 19.) be any solid formed by the rotation of a plane curve about its axis $AB$, then if $t$ denote the area $\Lambda Q = x$, and $PQ = y$, be the co-ordinates of $P$, any point in the curve, and $\ell$ the content of the solid, it follows, from art. 79, that

$$\ell = \pi \int y^2 d x.$$

We shall now apply this formula to some examples.
EXAMPLE 1. Let the generating curve be a parabola, which revolves about its axis. By the nature of the curve, \( y^2 = a \cdot x \), therefore in this case
\[
s = \pi \int a \cdot x \cdot dx = \frac{1}{2} \pi a \cdot x^2 + c = \frac{1}{2} \pi y^2 x + c.
\]
If we suppose the fluent to begin when \( x = 0 \), then \( c = 0 \); and as \( y^2 \) expresses the area of the base, it appears that the content of a paraboloid is half a cylinder of the same base and altitude.

Ex. 2. Suppose the solid to be a parabolic spindle (Fig. 35.), which is generated by the revolution of a parabolic arc ADB about AC, an ordinate to the axis. From \( P \), any point in the revolving curve, draw \( PQ \) perpendicular to the ordinate \( AC \), and PR perpendicular to the axis of the paraboloid; put \( DC = p \), \( AC = q \), \( CQ = PR = x \), \( PQ = CR = y \). By the nature of the curve, \( PR^2, AC^2 :: DR : DC \) (Conic Sections, Sect. IV., Prop. 13.), that is, \( x^2 : y^2 = p :: y : p \); hence \( p \cdot x^2 = p^2 \cdot y^2 - q^4 \), and
\[
y^2 = \frac{p^2}{q^4} (q^4 - 2 \cdot q^4 \cdot x^2 + x^4),
\]
and
\[
s = \int \frac{p^2}{q^4} \int (q^4 d x - 2 \cdot q^4 \cdot x^3 d x + x^4 d x),
\]
and taking the fluents of the several terms,
\[
s = \frac{p^2}{q^4} \left( \frac{x^4}{4} - \frac{q^4}{4} \cdot x^4 + \frac{x^6}{6} \right) + c.
\]
If the fluent commence when \( x = 0 \), then \( c = 0 \). And making \( x = q \), we get \( \frac{1}{4} \cdot p^2 \cdot q^4 \) for half the content of the solid generated by the curve ADB.

Ex. 3. Let the solid be a spheroid ABP (Fig. 36.) produced by the revolution of an ellipse about \( AB \), either of the axes. Put the fixed axis \( AB = a \), the revolving axis \( DE = b \), also \( A Q = x \), \( Q P = y \). From the nature of the ellipse, \( y^2 = \frac{b^4}{a^4} (a^2 - x^2) \), hence
\[
s = \frac{b^4}{a^4} \int (a^2 - x^2) d x = \frac{b^4}{a^4} \left( \frac{a^2}{2} \cdot x^2 - \frac{x^4}{4} \right) + c.
\]
If the fluent commence when \( x = 0 \), then \( c = 0 \). By making \( x = a \), we get \( \frac{1}{2} \cdot \pi \cdot b^4 \) for the content of the whole spheroid; and supposing \( a = b \), we have \( \frac{1}{2} \cdot \pi \cdot a^4 \) for the content of a sphere, whose diameter is \( a \); and as \( \frac{1}{2} \cdot \pi \cdot b^4 \) is the area of a section of the sphere or spheroid through the centre, it appears that the whole solid is \( \frac{1}{2} \) of the circumscribing cylinder; which is the well-known theorem of Archimedes.

In the same manner we may find the content of a hyperboloid.

162. If the solid APE (Fig. 19.) is not formed by the revolution of a curve about a fixed axis; yet, if it can be referred to an axis \( AB \), so that \( PE \) any section of the solid by a plane perpendicular to that axis, is some known function of \( AQ = x \), the segment of the axis between the plane and a given point \( A \), its content may be found from the very same formula. For it may be proved exactly, as in art. 179, that a ratio of equality is the limit of the ratio of the increment of the solid to a cylinder, whose base is a section of the solid, and altitude the increment of the axis, so that if \( a \) denote the solid, and \( X \) denote the area of the section \( PE \), we have
\[
\text{lim}_{x \to a} \frac{d_s}{d \cdot x} = X, \quad \text{and} \quad \int X d x = s.
\]

Ex. 1. Let \( P' E ' p' \) (Fig. 37.) be any plane figure whatever, and \( A \) a given point out of its plane: it is required to find the content of the coneal solid formed by a straight line, which, passing through \( A \), is carried round in the circumference of the figure \( P' E ' p' \).

Let \( AQ \), a perpendicular to the base of the solid, meet \( PE \), a section parallel to the base in \( Q \). Put the area of the base \( = b \), the perpendicular \( A B = p \), and let \( x \) and \( X \) denote as above. The section of any cone whatever, by a plane parallel to its base, being always similar to the base, we have \( p^4 : x^4 = b : X \), hence
\[
X = \frac{b^4}{p^4}
\]
and
\[
s = \int X d x = \frac{1}{p^2} \int x^2 d x = \frac{b^4}{3 \cdot p^2}.
\]

Here no correction is wanted, because when \( x = 0 \), then \( s = 0 \); and putting \( X \) instead of \( \frac{b^4}{p^4} \), we have
\[
s = \frac{x}{p^2} X, \quad \text{but} \quad X = X \quad \text{is the content of a cylinder whose base is} \quad X, \quad \text{and altitude} \quad x;\quad \text{and therefore every solid of this kind is one-third of a cylinder of the same base and altitude. This rule applies to cones and pyramids, whose bases are any figures whatever.}

Ex. 2. Let the solid be what is called a Groin (Fig. 38.), which is generated by a variable square \( e f / g \) moving parallel to itself, the section DAH, through the middle of the opposite sides, being a semicircle. Draw \( AB \) perpendicular to the plane of the base, put \( AB = p \), \( A Q = x \), \( Q P = y \); then \( y^2 = 2 \cdot p \cdot x = x^2 \) by the nature of the circle, but \( x y \) is the area of the section \( e f / g = X \); hence
\[
s = \int (8 \cdot p \cdot x d x - 4 \cdot x^2 d x) = 4 \cdot p^2 x^2 - \frac{4}{3} x^3.
\]

Here no correction is wanted, because if \( x = 0 \), then \( s = 0 \). When \( x = p \), then \( s = \frac{1}{3} \cdot p^3 \), the content of the whole solid.

Of the Surfaces of Solids.

163. In Fig. 20, let \( AB \) be the axis of a solid of revolution, and \( AP \) the generating curve; put \( AQ = x \), faces of so-PQ = y, the arc \( AP = z \), and the surface generated by the curve \( AP = v \). The general formula is in this case (art. 80.)
\[
v = 2 \pi \int y \sqrt{d x^2 + d y^2} = 2 \pi \int y d z.
\]

We shall now apply this to some examples.

Example 1. Let the solid be a sphere, of which the axis is \( AB \) (Fig. 36.), and let it be required to find the Fig. 36. surface of the segment, cut off by a plane \( PE \) perpendicular to the axis. Put the radius of the sphere \( = a \), \( AQ \) the height of the segment \( = x \); the radius of its base \( PQ = y \); by the nature of the figure, \( y^2 = 2 \cdot x \cdot x^2 \), hence \( y d y = (a-x) d x \), and
\[
d x^2 + d y^2 = \frac{y^2 + (a-x)^2}{y^2} d x^2 = \frac{a^2 \cdot d x^2}{y^2};
\]
and hence, \( d v = 2 \pi y \sqrt{(d x^2 + d y^2)} = 2 \pi a d x \), and
\[
v = 2 \pi a x.
\]

Here no correction is wanted, because we have supposed that when \( x = 0 \), then \( s = 0 \). Since \( 2 \pi a \) is the circumference of a great circle of the sphere, it appears, that the curve surface of any segment of a sphere is equal to a rectangle contained by the height of the segment, and a straight line equal to the circumference of a great circle of the sphere. From which it appears, that the whole surface of the sphere is four times the
Ex. 2. Suppose the curve $A^P$ to be a parabola (Fig. 19.), then putting $AQ=x$, $FP=y$, the parameter of the axis $=2a$, we have found (art. 157, Ex. 2.) that
\[\sqrt{(dx^2+dy^2)} = \frac{d}{y} \sqrt{(y^2+a^2)},\]
hence
\[ds = 2\pi y \sqrt{(dx^2+dy^2)} = \frac{2\pi}{a} dy \sqrt{(y^2+a^2)},\]
and taking the fluent (art. 122),
\[s = \frac{2\pi}{3a} (y^3+a^2)^{\frac{1}{3}} + c.\]

164. We have observed (art. 107-110), that the indefinitely small increments of quantities may often, on the grounds of convenience, be taken as their fluxions; and, indeed, this is in effect the same thing as to seek the limit of the ratio of the finite increments, and then to consider it as the ratio of the fluxions. We shall now give two examples of this application of the infinitesimals.

**Example 1.** Let it be required to find the surface of an oblique cone, (Fig. 39.)

Let $C$ be the centre of the base, $V$ the vertex, $VA$ the perpendicular from the vertex, meeting the base in $L$; join $CA$, meeting the circumference of the base in $H$; take $B$ any point in the circumference of the base $BC$, and draw $DB$ tangent at $B$ to the circumference $BC$, and join $CB$, $BA$, $DA$, $VE$. The triangles $VDE$, $VAE$, are right-angled at $D$ and $A$; therefore $VE^2 - EA^2 = VD^2 = DA^2$; hence $AE^2 - AD^2 = VE^2 = VD^2 = DA^2$; therefore $AD$ is the perpendicular to $VB$, and consequently parallel to $CB$.

Let us suppose the radius of the base to be $1$; put $a$ for the distance of the perpendicular from the centre; $p$ for $VA$ the altitude; and $\phi$ for the variable arc $HB$. The triangles $EBC$, $EAD$, are similar; hence $EC:CB :: EA:AD$; that is, $sec. \phi = \frac{1}{sec. \phi - a}$

\[AD = sec. \phi = \frac{1 - a \cos \phi}{1 - a \cos \phi}, \text{ therefore,}\]

\[DV = \sqrt{p^2 + (1 - a \cos \phi)^2}.\]

Take a point $b$ indefinitely near to $B$ in the circumference of the base of the cone, and join $Cb$, $Vb$; the small arc $Bb$ may be considered as coinciding with its tangent. We are now to consider the indefinitely little arc $Bb$ as the fluxion of $BH = \phi$, and the triangle $VBb$ as the fluxion of the conical surface which the line $VB$ has passed over, while it moved from the position $H$, along the arc $HB$. We have therefore $Bb = \phi \phi$, and, as the area of the triangle $VBb$ is $\frac{1}{2} Bb \times VB$, if we put $x$ for the surface of the cone, we have
\[dx = \frac{1}{2} d \phi \sqrt{p^2 + (1 - a \cos \phi)^2}.\]

This is the expression for the fluxion of any conical surface whatever, having a circle for its base. The determination of the flux has long exercised the ingenuity of mathematicians; and we observe, that Legendre had at last succeeded in expressing the whole surface of the cone (that is, the flux between the limits of $\phi = 0$, and $\phi = 2\pi$) by elliptic arcs, (exercises de Cal. Integ. p. 173.) But the indefinite fluent, or the expression for the surface corresponding to $\phi$ any arc whatever, has not been assigned by the areas or arcs of the conic sections, except for particular values of $a$ and $p$.

If we make $\cos \phi = x$, then $d \phi = \frac{dx}{\sqrt{(1 - x^2)}}.
\text{and, therefore, }\]
\[ds = -dx \sqrt{\left(p^2 + (1 - a^2 x^2)\right)/2\sqrt{(1 - x^2)}},\]

The fluent may now be found by a series, as in Ex. 4. of art. 157. Or a sufficiently near approximation to the fluent may be found by art. 152. If we suppose $a = 0$, we have the case of a right cone: in this case, $ds = \frac{1}{2} \phi \sqrt{1 + p^2}$, and $d \phi = \frac{1}{2} \phi \sqrt{1 + p^2}$, that is, the surface is half the product of the arc $\phi$, and the slant side of the cone.

Ex. 2. Suppose a circle to be described upon any radius of the base of a hemisphere, and upon this circle an upright cylinder to be raised, and prolonged to pierce the hemisphere; it is required to find the surface of the oval hole made in the spherical vault.

In Fig. 40. let $BFA$ be the base of the hemisphere, (which we may suppose to be horizontal), and $CA$ its radius, which is also the diameter of $CEA$, the base of the cylinder; let $DQA$ be a great circle of the sphere, the plane of which passes through the axis of the cylinder. This circle will divide the oval curve, which is the common section of the surfaces of the sphere and cylinder, and also that part of the surface of the sphere which is bounded by it into two equal and like parts, one of which is $\triangle D'AQD$.

Take $P$ any point in the curve $DPA$, and conceive a right line $PQ$ to pass along $DC$ the axis of the sphere, and through $P$, meeting the surface of the sphere in the quadrant $DPF$, its base in $CF$, and the curved surface of the cylinder in the straight line $PE$. Let $CF$ meet the circumference of the base of the cylinder in $E$, join $AE$ and $CP$.

The right-angled triangles $CEP$, $CEA$, opposite to the right angle in each, equal, and the side $CE$ common to both; therefore the triangles are equal, and the angle $ECP$ is equal to the angle $ECA$, hence the arc $EP$ is equal to the arc $FA$.

About $D$ as a pole, describe the small circle $IPQ$ to pass through $P$, and suppose another small circle $pq$ to be described indefinitely near to the former. We may consider the surface contained between $APD$ and $AQP$ as made up of an infinite number of spaces, such as $\delta p q Q$. The common breadth of which is the small arc $Qq$. Put $a$ for the radius of the sphere, and $p$ for the line $AF$, $FP$, and $AQ$ will each be equal to $a$, and $Qq$ will represent $a \phi$, the fluxion of the arc $AQ$; and because the radius of the small circle $IPQ$ is $a \cos \phi$, we have $\frac{a}{\cos \phi} = \frac{a}{\cos \phi}$, and $\cos \phi = a \cos \phi$. Therefore the sum of all the areas, that is,
\[\int a^2 \cos \phi d \phi = \text{the spherical surface $APQ$,}\]
(art. 153.) This fluent is $a^2(\phi \sin \phi + \cos \phi + c)$; but when $\phi = 0$, then the area $AIPQ = 0$, hence $c = a^2$, and the trilateral area $APQ$ is equal to $a^2(\phi \sin \phi + \cos \phi - 1)$. This expression, when $\phi$ is a quadrant ($\frac{1}{4} \pi$), gives $a^2 \pi - a^2$ for the whole area.

In the year 1692, Viviani, one of Galileo's disci-
ciples, proposed a geometrical enigma, which depended on the solution of the preceding problem: There is, said he, among the ancient monuments of Greece, a temple consecrated to Geometry; its form is circular, and it is covered by a spherical dome, having four equal windows, which are constructed with such art, that the remainder of the dome is absolutely quadrable: addressing himself to the analysts of that period, he requested them to say, how this might be done, adding, that he doubted not but that their secret art (the new calculus) would soon put them in possession of his enigma. It was not long before the meaning of this enigma was discovered; Leibnitz and Bernoulli resolved the problem the day they received it. (Act. Lip. v. iii. p. 92.) In France, L'Hopital gave a solution, and so did our countrymen Wallis and David Gregory; but it did not reach England until the year following that in which it was proposed.

Viviani's own solution was to this effect. On a vertical plane ACB passing through the centre of the sphere (Fig. 41.) describe two semicircles AHC, CKB, so that their diameters may be radii of the sphere, and may be in the same straight line; then, semicylinders which stand on these as bases will, when produced both ways, pierce the dome, and form four openings, which may serve as the windows of the temple. For, if the radius of the dome be a, it appears by the preceding problem, that the spherical surface of each window will be \( \frac{1}{4} a^2 \pi - a^2 \); and their sum \( 2a^2 \pi - 4a^2 \); now, the whole spherical surface of the dome is \( 2a^2 \pi \); therefore the remainder is \( \frac{1}{4} a^2 \), a space perfectly quadrable, for it is the square in the diameter of the base.

Viviani published his solution, but without a demonstration, along with other matters relating to geometry in 1692. There are various other curious geometrical theorems connected with the *Florine Problem*, as it is called. See Bosse, *Traite de Cal. Diff.* vol. ii. and by Ivory, in *Leuybourn's Math. Repository*, vol. i. part 2d. Euler, *Cal. Integ.* vol. iv. Supp. 6.

### Rectification of Curves of Double Curvature.

166. The nature of a line of double curvature has been explained in CURVE LINES. (Art. 51.) Let CPD be a curve of this kind. (Fig. 42.) referred to three co-ordinate planes XAY, ZAX, ZAY. From every point in the curve let perpendiculars PP', QQ' be drawn to the plane XAY; these will all be in the surface of a cylinder, that intersects the plane in a curve CP'D', which will be the projection of the proposed curve.

Again, from PP' draw P'Q', P'R' perpendicular to AX, AY. Put AP', or P'R' = z; AR', or P'Q' = y; PP' = x; the axes CP, CP', its projection CP' = v. Then \( dv = \sqrt{(dx^2 + dy^2)} \) (Art. 75). Now, if we suppose the cylindric surface CC'D'D to be extended upon a plane, the curve CP'D' will be changed into a common plane curve, and its projection CP'D' into a straight line, each of the same length as before. We may then consider \( v' = v \) and \( z = \) co-ordinates of the curve \( v \), and so we shall have \( dv = \sqrt{(dx^2 + dy^2 + dz^2)} \); therefore, by substituting for \( dv^2 \) its value \( dx^2 + dy^2 + dz^2 \), we find

\[
dv = \sqrt{(dx^2 + dy^2 + dz^2)}.
\]

This is a general formula for the rectification of any line of double curvature. By means of the two equations which express the nature of the line, we can express \( dy \) and \( dz \) by means of \( x \) and \( dx \), and then the fluxion of the curve will contain only a single variable quantity, and the fluent may be found by the common rules.

### Of Fluxional Equations of the first Order containing two Variable Quantities.

167. In the direct method of fluxions, (Art. 47-50.) we have shown how to pass from any proposed primitive equation to its fluxional equation of any order. We are now come to the first case of the reverse problem, which is, to find the primitive equation belonging to a fluxional equation of the first order, containing two indeterminate quantities.

168. It has been shown, (Art. 49,) that, in deducing from a primitive equation its fluxional equation of the first order, we can always exterminate any one of the constant quantities contained in the primitive equation; therefore, that this last may have the most general form possible, it ought always to contain a constant but arbitrary quantity, that does not appear in the fluxional equation.

169. Every fluxional equation, which involves only the simplest powers of \( dx \) and \( dy \), has this form, \( M \frac{dx}{dx} + N \frac{dy}{dy} = 0 \), \( M \) and \( N \) being supposed functions of any two variable quantities \( x \) and \( y \); and it expresses a certain relation between the variable quantity \( x \), its function \( y \), and the fluxional co-efficient \( \frac{dy}{dx} \). The method which analysts first thought of employing, to discover the primitive equation, was to separate the variable quantities, so as to give it, if possible, the form \( X \frac{dx}{dx} + Y \frac{dy}{dy} = 0 \), \( X \) being a function of \( x \) alone, and \( Y \) a function of \( y \) alone. The primitive equation was then \( \int X \frac{dx}{dx} + \int Y \frac{dy}{dy} = c \), and hence \( c \) is some constant quantity.

For example, let the fluxional equation be

\[
m \frac{dx}{dx} + n \frac{dy}{dy} = 0;
\]

divide the terms by \( xy \), and it becomes

\[
\frac{mdx}{x} + \frac{n dy}{y} = 0.
\]

Hence, taking the fluents of the terms, we find

\[
m (y x^n + n y x^m) = (c), \text{or } n (x^m + y^n) = (c);
\]

and passing from logarithms to numbers,

\[
x^m y^n = c;
\]

and this is the primitive equation.

170. The variable quantities may always be separated, when the fluxional equation is homogeneous. In this case, the equation \( M \frac{dx}{dx} + N \frac{dy}{dy} = 0 \) has the form

\[
(A y^k x^h + B y^k + n x^h + n + \text{&c.}) \frac{dx}{dx} + (D y^k + P x^k + \text{&c.}) \frac{dy}{dy} = 0,
\]

the sum of the exponents in each term being \( k + k \). Put \( m = h + k \), then, dividing all the terms by \( x^m \), any term as \( A y^k x^h \) becomes \( \Lambda (y x)^k \), thus \( M \) and \( N \) become functions of \( \frac{y}{x} \); so that if we divide the equation

\[
M \frac{dx}{dx} + N \frac{dy}{dy} = 0 \text{ by } M, \text{ and the fraction } \frac{N}{M} \text{ by } x^m,
\]

and put \( y = xz \), this fraction will be a function of \( z \) alone. Let \( Z \) be that function, then the equation becomes \( dy + Zd x = 0 \); but \( y = xz \) gives \( d y = x d x + z d x \), therefore, \( x \frac{d x}{x} + (z + Z) \frac{d z}{z} = 0 \), and hence

\[
\frac{dx}{x} + \frac{dz}{z + Z} = 0, \text{ and } \log x + \int \frac{dz}{z + Z} = c.
\]

**Example 1.** Let \((a x + b y) \frac{dy}{dy} + (f x + g y) \frac{dx}{dx} = 0.\)
FLUXIONS.

Divide by $ax+by$, and put $z$ for $x$ instead of $y$, and the equation becomes

$$d y + \frac{f + g z}{a + b z} d z = 0;$$

instead of $d y$ put now $z d x + x d z$, and the equation is transformed to

$$\frac{d x}{x} + \frac{(a + b z) d z}{b z^2 + (a + b z) z + 1} = 0.$$  

The fluents of the two parts of this equation may now easily be found. As a particular case, let $y d y + (x^2 + y^2) d x = 0$; then, because $a = 0$, $b = i$, $x = 2$, we have

$$\frac{d x}{x} + \frac{z d z}{z^2 + 2 z + 1} = 0.$$  

This is easily transformed to

$$\frac{d x}{x} + \frac{d z}{1 + z} = \frac{d z}{(1 + z)^2} = 0,$$

and hence, taking the fluents,

1. $c (x + z) + 1 + \frac{1}{1 + z} = 0.$

or 1. $c (x + z) = \frac{1}{1 + z}$

or 1. $c (x + y) = x + y.$

Ex. 3. Let $x d y - y d x = x d x + y \sqrt{(x^2 + y^2)}$; we divide by $x$, and have $d y - \frac{y}{x} d x = d x + \sqrt{(1 + \frac{y^2}{x^2})}$; and making $y = x z$, so that $d y = z d x + x d z$, we have

$$\frac{d x}{x} = \frac{d z}{\sqrt{1 + z^2}}.$$  

hence (art. 192.) $x = c z + c \sqrt{(1 + z^2)}$, or $x^2 = c y + c \sqrt{(x^2 + y^2)}$, which, by transposing $c y$ and taking the squares, becomes $x^2 = c^2 y + c^2 z^2.$

170. In some cases an equation may be rendered homogeneous by transformation. Thus, in the equation

$$(a x + b y + c) d y + (m x + n y + p) d x = 0,$$

we make $(a x + b y + c) = z$, $m x + n y + p = t$,

hence $a d x + b d y = d z$, $m d x + n d y = d t,$

and $d y = \frac{m d z - a d t}{m b - n a}, d x = \frac{b d t - n d z}{m b - n a}.$

The proposed equation now becomes $d z + t d x = 0$, or $(m z + n t) d z + (b t - a z) d t = 0$, which is homogeneous.

If $m b - n a = 0$, this transformation fails; but then, $m = \frac{na}{b}$, and the proposed equation is

$$b d y + b p d x + (a x + b y) (b d y + n d x) = 0,$$

the variable quantities may now be separated by making $a x + b y = z$, by which $d y = \frac{d z - a d x}{b}$. The equation then becomes

$$d x = \frac{(c + z) d z}{a c - b p + (a - n) z}.$$  

171. Let us now consider the equation

$$d y + P y d x = Q d x,$$

in which $P$ and $Q$ are functions of $x$ alone. This equation has been called linear, but with more propriety, a fluxional equation of the first degree, and of the first order. We make $y = z t$; by this substitution the equation becomes

$$z d t + d t + P z d x = Q d x;$$

as we may make any assumption we please respecting one of the indeterminate quantities $z, t$, we may suppose that the coefficient of $z$ is $0$; by this we get

$$d t + P d x = 0;$$

$d t + P d x = 0$, and hence

1. $1. (t) = - P d x$; and as $P d x$ does not contain $y$, its fluent may always be found. Let us denote it by $u$, then we have 1. $(t) = u + a, (a$ being a constant quantity) and $t = e^{-u + a} = e^{-u} e^a = \Lambda e^{-u}$; here $e$ is the number of which Nap. log. $= 1$, and $\Lambda$ is put for the constant quantity $e^a$. We now substitute this value of $t$ in the equation $t d x = Q d x$, and we have

$$\Lambda d z = Q e^{-u} d x,$$

and hence

$$\Lambda z = \int Q e^{-u} d x + c.$$  

Now $Q$ and $u$ are known functions of $x$, and the fluent $\int Q e^{-u} d x$ being found, we put for $\Lambda z$ its value $\Lambda y$, or $y e^u$, and at last we find

$$y e^u = \int Q e^{-u} d x + c,$$ where $u = \int P d x.$

From this expression we may infer that it was not necessary to add the constant quantity $a$ to the fluent $\int P d x = u$, as it has disappeared again in the subsequent part of the calculus.

Example. Let the equation be $y d y + y d x = - a x d x$; then $P = 1, Q = a x, u = \int P d x = x$,

$$\int Q e^{-u} d x = \int a x e^{-x} d x = a e^{-x} (x^3 - 3 x^2 + 6 x - 6),$$

therefore $y = c e^{-x} + a (x^3 - 3 x^2 + 6 x - 6).$

172. The early analysts classed fluxional equations by the number of their terms. In such as consisted of two terms, and which therefore had the form $\mu u \dot{z} d z = z \mu d u$, the variable quantities could be immediately separated; it was not so however of equations consisting of three terms comprehended in the formula

$$\gamma u i \dot{z} d z + \beta u \dot{z} k d u = \alpha u \dot{z} f d u.$$

This may be put under a more simple form by dividing all the terms by $\gamma u i \dot{z} f$, it then becomes

$$z k f d z + \beta u \dot{z} i = z k f d u = u \dot{z} i,$$

$$\gamma$$

Suppose now $z k f d z = \frac{d y}{g - i + 1} d u = u \dot{z} i + 1,$

then $z k f + 1 = y u \dot{z} i + 1 = z$, and

$$d y + \frac{(k - f + 1) \beta}{g - i + 1} d u = u \dot{z} i + 1.$$  

In order to abridge, make

$$\frac{(k - f + 1) \beta}{g - i + 1} = b, \frac{(k - f + 1) a}{g - i + 1} = a, \frac{(k - f + 1) \alpha}{g - i + 1} = a.$$
FLUXIONS.

174. In general, let \( u \) be any function of two variable quantities \( x \) and \( y \), then, whether these be regarded as independent of each other, or the one as a function of the other, we have \( \frac{du}{dx} = \frac{du}{dy} \frac{dy}{dx} \) (art. 103.) in this expression \( \frac{du}{dx} \) means the fluxional coefficient of the function \( u \), taken as if \( x \) were the only variable quantity contained in the function, \( y \) being of course considered as constant; and \( \frac{du}{dy} \) is to be understood in a similar sense in regard to \( x \) (art. 100.) Put \( \frac{du}{dx} = M, \frac{du}{dy} = N \), then, \( d u = M \, dx + N \, dy \); now, it has been proved (art. 102.) that \( \frac{d}{dx} \left( \frac{M}{N} \right) \) therefore

\[
\frac{dM}{dy} = \frac{dN}{dx}.
\]

Hence we may conclude, that if \( M \) and \( N \) are such functions of two variable quantities \( x \) and \( y \) that \( M \, dx + N \, dy \) is a complete fluxion, the condition expressed by the equation (1) will always be satisfied.

On the contrary, if \( M \) and \( N \) are such functions of \( x \) and \( y \), that \( \frac{dM}{dy} = \frac{dN}{dx} \), then \( M \, dx + N \, dy \) shall be an exact fluxion, which may in every case be found.

To prove the second part of the proposition, let us suppose the fluent of \( M \, dx \) to be taken upon the hypothesis, that in the function \( M \), \( x \) is variable, and \( y \) constant; and let the fluent be \( P+Y \), where \( Y \) is any function whatever of \( y \), which serves as the constant correction of the fluent, and \( P \) is a known function of \( x \) and \( y \), which results from \( \int M \, dx \) relatively to \( x \) only, so that \( M = \frac{dP}{dx} \). The complete fluxion of \( P+Y \) is

\[
\frac{dP}{dx} \, dx + \frac{dP}{dy} \, dy + dY \quad (103 \text{.}) \quad \text{or} \quad M \, dx + \frac{dP}{dy} \, dy + dY; \]

by comparing this with \( M \, dx + N \, dy \), we see that the two expressions will be identical, if we can give such a value to \( Y \), that \( N \, dy = \frac{dP}{dy} \, dy \), or

\[
\frac{dY}{dy} = \left( N - \frac{dP}{dy} \right) \, dy \quad (2)
\]

and then the fluent of \( M \, dx + N \, dy \) will be \( P+Y \).

Now, by taking the fluxion of \( M = \frac{dP}{dx} \) in respect of \( y \), we have \( \frac{dM}{dy} = \frac{dP}{dx} \), but by hypothesis \( \frac{dM}{dy} = \frac{dN}{dx} \) and \( \frac{dP}{dy} = \frac{dP}{dx} \) (102.), therefore \( \frac{dN}{dx} = \frac{dP}{dx} \) and \( \frac{dN}{dy} = \frac{dP}{dy} \); that is \( d \left( N - \frac{dP}{dy} \right) = 0 \), the fluxion being taken, supposing \( x \) alone variable; therefore \( N = \frac{dP}{dx} \) is constant in respect of \( x \), so that it is a function of \( y \) only; hence the possibility of finding \( Y = \int \left( N - \frac{dP}{dy} \right) \, dy \) is proved, and we have the
Let $\frac{dM}{dx} + \frac{dN}{dy}$ expressed by $P + \int (N \frac{dP}{dy}) dy$, and hence, $P = \int dM dx$, the fluent being taken upon the supposition that $y$ is constant.

It is evident that we may begin with taking the fluent of $N dy$, supposing that $x$ is constant, and proceed in all respects as we have explained above. In general, we ought to begin with that term which brings out the fluent with the least calculation.

**Example 1.** Let $2 b x d x + \int \frac{dP}{y} \sqrt{(1 + y^2)} + a dy = 0$.

In this case $M = 2 b x$, $N = \frac{\sqrt{(1 + y^2)}}{y}$, and hence $d M = 0$, $d N = 0$; as the condition expressed by the equation (1.) is satisfied, the expression $2 b x d x + \int \frac{dP}{y} \sqrt{(1 + y^2)} + a dy$ is an exact fluent. To determine the fluent, we have $P = \int M dx = 2 b x^3$, $\frac{dP}{dy} = 0$,

$$\int (N \frac{dP}{dy}) dy = \int \left( \frac{a y + \sqrt{(1 + y^2)}}{y} \right) dy = ay + 1 \left\{ cy + c \sqrt{(1 + y^2)} \right\}.$$

Hence the primitive equation is

$$b x^3 + ay + 1 \left\{ cy + c \sqrt{(1 + y^2)} \right\} = 0.$$

**Ex. 2.** Let the fluxional equation be

$$a (x d x + y dy) + y d x - x d y = \frac{a x}{\sqrt{(x^2 + y^2)}} - \frac{ay}{x} \sqrt{x^2 + y^2} + 3 b y^3 dy = 0;$$

in this case $M = \frac{a x}{\sqrt{(x^2 + y^2)}}$, $N = \frac{ay}{x} \sqrt{x^2 + y^2} + 3 b y^3$.

These expressions for $M$ and $N$ satisfy the condition $d M = \frac{dN}{dx}$, (we omit the calculation for the sake of brevity,) therefore the expression which is put $= 0$, is an exact fluent; to determine it, we have

$$P = \int a x d x + \int \frac{y d x}{\sqrt{x^2 + y^2}} = ay \sqrt{x^2 + y^2} + \arctan \left( \frac{x}{y} \right),$$

the fluents being taken upon the hypothesis that $y$ is constant,

$$\frac{dP}{dy} = \frac{ay}{\sqrt{x^2 + y^2}} - \frac{x}{x^2 + y^2}, N = -\frac{dP}{dy} = 3 b y^3,$$

$$\int (N \frac{dP}{dy}) dy = \int 3 b y^3 dy = b y^4 + c.$$ The fluent is therefore

$$a \sqrt{(x^2 + y^2)} + \arctan \left( \frac{x}{y} \right) + b y^4 + c = 0.$$

**Ex. 3.** Let the fluxional equation be

$$\frac{y d y}{\sqrt{(x^2 + y^2)}} + dx = 1 + \frac{x}{\sqrt{(x^2 + y^2)}} = 0;$$

Here $N = \frac{y}{\sqrt{x^2 + y^2}}$, $M = 1 + \frac{x}{\sqrt{(x^2 + y^2)}}$,

$$\frac{dM}{dy} = -\frac{xy}{(x^2 + y^2)^{3/2}}, \frac{dN}{dx} = -\frac{xy}{(x^2 + y^2)^{3/2}},$$

Hence it appears that the first member of the equation is an exact fluxion, and, proceeding as in last example, we find

$$x + \sqrt{(x^2 + y^2)} = c.$$

175. If, in the equation $M d x + N d y = 0$, the condition $\frac{dM}{dy} = \frac{dN}{dx}$ (which is called the condition of integrability,) is not satisfied, we may next inquire whether it is possible to find some factor, a function of $x$ and $y$, by which, when the expression $M d x + N d y$ is multiplied, it may become a complete fluxion. Let

the fluxional equation be put under this form $\frac{dy}{dx} + K = 0$; therefore

$$\frac{dy}{dx} + K = \frac{dy}{dx} + \frac{P}{Q} = \frac{P dx + Q dy}{Q dx},$$

that is, $dy/dx + K = \frac{du}{Q dx}$; and hence

$$Q (dy + K dx) = du.$$ Now, the second member is a complete fluxion, therefore the first member is also a complete fluxion; hence it appears, that there always exists a factor $Q$, by which, if the fluxional equation $dy + K dx = 0$ be multiplied, the result will be a complete fluxion.

Let both sides of this last equation be multiplied by $U$, any function whatever of $u$, then we have

$$UQ (dy + K dx) = U du.$$ Now, $U du$ is still a complete fluxion; therefore the other member of the equation will also be a complete fluxion; and as the factor $UQ$ may have an infinite variety of forms, it appears that there is an infinite number of factors, such, that if a fluxional equation be multiplied by any one of them, it will be rendered a complete fluxion.

176. It appears now, that the whole difficulty of resolving a fluxional equation is reduced to the determination of a factor which may render it integrable. This, however, in general, is a problem of insuperable difficulty. It can be resolved when the equation is homogeneous, and also when it has the form $dy + P y dx = Q dx$, $P$ and $Q$ being any functions of $x$; but we have seen, that in these cases a solution may be obtained by other means. When the primitive equation is known, the factor can be found by which the primitive might have been deduced from its fluxional equation; but then it is of no use. Euler, after having shown that, in certain cases, the factor may be found, inverts the problem, and inquires what fluxional equations may be rendered integrable by factors of a given form. On this subject we must refer to his *Instit. Cal. Int.* vol. i. sect. 2., or Lacroix, *Traite du Cal. Diff.* &c. 2d part, chap. 4.
177. Let $M$ be any function of two quantities $x, y,$ and let $u = \int M \, dx$, the fluent being supposed taken upon the hypothesis that $x$ is variable and $y$ constant; it is sometimes necessary to find the fluxional co-efficient of $u$ relatively to $y,$ or in other words, to find the fluxion of $\int M \, dx$ relatively to $y,$ without previously finding the fluxion of the expression in respect of $x$. Because $u = \int M \, dx$, therefore \( \frac{du}{dx} = M \), but \( \frac{d^2 u}{dy \, dx} = \frac{dM}{dy} \), therefore \( \frac{du}{dy} \) of $x$ and \( \frac{d^2 u}{dxdy} \), therefore \( \frac{du}{dy} \), and \( \frac{d^2 u}{dxdy} \) being the fluent relatively to $x$, considering now $y$ as constant, \( \frac{du}{dy} = \int \frac{dM}{dy} \, dx \).

Ex. Let $u = \int \sqrt{y^2 - x^2} \, dx$, here $M = \sqrt{y^2 - x^2}$, and \( \frac{dM}{dy} = \frac{x^2}{(y^2 - x^2)^{1/2}} \), and \( \frac{d^2 M}{dy \, dx} = \frac{1}{y} - \frac{x^2}{(y^2 - x^2)^{3/2}} \).

The theorem expressed by the formula \( \frac{du}{dy} = \int \frac{dM}{dy} \, dx \) will apply to the calculation of \( \frac{dP}{dy} \) in art. 174, without previously taking the fluent $P = \int M \, dx$. It was invented by Leibnitz, and was considered an important discovery in the calculus. (See Bossut Traité du Cal. Diff. &c. vol. ii. p. 58.) The whole fluxion of $u$ relatively to both $x$ and $y$ will be

\[ M \, dx + \left\{ \int \frac{dM}{dy} \, dx \right\} \, dy. \]

Observing that the fluent in the parenthesis is to be taken, supposing $x$ alone to be variable.

178. When a fluxional equation involves the second or higher powers of $dx$ and $dy$, as in this example

\[ dy^2 - a^2 \, dx^2 = 0, \]

we may find the value of \( \frac{dy}{dx} \) by resolving an algebraic equation. In the present case, \( \frac{dy}{dx} = \pm a, \) so that $dy + adx = 0,$ and also $dy - adx = 0$; hence $y + ax + c = 0,$ and $y - ax + c' = 0,$ are two primitive equations, from either of which the fluxional equation may be derived, and also from their product

\[(y + ax + c) (y - ax + c') = 0.\]

179. When the equation contains only one of the variable quantities, $x$ for example, we may deduce from it \( \frac{dy}{dx} = X, \) a function of $x$; and hence $y = f(X \, dx)$. But if it be more easy to resolve the equation in respect of $x$, then putting \( x = P, \) we may find $x = P,$ some function of $p$, and hence $dx = dP$; and since $dy = p \, dx$, therefore, $dy = p \, dP$, and $y = \int p \, dP = P - \int P \, dP$.

The relation between $x$ and $y$ is now to be found by eliminating $p$, by means of the two equations

\[ x = P, \quad y = P - \int P \, dP. \]

Let the equation be $\frac{dy}{dx} + a \, dy = 0 \sqrt{(dx^2 + dy^2)}$; making \( p = \frac{dy}{dx}, \) we have $x = \sqrt{a^2 + b^2 - \sqrt{a^2 + b^2}}$, and $y = \sqrt{a^2 + b^2 - \sqrt{a^2 + b^2}}$. The fluent of $d \, p \sqrt{(1 + P^2)}$ may be found by art. 123.

180. When the primitive equation cannot be deduced from a fluxional equation by any of the known artifices of analysis, then, as a last resource, recourse must be had to approximation by infinite series.

Ex. Let the fluxional equation be $dy + y \, dx = m \, x^2 \, dx$; and let us suppose it to be known that when $x = a$, then $y = b$. Assume $x = a + t$, and $y = b + u$; then when $t = 0$ we have $u = 0$; we have also $dx = dt$ and $dy = du$; by these, the proposed equation is transformed to

\[ du + (b + u) \, dt = m(a + t)^n \, dt. \]

We next assume

\[ u = A \, t^a + B \, t^{a+1} + C \, t^{a+2} + \&c. \]

\[ a, \, A, \, B, \, C, \, \&c. \quad \text{being indeterminate quantities which are to be investigated.} \]

From this assumption, $u = A \, t^a + B \, t^{a+1} + C \, t^{a+2} + \&c.$

The terms of the equation being now brought all to one side and put $u = 0$, and these expressions for $u$ and $du$ being substituted in it, we have

\[ A \, t^{a-1} + (a+1)B \, t^a + (a+2)C \, t^{a+1} + \&c. \]

\[ + b + A \, t^a + B \, t^{a+1} + C \, t^{a+2} + \&c. = 0. \]

If we suppose $a = 1$, the terms placed vertically become similar, and then putting the coefficients of like-powers of $t = 0$ agreeably to the theory of indeterminate coefficients, there results

\[ A + b - m \, a^s = 0, \quad 2 \, B + A - mna^{s-1} = 0, \]

\[ 3 \, C + B - m(n-1) \, a^{s-2} = 0, \quad \&c. \]

Hence $A = ma^s - b$.

\[ B = \frac{mn(n-1)a^{s-1} - mna^{s-1} + ma^{s-2}}{2}, \quad \&c. \]

These values being substituted in the series, we have $u$ expressed by $t$ and known quantities; we may then put $x = a$ for $t$, and $y = b$ for $u$, and the result will give the relation between $x$ and $y$.

We might have proceeded with the original equation $dy + y \, dx = m \, x^2 \, dx$ exactly as we have done with the transformed equation, assuming $y = A \, x^s + B \, x^{s+1} + \&c.$ But as the result would not have contained a constant correction, it would only have given the relation of $y$ and $x$ upon the hypothesis that $y = 0$, when $x = 0$. The transformation serves to introduce the constant correction.

181. In the assumed series $u = \int M \, dx + B \, x^{s+1} + \&c.$ the exponents of $t$ form an arithmetical progression, of which the common difference is 1. In many cases, however, the common difference will be a fraction, as in this example $(d \, x + d \, y) \, y = d \, x$; here we may assume...
FLUXIONS.

Of Fluxional Equations of the Second and Higher Orders.

182. Let \( f(x, y, c, c') \) denote any function, or expression composed of the variable quantities \( x, y \), and two constant quantities \( c, c' \), besides any other constant quantities. Then

\[
f'(x, y, \frac{dy}{dx}, c, c') = 0. \tag{1}
\]

may represent any primitive equation. By taking the fluxion, (as explained Art. 44—50), we obtain its fluxional equation of the first order, which will contain \( \frac{dy}{dx} \) in addition to the other quantities, and may be expressed thus,

\[
f''(x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, c, c') = 0. \tag{2}
\]

By taking the fluxions a second time, an equation will result, involving the fluxional co-efficient of the second order \( \frac{d^2y}{dx^2} \), which may be expressed thus,

\[
f'''(x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \frac{d^3y}{dx^3}, c, c') = 0. \tag{3}
\]

As these three equations will all hold true at once, we may exterminate the two constant quantities \( c, c' \), and the result will be a single equation

\[
F(x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}) = 0, \tag{4}
\]

in which the quantities \( c, c' \) are not found. This will be the fluxional equation of the second order corresponding to the primitive (1), and which is independent of the constant quantities \( c, c' \).

We may arrive at the very same equation (4) in two other ways.

1. We may give the primitive (1) these two forms,

\[
\phi(x, y, c) = 0, \quad \psi(x, y, c') = 0.
\]

Here \( \phi \) and \( \psi \) are symbols, which serve the same purpose as \( f, f', f'', \) &c. Taking the fluxions of these equations, \( c' \) is not found in the result of the first, nor \( c \) in the result of the second. These results may therefore be put under the form

\[
\phi'(x, y, \frac{dy}{dx}) = 0, \quad \psi'(x, y, \frac{dy}{dx}) = c'.
\]

By taking now the fluxions of these equations, we shall derive the very same equation from each, which will be identical with equation (4).

For example, let the primitive equation be

\[
x^3 - 2a x + 2by = 0;
\]

here \( a \) and \( b \) may represent the constant quantities \( c, c' \) in equation (1); by taking the fluxions, regarding \( dx \) as constant, we find,

\[
x^2 - a + c, \quad \frac{dy}{dx} = b.
\]

After eliminating \( a \) and \( b \) by these three equations, we get

\[
2y - 2x \frac{dy}{dx} + x^3 \frac{d^2y}{dx^2} = 0,
\]

a fluxional equation of the second order, of which the complete primitive equation is \( x^3 - 2a x + 2by = 0 \).

We may otherwise put the primitive equation under these forms

\[
\frac{x^3}{x} + 2b y = 2a, \quad \frac{x^3 - 2a x}{y} = -2b.
\]

Taking the fluxions, and arranging the results, so that the constant quantities may stand alone, we have

\[
\frac{x^3}{x} = 2b, \quad 2x y - x^2 \frac{dy}{dx} = 2a.
\]

By taking the fluxion of either of these equations, the constant quantity in the second member disappears, and we find \( 2y - 2x \frac{dy}{dx} + x^3 \frac{d^2y}{dx^2} = 0 \), the same as before.

183. As two of the constant quantities contained in a primitive equation may not be found in the fluxional equation of the second order, which is derived from it, so, on the other hand, in returning from a fluxional equation of the second order, to its absolute primitive, the latter cannot be complete unless it contain two arbitrary constant quantities, which are not in the former. Moreover, as the same fluxional equation of the second order may be derived from two distinct fluxional equations of the first order, every fluxional equation of the second order has two primitive equations of the first order, each containing its own arbitrary constant quantity, and these again have one and the same absolute primitive equation, which is also the complete primitive, belonging to the fluxional equation of the second order. The properties of fluxional equations of the third and higher orders are perfectly analogous to these. See Lagrange Leçons sur le Calcul des Fonctions, Leçon xii.

184. The most simple fluxional equation of the second order is \( \frac{d^2y}{dx^2} = X \), some function of \( x \), or \( \frac{d^2y}{dx^2} = X d x \). Let us suppose that \( P \) is the variable part of the fluent of \( X d x \), then taking the fluent of both members of the equation, and considering that, in the first member, \( d x \) in the denominator is constant, we have

\[
\frac{dy}{dx} = \int X d x = P + c, \quad \text{and} \quad dy = P d x + c d x.
\]

Taking now the fluents a second time,

\[
y = \int P d x + c x + c'.
\]
As \( \int P \ dx = \int x \ dx - \int x \ dx \), therefore, \( y = z \int x \ dx - \int x \ dx + c \).

Here \( c \) and \( c' \) are the two constant corrections that complete the primitive equation. For example, if \( dy = -ax \ dx + c \), then, \( y = \frac{1}{2} ax^2 + c \), and \( \frac{dy}{dx} = c' \).

In the very same way, the primitive of the fluxional equation \( dy = -X \ dx \) is found; we first put it under the form \( \frac{dy}{dx} = X \ dx \), then we have \( \frac{dy}{dx} = \int X \ dx \).

The equation is now of the second order; therefore the rest of the operation is the same as has been explained. The primitive will contain three constant corrections: a like fluxional equation of the fourth order would contain four, and so on.

185. When a fluxional equation of the second order contains only \( \frac{dy}{dx} \) and \( \frac{d^2y}{dx^2} \) and constant quantities, if we put \( \frac{dy}{dx} = p \), then, \( dx \) being regarded constant, \( \frac{d^2y}{dx^2} = \frac{dp}{dx} \); the equation will now involve \( p, dp, dx \), and constant quantities, and it will be of the first order in respect of \( p \) and \( x \); we may therefore find \( dx = \int P \ dx \), \( P \) being put for some function of \( p \); and since \( dy = \int P' \ dx \), we have 
\[
x = \int P \ dx, \quad y = \int P \ dx.
\]

These fluents being taken, and a constant quantity added to each, by eliminating \( p \), we shall get an equation expressing the relation between \( x \) and \( y \).

Ex. Let \( a \left[ \frac{dy}{dx} \right]^2 + \left( \frac{d^2y}{dx^2} \right)^2 = 0 \); when \( p \) is put for \( \frac{dy}{dx} \) and \( \frac{dp}{dx} \) for \( \frac{d^2y}{dx^2} \), this equation becomes \( a \frac{dp}{dx} + (1 + p^2)^{\frac{3}{2}} = 0 \).

Hence \( dx = \frac{dp}{(1 + p^2)^{\frac{3}{2}}} \), \( dy = \frac{-a dp}{(1 + p^2)^{\frac{3}{2}}} \), and taking the fluents 
\[
x = c - \frac{a p}{\sqrt{1 + p^2}}, \quad y = c' + \frac{a}{\sqrt{1 + p^2}}.
\]

These form the proposed fluxional equation under this form 
\[
a = - \frac{(dx + dy)^{\frac{3}{2}}}{dx}.\]

As the first member of the proposed fluxional equation expresses the radius of curvature of any curve, its primitive equation expresses the nature of a curve whose radius of curvature is a given function of the abscissa.

186. Let us next consider equations of the form 
\[
\frac{dy}{dx} = Y, \quad \text{some function of } y.
\]

Putting as before \( \frac{dy}{dx} = p \), we have \( \frac{dy}{dx} = \frac{dp}{dx} \); hence the proposed equation becomes, after substitution, \( \frac{dp}{dx} = Y, \) and 
\[
p \ dp = Y \ dy, \quad \text{and} \quad p^2 = 2 \int Y \ dy + c, \quad\text{therefore} \quad p = \sqrt{\frac{dy}{dx}}.
\]

187. When the equation contains \( \frac{dy}{dx} = \frac{dy}{dx} \) and \( x \), it may be transformed to a fluxional equation of the first order, by substituting \( p \ dx \) for \( dy \), and \( d p \ dx \) for \( d^2y \); then, if we can find the primitive of that fluxional equation, and thence the value of \( p \) in terms of \( x \), we may have the value of \( y \) from the formula \( y = \int p \ dx \), or else, if we have the value of \( x \) in terms of \( p \), then because \( \int p \ dx = p x - \int x \ dp \), we shall have 
\[
y = p x - \int x \ dp.
\]

Ex. Suppose the equation to be 
\[
\frac{(dx + dy)^{\frac{3}{2}}}{dx} = X, \quad \text{or} \quad \frac{(1 + p^2)^{\frac{3}{2}}}{dp} = X,
\]

where \( X \) denotes some function of \( y \). Then 
\[
\frac{dy}{dx} = \frac{-dp}{X(1 + p^2)^{\frac{3}{2}}} \text{ and } \int \frac{dx}{X} = \frac{-p}{(1 + p^2)^{\frac{3}{2}}}.
\]

Let \( V \) represent \( \int \frac{dx}{V(1 - V)} \), then 
\[
p = \frac{V}{\sqrt{(1 - V^2)}} \text{ and } y = \int \frac{V \ dx}{\sqrt{(1 - V^2)}}.
\]

As the first member of the proposed fluxional equation expresses the radius of curvature of any curve, its primitive equation expresses the nature of a curve whose radius of curvature is a given function of the abscissa.

188. If the fluxional relation contain \( \frac{dy}{dx} = \frac{dy}{dx} \) and \( y \), we may, as before, put \( p = \frac{dy}{dx} \), from which we get 
\[
\frac{dy}{dx} = \frac{dp}{dx} = \frac{p \ dp}{dy}, \quad \text{the equation will now involve} \quad p \ dp, \ dy, \ p, \text{and } y \text{ only. When the primitive equation can be found, and thence the value of } p \text{ in terms of } y, \text{ we may find } x \text{ by the formula } x = \int \frac{dy}{p} \text{; but when } y \text{ is expressed by } p, \text{ we may then employ the formula}\n\]
\[
x = \frac{y}{p} + \int \frac{y \ dp}{p^2}.
\]

189. In fluxional equations of the first order, it is the same thing whether \( y \) be considered as a function of \( x \), or \( x \) as a function of \( y \). Either hypothesis leads to the same primitive equation. In fluxional equations of the second order, however, it must always be under-
stood which of the two is the independent variable quantity, because it is the fluxion of this quantity that is considered as constant, or that serves as an unit to measure the fluxion of the other quantity. We have supposed $y$ to be a function of $x$, so that $d\,x$ is considered as constant, but to pass from the hypothesis of $y$ a function of $x$, to that of $x$ a function of $y$; and, consequently, from the hypothesis of $d\,x$ constant, and $d\,y$ variable, to that of $d\,y$ constant, and $d\,x$ variable, it is only necessary to have recourse to the formulæ of art. 96, and put \( -\frac{dy}{dx} \cdot \frac{d\,y}{d\,x} \) for \( \frac{d^2y}{dx^2} \). A similar remark may be made respecting the fluxions of any order whatever.

Or, instead of regarding $x$ and $y$ as functions the one of the other, they may be referred to some other variable quantity $t$, by means of the formulæ above quoted.

**Example.** Let the equation be \( (a+b) \frac{d^2y}{dx^2} + \frac{dy}{dx} + Q \frac{dy}{dt} + Qy = 0 \), P, Q, and R, being any functions of $x$, are called **linear**, because $y$ is only of one dimension; they are also said to be of the **first degree**.

It may be easily supposed, that the difficulty of finding the primitive equation will be greater than in the like equation of the first order, and indeed, except in particular cases, there are no known methods of reducing the problem to the finding of the fluxion of a single variable quantity, that is, to the quadrature of curves.

If $R = 0$, in which case the equation is

\[
\frac{d^2y}{dx^2} + P \frac{dy}{dx} + Qy = 0,
\]

it may be reduced to a fluxional equation of the first order by a very simple transformation. Putting $c$ for the number of which the Nap. log. = 1, assume $y = e^{\int u \, dx}$, then, taking the fluxions, by art. 26. rule (C), considering $d\,x$ as constant,

\[
dy = u \, dx \, e^{\int u \, dx}, \quad d^2y = e^{\int u \, dx} (d\,u \, dx + u^2 \, d\,x^2).
\]

The values of $d\,y$ and $d^2\,y$ being substituted in the equation, and the common factors rejected, it becomes

\[
du + (u^2 + Pu + Q) \, dx = 0.
\]

If $P$ and $Q$ were constant quantities, $u$ might have been supposed a constant quantity, we then have $d\,u = 0$, and to determine $u$ we have

\[
u^2 + Pu + Q = 0.
\]

Let $a$ and $b$ be the roots of this quadratic equation; then $u = a$ and $u = b$, and hence these two values of $y$,

\[
y = e^{ax + c}, \quad y = e^{bx + c},
\]

or putting $C$ for $e^c$, and $C'$ for $e^{c'}$,

\[
y = C e^{ax}, \quad y = C' e^{bx}.
\]

These, however, are only **particular** values of the function $y$, because each contains only a single arbitrary constant quantity, but by adding them we get

\[
y = Ce^{ax} + C'e^{bx},
\]

for the complete primitive equation. To prove this, by taking the fluxions we get

\[
\frac{dy}{dx} = aCe^{ax} + bC'e^{bx}, \quad \frac{d^2y}{dx^2} = a^2Ce^{ax} + b^2C'e^{bx}.
\]

From these, and the primitive equation, after eliminating $C$ and $C'$, we have

\[
\frac{d^2y}{dx^2} + \left(a + b\right) \frac{dy}{dx} - aby = 0.
\]

This will agree with the proposed equation, if we give $a$ and $b$ such values, that $a + b = P$, and $ab = -Q$. If $a$ and $b$ come out impossible quantities, then the exponents of $e$, in the value of $y$, will have the form $a + \beta \sqrt{-1}$, but then the exponential $e^{\beta \sqrt{-1}}$ may be expressed by circular functions. Art. 123, and **Arithmetic of Sines**.

191. When $P$ and $Q$ are variable quantities, functions of $x$, then $v$ and $v'$ are two values of $y$, which each satisfy the equation \( \frac{d^2y}{dx^2} + P \frac{dy}{dx} + Qy = 0 \), we may take

\[
y = C + C'v,
\]

for the complete primitive equation. For then $dy = C + C'v$, $d^2y = C + C'v$, and the fluxional equation becomes

\[
C' \left(\frac{d^2v}{dx^2} + P \frac{dv}{dx} + Qv\right) + C' \left(\frac{dv'}{dx} + P \frac{dv'}{dx} + Qv'\right) = 0.
\]

Now by hypothesis

\[
\frac{d^2v}{dx^2} + P \frac{dv}{dx} + Qv = 0, \quad \frac{dv'}{dx} + P \frac{dv'}{dx} + Qv' = 0,
\]

therefore the equation is identical, and so the value of $y$ is truly determined.

The property which we have shown to belong to a linear equation of the second order applies to linear equations of all orders whatever. See Lagrange Théorie des Fonct. Anal. 65—70.

192. As an example of the manner of resolving a fluxional equation of the second order by approximation, let the equation be

\[
d^2y + a\,x^2 \, y \, dx^2 = 0.
\]

Let us suppose that

\[
y = x^\lambda (A + Bx^{n+2} + Cx^{2n+4} + Dx^{3n+6} + &c.),
\]

thence we deduce

\[
\lambda (\lambda - 1)A x^{\lambda - 2} + (\lambda + n + 2)(\lambda + n + 1)B x^{\lambda + n} + &c.
\]

\[
a x^n y = \frac{\lambda (\lambda - 1)A}{\lambda + n},
\]

Hence, after substituting in the proposed equation, we get

\[
\lambda (\lambda - 1)A x = 0,
\]

\[
(\lambda + n + 2)(\lambda + n + 1)B + \Lambda a = 0, &c.
\]

The first equation ought to leave $\Lambda$ indeterminate, as one of the two constant corrections that enter into the value of $y$; that this may be the case, we must have $\lambda = 0$, or $\lambda = 1$. First, suppose $\lambda = 0$, then,
of $v$ and $z$, then, by the principles of the projection, 

$$z' = r \frac{d\theta}{\cos \theta},$$

therefore, putting the ratio of the fluxions

$$\frac{dz}{dv} = \frac{1}{\cos \theta},$$

and $dz = dv$. Therefore, taking the fluent (art. 146),

$$z = l \left\{ \tan \left( \frac{45^\circ}{2} + \frac{1}{2} \theta \right) \right\}.$$  Here no correction is wanted, because \(v = 0\), then \(z = l \left( \tan \left( 45^\circ \right) \right) = l \cdot (1) = 0,\) as it should be.

If we compare the fluxion of $z$ with that of the difference of a parabolic arc and its tangent, (art. 158), it will appear that they are identical. Hence we have this elegant theorem. If, from the focus of a parabola, a perpendicular be drawn to any tangent to the curve, and a circle be described on the focus as a centre to pass through the vertex; the meridional parts corresponding to the arc of the circle between the vertex, and the perpendicular to the tangent, is equal to the excess of the parabolic arc between the vertex and point of contact, above that portion of the tangent which is intercepted between the same point and perpendicular.

Henry Bond, in the year 1650, discovered, by chance, that the enlarged meridian might be expressed by the logarithmic tangents of half the complements of the latitudes, a rule easily found from the preceding solution; but the difficulty of proving this was then considered so great, that Mercator offered to wager a sum of money against any person that should undertake to prove it, either true or false. James Gregory, however, proved it in his Exercitaciones Geometricae, published in 1668, and afterwards Barrow, in his Geometrical Lectures; their demonstrations, however, were intricate. Afterwards Dr. Wallis and Dr. Halley gave demonstrations, which were sufficiently simple and elegant.

Quo ad 2. A body $T$ proceeds uniformly along a straight line $BC$, (Fig. 43), and a body $S$ in pursuit of $T$, moves always directly towards it, with a velocity which is to that of $T$ in the given ratio of $1$ to $n$; what is the nature of the curve described by $S$?

Let the tangent $AB$, which makes right angles with $BC$, be put = $a$, the absissa $BR = x$, the ordinate $RS = y$, the arc $AS = z$, then the subtangent $RT = -y \frac{dx}{dy}$ (art. 67) and $BT = x - y \frac{dx}{dy}$; Now $BT$ and $AS$ being described in the same time, they are to each other as the velocities $n$ and $1$, therefore $BT = n \times AS$, that is $x - y \frac{dx}{dy} = n z$, and hence, taking the fluxions, making $dy$ constant, $-y \frac{dx}{dy} = n dz$; but $dz = \sqrt{(dx^2 + dy^2)}$, therefore

$$n \frac{dy}{y} = \sqrt{\left( dx^2 + dy^2 \right)},$$

Put $dx = p \, dy$, then $dx \cdot dy = p \, dy$, and hence, by substitution in the second member,

$$n \frac{dy}{y} = \sqrt{(1 + p^2)}$$

and taking the fluents,

$$c = n l \left( \frac{y}{p} + \sqrt{(1 + p^2)} \right). \]"
Now, because \( p = \frac{dx}{dy} = \tan \), RST (art. 67) when
\( y = a \), then \( p = 0 \); in this case the general equation of the
flucts becomes \( c - n \cdot l(a) = 0 \); therefore \( c = n \cdot l(e) \),
hence \( n \cdot l(a) = n \cdot l(e) \cdot y = 1 \cdot \left\{ \frac{p + \sqrt{(1 + p^2)}}{1 + p^2} \right\} \), and
\( \frac{dy}{dx} = 1 \cdot \left\{ \frac{p + \sqrt{(1 + p^2)}}{1 + p^2} \right\} \), and \( \frac{dx}{dy} = p + \sqrt{(1 + p^2)} \).
By resolving this equation in respect of \( p \), and putting
for \( p \) its value \( \frac{dx}{dy} \), we find
\[ 2 \cdot dx = \frac{a^2 \cdot dy}{y^a} - \frac{y^a \cdot dx}{y^a} + \frac{2 \cdot na}{1 - n^2} \]
and the taking the fluncts a second time,
\[ 2 \cdot x = - \frac{a^2 \cdot y^{1-a}}{1 - n^2} - \frac{a^2 \cdot y^{1+a}}{n^2} + \frac{2 \cdot na}{1 - n^2} \]
This line is the curve of pursuit remarked by Bouguer and Maupertuis, (Mem. de l'Acad. des Sciences, 1732).

**Problem 3.** If any number of straight lines are drawn according to some determinate law, it is required to find the nature of a curve to which these are tangents.

For example, let \( AE \) be a straight line given by position, (Fig. 45), and \( K \) a given point without it; let any number of lines \( KD \), \( KD' \), &c. be drawn, to meet \( AE \) in \( D \), \( D' \), &c.; and let \( AB \), \( BC \), \( DC \), \&c. be drawn to these lines; it is required to find the nature of the curve \( ACC' \), to which these perpendiculars are tangents.

Without attending to the particular case, we shall resolve the general problem, and suppose \( AE \) to be the axis of the curve (Fig. 44). A being the origin of the co-ordinates, and \( CD \) any position of the tangent, which meets the axis in \( D \). From the point of contact \( C \), draw the perpendicular CB; and, considering \( C \) as a point in the curve, put \( AB = x \), \( BC = y \); but again considering \( C \) as any point whatever in the tangent, put \( AB = x' \), \( BC = y' \). Then, whatever be the conditions that determine the position of the tangent, the relation of \( x' \) and \( y' \) the co-ordinates of any point in it, may be expressed by the equation \( y' = P \cdot x' + Q \), where \( P \) and \( Q \) are put to denote generally certain functions of constant quantities, and some quantity \( p \), which has the same value for any given position of the tangent, but which changes its value if the tangent changes its position. For example, \( p \) may express the angle which the tangent makes with the axis, or it may represent the sub-tangent BD, &c.

Let us now suppose that the variable quantity \( p \) changes its value and becomes \( p + h \), and that \( C' \) is the new position of the tangent corresponding to \( p + h \); then, considering \( p \) and \( Q \) as functions of \( p \), by Taylor's theorem (art. 52.)
\[ P \text{ becomes } P + \frac{dP}{dp} h + \frac{d^2P}{dp^2} \frac{h^2}{2} + &c. \]
\[ Q \text{ becomes } Q + \frac{dQ}{dp} h + \frac{d^2Q}{dp^2} \frac{h^2}{2} + &c. \]
The relation of \( x' \) to \( y' \) in the new position of the tangent will now be expressed by the equation
\[ y' = P \cdot x' + Q + \left( \frac{dP}{dp} \cdot x' + \frac{dQ}{dp} \cdot h \right)^2 + K \cdot h^2 \]
Where \( K \cdot h^2 \) &c. is put for all the remaining terms of the series.

Now, as this equation holds true of every point in the tangent \( C'D' \), and the equation \( y' = P \cdot x' + Q \) holds true of every point in the tangent CD, it follows, that at \( e \), the intersection of the two tangents, both equations must be true at the same time; therefore at \( e \) we have
\[ \left( \frac{dP}{dp} \cdot x' + \frac{dQ}{dp} \cdot h \right) + K \cdot h^2 + &c. = 0; \]
and dividing by \( h \), \[ \frac{dP}{dp} \cdot x' + \frac{dQ}{dp} \cdot h + K \cdot h + &c. = 0. \]
Conceive now the two tangents to approach to coincidence; when \( C' \) come to \( C \), then \( e \) will also fall at \( C \); and \( h \), and \( e \), all the terms into which it enters, vanish; also \( x' \) and \( y' \) become \( x \) and \( y \), and to determine the nature of the curve, we have these two equations:
\[ y = P \cdot x + Q \]
\[ 0 = \frac{dP}{dp} \cdot x + \frac{dQ}{dp} \]
By eliminating \( p \) from these, the resulting equation will express the nature of the curve.

**Example 1.** Let us now recur to the particular case of \( AE \), a straight line given by position (Fig. 45.), \( K \) a given point, and \( KDC \) a right angle: Draw \( KA \) perpendicular to \( AE \); put \( AB = x \), \( BC = y \), \( KA = a \), and let \( AD \) be the variable quantity \( p \). The triangles \( KAD \), \( DB \) are similarly; therefore \( KA = \frac{AD}{BD} = \frac{DB}{BC} \); that is, \( a = \frac{p}{x - y} = \frac{y}{x} \); hence \( ay = px - p^2 \), and
\[ y = \frac{p}{a} x - \frac{p^2}{a} \]
Compare this with equation (1.), and it will appear that \( P = \frac{p}{a} \); \( Q = - \frac{2p}{a} \); therefore \( \frac{dP}{dp} \]
\[ \frac{dQ}{dp} \]
The second of these equations gives \( p = \frac{a}{2} x \); and hence the first becomes \( y = \frac{p^2}{2a} \); therefore \( 4 \: a \: y = x^2 \); is the equation of the curve, which is evidently a parabola, of which \( AK \) is the axis, \( K \) the focus, and \( A \) the vertex.

**Example 2.** Suppose a ray of light \( RD \) (Fig. 36.) coming \( FEG \), from the sun to fall upon \( FEG \), the concave surface of a sphere at \( D \); and to be thence reflected in the direction \( DI \); it is proposed to find the nature of the curve to which this, and all rays reflected in the same manner, are tangents.

Draw \( AD \) the radius of the sphere, and \( AB \) parallel to the incident ray \( RD \); let \( C \) be the point in which the reflected ray touches the curve; let \( DC \) meet \( AE \) in \( H \), and draw \( CB \) perpendicular to \( AE \). Put \( AD = a \), \( AB = x \), \( BC = y \), and let \( p \) be the variable angle \( DAE \).

By the principles of optics, \( AD \) bisects the angle \( RDI \), which is equal to \( DHE \), that is to the sum of the angles \( DAD \), \( ADH \); therefore the angles \( DAD \), \( DAH \), \( DAI \) are equal; and angle \( DHE = 2p \). Now, by trigonometry,
FLOXIONS.

For we curve $f(x, y, p) = 0$,

and this expression, by Taylor's theorem, is equivalent to

$$f(x', y', p + h) = 0.$$ 

The fluxion being taken upon the hypothesis that $p$ alone is variable, and $K h^2$ &c. being put for all terms of the series following the second, each of which is multiplied by a power of $h$.

Let the two curves intersect each other in $c$, and let $A b = x$, and $b c = y$, be the common co-ordinates; then, as equation (1) holds true of every point in the curve $H C D$, and equation (2) holds true of every point in $H'C'D'$, both must hold true at once, if we substitute in them $x$ and $y$, the co-ordinates belonging to their common point $c$; that is, we must have

$$f(x, y, p) = 0,$$

and hence we must also have

$$d \left\{ f(x, y, p) \right\}_x + K h^2 + &c. = 0,$$

Let $C$ and $C'$ be now supposed the points in which the curves $H e D$, $H' e D'$ touch the curve $P C C' Q$, whose nature is required; then, if we suppose $h$ to decrease continually, and at last to vanish, the points $C'$ and $c$ will approach to $C$, and at last will coincide with it, so that $x$ and $y$, which are co-ordinates of $c$, the intersection of the two curves $H e D$, $H' e D'$, will then become the co-ordinates of the curve $P C Q$. As all the terms which contain $h$ will then vanish, we have evidently this rule.

Let the equation of the given curves be

$$f(x, y, p) = 0,$$ 

$x$ and $y$ being the co-ordinates, and $p$ a variable parameter. From this equation, by taking the fluxion, supposing $p$ to be variable, and all the other quantities constant, deduce this other equation,

$$d \left\{ f(x, y, p) \right\}_x = 0.$$ 

By these eliminate $p$, and the result will be an equation, which expresses the nature of the curve, that touches all the given curves.

This formula includes in it that of Prob. 3.

Example. Let $A C D$, $A C D'$, &c. be parabolas described by a projectile thrown from a given point $A$, with a given velocity in a given vertical plane. It is proposed to find the curve $F C Q$ which touches them all. Let $E F$ be the axis of any one of the curves, $A D$ an ordinate to the axis, $A P = a$, the height due to the velocity of projection (see projectiles), $A B = x$, $B C = y$, the co-ordinates of $C$, any point in the curve. Put the parameter of the axis $= p$, and considering $A D$ as a function of $p$, which is to be regarded as variable, put $A D = q$. 

\[ \text{Miscellaneous Problems.} \]

\[ \text{Miscellaneous Problems.} \]
By the theory of projectiles, \( EF = a - \frac{1}{2} p \), and by
the nature of the parabola, \( AF^2 = pg \times EF \), and \( AB \times BD = p \times BC \); hence we have these two equations,
\[
q x - x^2 = p y, \quad (1)
q' = 4 a p - p^2, \quad (2)
\]
From the first of these,
\[
f(x, y, p) = x^2 + p y - q x = 0,
\]
and taking the fluxions, considering \( x \) and \( y \) as constant,
and \( q \) as a function of the variable quantity \( p \),
\[
df(x, y, p) \over dp = y - \frac{dq}{dp} x = 0,
\]
therefore \( y = \frac{dq}{dp} p \); but from equation \( (2) \), taking the
fluxions, \( q d q = 2 a d p - p d p \), and hence \( \frac{dq}{dp} = \frac{2a - p}{p} \),
and by the first equation \( \frac{y}{x} = \frac{q}{p} \), therefore \( \frac{q}{p} = \frac{2a - p}{p} \), and hence \( q^2 - q x = 2 a p - p^2 \), and substi-
tuting for \( q^2 \) its value given by equation \( (2) \), we get
\[
q x = 2 a p \quad \text{and, hence, by equation \( (1) \)},
\]
\[
P = \frac{x^2}{2a - y} \quad q = \frac{2a x}{2a - y}.
\]
These values of \( p \) and \( q \) being substituted in the second equation,
and the common denominator rejected, it becomes
\[
4 a^2 x^2 = (8 a^2 - 4 a y - x^2) x^2.
\]
Hence, \( 4 a y = 4 a^2 - x^2 \), and this is the equation of
the curve \( FCQ \), which is evidently a parabola, having
its focus at \( A \), the common intersection of all the parabolas,
its axis perpendicular to the horizon, and its parameter \( = 4 a \).

The geometrical theory comprehended in the third
and fourth problems, has a corresponding analytical
theory relating to the fluents of certain fluxional equa-
tions. This is the theory of singular primitive
equations, which are not included in the complete
primitive equation. Thus, the fluxional equation
\[
dy \sqrt{(x^2 + y^2 - b)} - y d x + x d x = 0,
\]
has for its complete primitive equation
\[
x^2 + y^2 - b = 0,
\]
where \( a \) is the arbitrary constant quantity; but besides
this, it has a singular primitive equation
\[
x^2 + y^2 - b = 0,
\]
which does not admit of an arbitrary constant corre-
cction, although it equally satisfies the fluxional equation,
as is easily proved by taking the fluents. The bounds
within which it was proper to confine this treatise, have
not allowed us to enter into this branch of the subject,
which, although interesting, is yet not elementary. On
this subject, see Euler, *Intitut. Cal. Integ.* vol. i. sect. 3.
cap. 4; *; Lagrange, Mem. de l'Acad. Ber. 1774; also,

place, Mem. de l'Acad. Par. 1772; Legendre, Mem.
Acad. 1790; Poisson, Journal de l'Ec"ole Polytechnique
15 Cahier.

Prob. 5. Supposing the two poles of a magnet to be
given by position, and that the force of each is recip-
rocally as the nth power of the distance from it; it is
required to find a curve in any point of which a needle
(indifinitely slight) being placed, its direction, when at
rest, shall be a tangent to the curve.

To resolve this problem, it must be known that the
north pole of the needle is repelled by the north
pole of the magnet, and attracted by its south pole;
and that the south pole of the needle is repelled by
the south pole of the magnet, and attracted by its north
pole. Let \( N \) (Fig. 48) be the north, and \( S \) the south pole
of the magnet; and let \( NCS \) be the curve; and \( AB \) a
straight line in the direction of the needle, which be-
ing, by hypothesis, indefinitely short, its poles may be
considered as coinciding with its centre \( C \); Join \( CN \),
\( CS \). By the laws of magnetism, the attractive and
repulsive forces of \( N \) and \( S \) are equal at equal distances.
Therefore, if we take \( Cg \) and \( Cf \) proportional to the
attractive force of \( N \) on the south pole of the needle,
or its repulsive force on the north pole; also \( eg \) and
and \( e \) proportional to the attractive force of \( S \) on the
north pole, or its repulsive force on the south pole of
the needle, and complete the parallelograms \( e \) \( A \) \( C \) \( s \),
\( fCg \) \( n \), which will be equal in all respects, and have
their diagonals \( Cz \), \( Cn \) in the same straight line, by
the principles of statics, the needle can only be at rest
when its direction \( AB \) coincides with the diagonals
\( S \) \( C \) \( n \); because then, the forces \( Cz \), \( Cn \), which act
upon its poles, pass through its centre.

Put \( NC = p \), \( SC = q \); by hypothesis \( p^2 : q^2 = Cg : Cf \)
or \( Cg : Cf \) or \( Cg \), but \( Cg : Cg \) or \( Cg \) or \( Cg \) \( g \) \( n \) : \( \sin \ Cng : \sin \ Cg \),
that is as \( \sin \ ACN : \sin \ BCS \), therefore
\[
p^2 : q^2 = \sin \ ACN : \sin \ BCS.
\]
From this geometrical property of a tangent to the
curve, we are now to find an equation by which any
number of points in it may be determined.

Let the angles \( CNS = \Phi \), and \( CSN = \Psi \), and put \( z \) for
the arc of the curve \( NC \). It appears by art. 69, (for-
formula 6,) that the tangent of the angle \( ACN \) is equal to
\[
-\frac{p d \Phi}{d p},
\]
therefore its secant will be \( \sqrt{(p^2 d \Phi^2 + d p^2)}
\]
and the numerator of this fraction expresses the fluxion
of \( z \) (art. 76, formula 2), therefore, \( \sec \ ACN = \frac{d z}{d p} \)
and as \( \sin \ ACN = \tan \ ACN \), therefore, \( \sin \ ACN =
\[
-\frac{p d \Phi}{d z}.
\]
Similarly, we have \( \sin \ BCS = \frac{q d \Psi}{d z} \), (here the
sign is positive, because the arc and angle increase to-
gether;) we have therefore \( p^2 : q^2 = \frac{d \Phi}{d z} : \frac{d \Psi}{d z} \)
and \( p^2 = 1 : q^2 = 1 : -d \Phi : d \Psi \); but in the triangle \( NCS \),
by trigonometry, \( p q = \sin \Phi : \sin \Psi \); therefore \( \sin^{-1} \Phi : \sin^{-1} \Psi \),
\( -d \Phi : d \Psi \), hence we get \( \sin^{-1} \Phi d \Psi = -\sin^{-1} \Psi d \Phi \), and
\[
\int \sin^{-1} \Phi d \Phi + \int \sin^{-1} \Psi d \Psi = c,
\]
an equation which expresses the nature of the curve.

If the force be supposed inversely as the distance,
then \( n = 1 \), and the equation is \( \Phi + \Psi = c \), a constant
angle; hence it appears, that in this case, the curve is
an arc of a circle passing through \( N \) and \( S \).

If the force be inversely as the square of the distance,
then \( n = 2 \), and the equation of the curve is
\[
\int \sin \Phi d \Phi + \int \sin \Psi d \Psi = c,
\]
or taking the fluents,
\[
\cos \Phi + \cos \Psi = c.
\]
If a semicircle be described on \( DS \) as a diameter,
cutting \( CN \), \( CS \) in \( H \) and \( K \), it is easy to see that \( NH \),
\( SK \) are to each other as the cosines of the angles \( S \), \( N \);therefore, by the nature of the curve, \( NH + SK \) will be
constant. By this property, if, besides the points \( N \), \( S \), any other point \( C \) be given, we can
find as many more points in the curve as we please.
FLUXIONS.

From experiments, it appears, that the supposition of \( n = 2 \) agrees pretty well with the common phenomena of magnetism.

If \( n \) be supposed to have any other integer value, the fluents may be found by article 144.

Prop. 6. Suppose that a material point, placed at \( A \), is impelled by two forces, one which urges it from \( A \) towards \( B \), (Fig. 49.) with a motion uniformly accelerated, and the other on the contrary urges it from \( A \) towards \( D \), with an intensity which is in the inverse ratio of the distance of the material point from \( B \); it is proposed to determine the principal circumstances of the motion.

Let \( AB = a \), \( AN = s \), the space described by the point in a variable time \( t \), and \( v \) the velocity which it acquires in the same time; let \( f \) denote the accelerating force, which impels it from \( N \) towards \( D \), and \( m \) the value of the force at some given distance, (an unit,) from the point \( B \): By the nature of the question

\[
\frac{1}{a^2 + s^2} - \frac{1}{f^2} = \frac{m}{f^2} - \frac{m}{a^2 + s^2},
\]

Again, let \( g \) denote the constant accelerating force which acts upon the moveable point from \( N \) towards \( B \); the force \( F \), which actually impels it at the end of the time \( t \), is the difference of these two forces, therefore \( F = f - g \).

From this expression, and the principles of Dynamics, (which see), we have these three equations

\[
F = \frac{m}{a^2 + s^2} - g, \quad F = \frac{m}{a^2 + s^2} - g, \quad F = \frac{m}{a^2 + s^2} - g.
\]

By these we may eliminate any two of the four quantities \( F, s, v, t \).

From the first and second we get \( v \delta v = \left( \frac{m}{a^2 + s^2} - g \right) ds \);

and hence, taking the fluents

\[
\frac{1}{2} v^2 = m \log \left( \frac{a^2 + s^2}{a^2 + s^2} - g \right) + c;
\]

To determine \( c \), it is to be observed that at \( A \), we have \( v = 0 \), and \( s = 0 \), hence \( c = -m \log a \), and the adjusted equation of the fluents is

\[
v = \pm \sqrt{2 m \times \log \left( \frac{s^2 + a^2}{a^2} - 2g \right)}.
\]

This equation gives the velocity which the moveable point has acquired after it has described the space \( s \). To determine the time \( t \), we must substitute for \( v \) its value in the equation \( \frac{ds}{dt} = \frac{v}{m} \), and then take the fluent, which however must be found by approximation or infinite series.

If we suppose \( DB \) to be a cylindrical tube, open only at the upper end \( D \), and \( A \) to be a piston, which fits the tube exactly, and descends vertically by the force of gravity, compressing the air in \( AB \) the lower part, then, as the force of the compressed air to urge the piston upwards, is known to be inversely as the space it occupies, that is inversely as \( AB \), and as at the same time the piston is urged downwards by the force of gravity; if we abstract from friction, the piston will be urged by two forces exactly as we have supposed the material point in the enunciation of the general problem.

We have another example of this kind of motion in a bullet fired from a musket or cannon: By the ignition of the gunpowder, the space it filled is suddenly occupied by a great quantity of elastic vapour, which in expanding, forces the bullet along the tube.

If we suppose \( x = AD \), the distance from the mouth of the cannon at the beginning of the motion of the ball; \( a + s \) is the whole length of the cannon, then \( v \) will be the velocity with which the ball leaves it: We may abstract from the resistance of the air and the weight of the bullet, which alter this velocity very little, beside when the cannon is horizontal, the weight is nothing: Therefore, making \( g = 0 \), we have

\[
v = \sqrt{2 m \log \left( \frac{s^2 + a^2}{a^2} \right)}
\]
a formula which is applicable to Gunnery.

For other examples of the application of fluents to the theory of forces, see Dynamics, Sect. 5. (4)

FLYING, Artificial. Mankind have always viewed the flight of the feathered tribes as an enviable facility; they have ascribed it to beings more favoured than themselves, whose power was courted or dreaded by them; and, after indulging in innumerable fictions and legends concerning its operation, in regard to terrestrial objects, they have entertained expectations that it is one of the prerogatives of a celestial state. Some more hardly and intelligent, however, have even, from the remotest ages, conceived the practicability of conveying themselves through the air by mechanical expedients. But so incompatible has it appeared with the physical structure and abilities of the human frame that "to fly in the air" has universally been regarded as one of those chimerical projects which no ingenuity could realize. Hence the learned Bishop Wilkins has truly observed, "amongst other impediments of any strange invention or attempts, it is none of the meanest discouragements that they are so generally derided by common opinion, being esteemed only as the dreams of a melancholy distempered fancy." Yet, on considering the nature of the atmosphere in common with other fluids, the disposal of matter of known specific gravity, and the application and effect of the mechanical powers, it does not seem altogether logical to declare it impossible for mankind to elevate themselves in the air by means of wings.

Though more peculiarly the attribute of birds and insects, flight is not denied to quadrupeds. A species of squirrel is provided with two broad membranes, connecting the fore and hind limbs, by means of which it accomplishes leaps resembling short flights. The numerous bats which inhabit every region, enjoy the privilege in the highest extent. We know also that there is a fish which can leave the sea, and support itself for a short time in the air, by the size and action of its fins, forming a substitute for wings. It is chiefly, however, in birds and insects that we find the full exercise of this admirable faculty, which is attained by organs very different in appearance and structure. Indeed, on attending to those of Insects, nothing can be more diversified, or, in certain species, more remote from the wings of birds. The bodies of some scarcely bear any proportion to their enormous wings, as in several genera of butterflies; while the wings of grasshoppers, bees, and many species of diptera or two-winged insects, and beetles, seem incapable of supporting the body. The wings of birds are invariably form-
ed of feathers, long and light, and in general tapering to a point; those of insects consist, in some, of a thin membranous substance, covered with scales, which fall off in a powder, or of a reticulated frame, or of thick horny plates conjoined with the thinnest membranes. But all these varieties perform analogous functions, in enabling the animals to accomplish their aerial navigations. Nevertheless, their mode of action is not alike, and great specific gravity is overcome by the rapidity of percussion on the air. Thus, the broad wings of the butterfly, slightly erected, sustain it as if floating above, while the wings of the humming bee are in the quickest motion during its flight. There is also a considerable variety in the structure of birds, and in their powers of flying. Some, as the kite, the eagle, and the swallow, rise to an incredible height, while the pigeon, the ostrich, and the emu, are incapable of elevating themselves from the earth. The pigeon is provided only with short feathered stumps; the ostrich has wings which are never employed, but to assist it in running; and the texture of the whole plumage of the emu plainly evinces, that it is not formed for flight. It is not a covering of feathers, therefore, that imparts the faculty of aerial transportation; nor is it essential that wings should be composed of light substances.

Mankind have considered it possible to attain this faculty by the aid of artificial wings; and have always resorted to them, in history and fiction, as the primary mode of rising aloft in the air. It is an idea that has been equally indulged by the ancients and the moderns. Daedalus thought to effect his escape from Crete, by the close imitation of nature, as pictured by Ovid.

*Metamorph. Lib. 8.*

But the ancients went farther than the mere conception of such efforts; for we are told that they constructed machines in the figure of animals, which could actually fly. At the same time it must be acknowledged, that this is rather reported from tradition, than described by spectators, as the wooden pigeon of Archytas, which is alluded to by Aulus Gellius, in these words, "Sei il quod Archytam Pythagorum commentum esse atque fecisse traditur: neque minus admirabile neque tomen varium atque sideri debet, nam et plerisque nobilibus Graecorum et Graecorum philosophus memoriarum veterum exsequiuntissimus afferrebat hic scripturum, similem columbam et igno ab Archytone quado. discipulique mecanica factum volans; ita erat scilicet librarum is suspensum et aura spiritus inclusa atque occulto coitum." Thus the account is less singular than could be desired of so singular a contrivance; and, although it has been imitated by the moderns, there is the same defective explanation. After Charles V. resigned the crown, various expedients were invented to amuse his leisure hours; among these was the mechanical flight of artificial sparrows, which being allowed to escape from his apartment, performed various evolutions in the air. Before his demission, indeed, it is said that an ingenious mechanic constructed an eagle, which flew from Nuremberg to meet him, on his approach to that city; and the same mechanic is reported to have constructed an iron fly, which having left his hand, flew about, and at length, as if weary, returned to its master. Later mechanisms have been content with representing the motions of birds on the earth, but not in flight; though this is perhaps less difficult than may be supposed.

Bishop Wilkins considers, "that there are four several ways whereby this flying in the air hath been or may be attempted, two of them by the strength of other things, and two of them by our own strength, 1. by spirits or angels; 2. by the help of fowls; 3. By wings fastened immediately to the body; 4. By a flying chariot." The first he rejects as not being founded on natural and artificial grounds, and the last we have seen realised in the modern invention of balloons; the second has hardly ever been tried, though the extreme docility of animals might apparently be an encouragement; but the third has excited repeated notice, and the ingenious have endeavoured to reduce it to practice.

The chief and principal obstacle has been found in that law of nature, whereby bodies of greater specific gravity than the fluids wherein they are immersed sink in them; but this proposition is liable to modification, partly resulting from the figure of the body and the motion of the fluid. Rural observers cannot fail to have remarked, that towards autumn the dandelion, a common plant, is covered with a downy substance, continually wafted away by the wind. In a calm it falls to the ground, but in a gentle breeze, it rises high, and advances with steady progression in the air, until it escapes from our sight. On more minute inspection, this substance is discovered to represent a parachute in miniature; the head is feathery, and at the end of the stalk is a seed attached, of far greater specific gravity than the atmosphere. The real down also, which we see floating around us, is of considerable specific gravity; and it is singular that it is not those birds most amply provided with it, nor those of the least specific gravity, that fly the greatest distances. If the feathery substance could be put in motion while the air is at rest, or if an analogous machine, very light, could strike the surrounding atmosphere by any means that could be devised, its rise and progressive motion would be certain.

We read of attempts at artificial flying in various countries and at different intervals, but we are left without information respecting the means employed: it has been conjectured, however, that most of these performances resembled the descent of mountebanks on ropes, from lofty places, secured by a ring or traveller, while the agitation of wings attached to their shoulders broke the force of the fall. Such was the exploit of an Arragonese who, at the coronation of Edward VI. descended a rope compared to a ship's cable stretched from the battlements of St Paul's steeple to the ground, "running on his breast as if it had been an arrow out of a bow." Of the like description were the exhibitions of a juggler on a rope stretched from the top of St Giles's steeple in Edinburgh, and fastened below the cross in 1598. But these feats of address had frequently a fatal termination; as that of another performer from the battlements of St Paul's in the reign of Mary; and as happened at Shrewsbury in the year 1739, where one, who was no mountebank, having successfully performed several tricks on a rope extended from the top of St Mary's steeple, attempted to descend it across the river, when it broke, and he was dashed to pieces by the fall. In the strange pageantry of old, exhibited in these kingdoms and elsewhere, there are repeated allusions to angels, or divinities provided with wings, flying to meet sovereign princes on their triumphal entry into cities; but the mode in which this was accomplished is not described.
FLYING.

During the darker ages, when the possibility of aerial transportation was ascribed to necromancers, Roger Bacon, a man of the most comprehensive genius, speaks of attaining it by wings attached to a machine. In his singular work De Mirabilibus Potestatum Artis et Naturae, he uses the following expressions. *Possunt fieri instrumenta volandia, ut homo sedens in medietate instrumenti volovellas aliquod ingenium, per quod alia artificialia compositae aeream verberent ad medium aevum volantis.* That is, it is possible to make a flying machine, so that a man sitting in the middle, can, by some expedient, produce a rotary motion, which shall occasion the percussion of artificial wings on the air like the flight of a bird; and in another passage, he observes, "that a flying machine has undoubtedly been made in our own time, not that I saw it, nor did I know any one who had done so, but I am acquainted with an intelligent person who has conceived such a contrivance." Though the passage is not void of obscurity, by combining it with the former, the author's meaning may be gained. Bacon lived in the thirteenth century. Not far from the same period, and in the succeeding centuries, we are told of a certain monk, Eremerus, who flew above a furlong from the top of a tower in Spain. Another flight was attempted from St. Mark's steeple in Venice, and also at Nuremberg: and by means of a pair of wings, a person named Dante of Perouse, was enabled to fly; but while amusing the city with his flight, he fell on the top of St. Mary's church and broke his thigh. The subject of aerial navigation received still greater attention in the seventeenth century, as the works of Lema, Hook, and Wilkins testify; and contemporary with them, one Besnier, a locksmith of Sable in France, obtained considerable effect from the aid of four wings. In the only imperfect description of them preserved, they seem to have been four rectangular surfaces, one at the end of each of two rods passing over the shoulders of him who used them, and the posterior two connected by a cord to his ankles. The inventor did not pretend that he could rise from the earth or sustain himself long in the air, from inability to give his apparatus the requisite power and rapidity; but he progressively availed himself of its aid to leap from a window one storey high, next from the second storey, and then from a roof, whereby he was enabled to visit the neighboring houses. By leaving an elevated position, he could cross a river of considerable breadth, or any similar obstacle. His first pair of wings were purchased by M. Baladin of Guibre, who used them with success. This was recently preceding the year 1678; and in the beginning of the next century, Bartholomew Laurence de Guzman, a Portuguese, contrived some strange machine, partly formed with wings like a bird, of which scarcely any intelligible account has been transmitted to us. But while one set of mechanics and philosophers encouraged each other with the hopes of aerial navigation, Borelli, a Neapolitan mathematician, declared that it was impossible for men to fly by their own strength, *inur non postre ut homines propriae virtutis auree possint;* and perhaps this has been one cause of more attentive investigation into the properties enabling birds to fly, or the methods which might be adopted by men.

As it is neither those which are of the smallest specific gravity, or clothed with the lightest down, that are most capable of flight, it follows that flying is accomplished merely by a mechanical operation; more particularly on considering how much it is diversified among the feathered tribes; one bird is continually soaring aloft at the greatest altitudes, another skims the earth without intermission, while a third only displays its wings occasionally, and is as if propelled by another agent when they open or close. Bishop Wilkins, that ingenious philosopher, whose works are too little studied at the present day, judiciously observes: "We see a great difference betwixt the several quantities of such bodies as are commonly upheld by the air; not only little gnats and flies, but also the eagle and fowls of vaster magnitude." Many insects, even some in this country, exceed the diminutive size of the humming bird, which is but an eighth of an ounce in weight. It is almost constantly on the wing, apparently sipping with its tender bill from the nectarium of the flowers. An enormous bird, the condor of South America, is calculated to be 8162 times heavier: "What an amazing disproportion of weight!" exclaims a modern author; "yet, by the same mechanical use of its wings, the condor can overcome the specific gravity of its body with as much ease as the little humming bird. But this is not all; we are informed that this immense bird possesses a power in its wings so far exceeding what is necessary for its own conveyance through the air, that it can take up and fly away with a whole ship in its talons, which should, in case as an eagle were to carry off, in the same manner, a hare or a rabbit. This we may readily give credit to, from the known fact of our little kestrel, and the sparrow hawk, flying off with a partridge, which is nearly three times the weight of either of these rapacious little birds." A calculation is next made of the combined weight of the condor and its prey, which amounts to 20,405 times the weight of the humming bird, to be borne through the air. Probably the author would have found similar illustrations among the more rapacious winged insects, whose wings are less adapted for it. But he proceeds with another comparison, to prove that the length of the wings of birds is not augmented in proportion to the increased weight of their bodies, whence he infers the possibility of constructing a machine with which a man should be enabled to fly. "The condor carries ten stone with wings of 12 feet expansion from tip to tip. The humming bird carries one drachm with three inches expansion; the common wren is three times as heavy as the humming bird, and has but one inch more of wing: a pigeon weighs 16 ounces, which is 256 times as heavy as it is, and has only ten times more expansion of wing: the goat-sucker is 40 times as heavy, and has seven times the length of wing. Therefore, as a man weighing ten stone, and a machine to bear him two, will only exceed the weight of the condor and its prey by one fifth part, and as the wings of the condor are about 12 feet; suppose we make a pair of wings of silk, one fifth longer than they are, which will be about fourteen and a half. I am thoroughly persuaded they will be found amply sufficient, as they will far exceed the progressive increase of birds wings."

Authors have even speculated on the fashion and substance of the wings, and in general have concluded that they should be analogous to those of birds. Bishop Wilkins, after observing that if there be any such artificial contrivances that can fly in the air, then it will clearly follow, that it is possible also for a man to fly himself; and he recommends the wings to be formed of feathers, like those employed by Dredalbus, or else of one uninterrupted substance like those of bats. "But now because the arms extended are but weak and easily weary'd, therefore the motions by them are like to be but short and slow, answerable, it may be, to the flight of such domestic fowl as are most conversant on the ground; and therefore much more would the arm of
FLYING.

a man, as being not naturally designed to such a motion. It were therefore, worth the enquiry, to consider whether this might not be more probably effected by the labour of the feet, which are naturally more strong and indefatigable. In which contrivance the wings should come down from the shoulders on each side; and the motion of them should be from the legs being thrust out and drawn in again, one after another; so that each leg should move both wings, by which means a man should as it were walk or climb up into the air." In all later proposals, however, the idea of flying by exerting the animal powers alone on wings, has been abandoned; though the utmost confidence of its success continues still to be entertained, and, as we shall immediately see, it has actually been put in practice. The close imitation of nature, also, under the modification required by the difference of materials, is invariably to be preserved.

Among the most recent authors on this subject, may be named Sir George Cayley, who endeavours to show that there is nothing adverse to the soundest reasoning in expecting to overcome the difficulties which men experience in elevating themselves in the air. He shows that flight is purely mechanical, for by a simple experiment in disposing four quill-feathers at right angles to each end of a rod, and presenting an oblique surface to the air, this apparatus will of itself rise, when a rotatory motion is produced by the relaxation of a spring, and the rod itself ceasing to receive the action of the spring. Sir George Cayley concludes: "The flight of a strong man by great muscular strength," he observes, "though a curious and interesting circumstance, in as much as it will probably be the first means of ascertaining this power, and supplying the basis whereon to improve it, would be of little use. I feel perfectly confident, however, that this noble art will soon be brought home to man's general convenience; and that we shall be able to transport ourselves and families, and their goods and chattels, more securely by air than by water, and with a velocity of from 20 to 100 miles per hour." Bishop Wilkins, indeed, was long ago so confident of success, that he anticipated the period when a person should as readily call for his wings to make a journey, as he then did for his boots and his horse. Sir George Cayley continues: "To produce this effect, it is only necessary to have a first mover, which will generate more power in a given time, in proportion to its weight, than the animal system of muscles." He seems to infer, that he has made experiments on a considerable scale; but we are not acquainted with their nature or result; and we are precluded from discussing his theories, by the necessity of referring to what seems more decidedly practical.

Just about the same time, Mr Walker of Hull, whose sentiments we have already quoted, directly proposes a machine whereby flying shall be accomplished; and he maintains that he is the first person who has discovered the real theory of the flight of birds. On considering the structure of birds, he maintains, that by means of a pair of wings and a tail duly expanded in a perfectly passive state, and aloft in the air, without any muscular motion, a bird procures a suspending power, which counteracts the specific gravity of its body, and prevents its being precipitated to the ground. But this is perhaps assuming too much; for it is probable, that although we are not sensible of the action of the wings in birds apparently suspended motionless in the air, that we would fall to the earth without it. With respect to the quill-feathers, which are here the prime agents, he observes, that, as they were intended to swim in a fluid so light and subtle as the air, it was necessary they should consist of the lightest materials imaginable; that being intended to strike upon the air with great power and effect, it was requisite that the shafts should possess much strength with elasticity. It was expedient, too, that the quill-feathers should shut and open, to let the upper air pass through the wings, to facilitate their ascent when they are struck upwards. It was also necessary that they should all shut close together, forming each wing into a complete surface or web, when they are by the muscular power of the bird forced down, in order to give a more secure hold upon the air below, and by their means keep the bird up. Now, if we do but examine the quill-feathers, we shall find in the shafts astonishing strength with elasticity, and very little specific gravity indeed. The webs are broader on one side of the shafts than the other, which causes them to open as the wings move up, and to shut as they come down, exactly answering the purposes I have already mentioned." With regard to the operation and effect of the wings and tail in an active state, it appears that flight is attained from the resistance of the air or percussion. "When a bird, by the power of its pectoral and deltoid muscles, puts its wings into action, and strikes them downwards in a perfectly vertical direction upon the air below, that air, being compressed by the stroke, makes a resistance by its elastic power against the under side of the wings, in proportion to the rapidity of the stroke and the down-ward motion of the bird upwards: at the same time, the back edges of the wings being more weak and elastic than the fore edges, they give way to the resisting power of the compressed air which rushes upwards against the same back edges, acting against them with its elastic power, and thereby causes a projectile force which impels the bird forward. And thus we see that by one act of the wings, the bird produces both buoyancy and progress. When the tail is forced upwards, and the wings are in action, the bird ascends; and forced downwards, it consequently descends. But the most important use of the tail is to support the posterior weight of the bird, and to prevent the vacillation of the whole."

Fortified by these principles, Mr Walker proposes an apparatus, whereby, from the action of wings, flying shall be attained; and this is to consist of a case formed of light materials, provided with wings of the requisite dimensions, to be put in action by a man sitting, and as if rowing a boat. The wings are recommended to be each about eight feet long when horizontally expanded; and fastened upon the top edge of the car, with two joints each, so as to admit a vertical motion to the wings, which motion may be effected by a man sitting and working an upright lever in the middle of the car. A tail of seven or eight feet long, and the same breadth at its extremity, must be fixed to the hinder part of the car, and spread out flat to the horizon, in the same manner as we see the tail of birds. Considerable attention must be paid to the structure of the wings and tail, a point that has never escaped speculators on this subject; and Mr Walker proposes that the shafts of each are to consist of six slips of thin whalebone, dressed, and tapering to a point; then wrapped together from end to end in a round form with small twine, and filled with cork along the inside. They are next to be covered with silk very compactly woven, and as impervious to the air as possible. This is to be laid on in separate broad slips, and should open to admit the passage of the air as the wings move up, and close together again as they come down, operating in the same manner as the quill-feathers in the wings of
FLY

birds. But such a peculiarity may be found unnecessary on experiment, because, as the author observes, "we see flying squirrels, bats, butterflies, flying fish, &c. with wings formed of compact membranes, all flying exceedingly well." It is essential that the car be externally covered with silk or very thin leather, which must be united to the base of the wings along each side of the car, to prevent, as much as possible, the air from escaping any where but from the back edges of the wings. Should that be neglected, when the air is compressed by the wings being struck downwards, it will rush upwards through the car, and thereby fail of giving that resistance against the under side of the wings, which is necessary to give buoyancy and progression. The whole is to be considered, "as a large artificial bird, and the man placed in the inside as the vital or moving power." Such is the flying machine by which Mr. Walker expects to accomplish a journey to the ethereal regions. In studying its operation, he particularly directs attention to the propulsion occasioned by the reaction of the air against the under side and back edges of the wings. "When the air is struck by the wings, the effect of its reaction against their under side and back edges is similar to that which is caused by the wind blowing with sufficient force against a mill sail when it rushes off on one side, and impels the sail to move, with this difference only, that the sail, being fastened at one end of an axis, is made to revolve; whilst the bird, being at full liberty in the air, is caused, by the expansive power of the air acting with a resisting force against the back edges of the wings, to glide forward in a right line." We shall abstain from following the author in his details respecting the manner in which the aerial navigator is to commence his flight; how he is to clear the tops of houses, trees, and hills, with safety; and how he is to guide himself through the subtle fluids floating high above the earth: but he is no less confident than Sir George Cayley, of the speed of his journey; and in answer to any objections against the possibility of flying, he hopes it will be granted, that flying will be of great use if by such means we can have our letters, newspapers, &c. conveyed to any part of the kingdom, at the rate of 40 or 50 miles in an hour; or if that numerous class of mercantile agents, riders, henceforth be enabled to glide through the air with great expedition in flying machines: or if a man by such means can take a rope to any mariners in distress along the sea-coast, and thereby be the happy instrument of saving their lives: and if the circumnavigator be able to quit his ship, fly, and explore the interior parts of a new-discovered island, free from the annoyance and hostilities of its rude inhabitants."

The expectations of these authors would certainly not be disappointed, could the flight of man, if it be attainable, approach the speed of the feathered tribes. Birds dart through the air; the eye can scarcely follow them; and the largest can almost instantaneously seek those points and altitudes, where they are lost to human view. Some conjecture has been formed of the rate of this extraordinary velocity. Sir George Cayley computes the flight of the common crow at 344 feet in a second, or above 25 miles an hour. Mr. Cartwright calculated the flight of wild ducks on the coast of Labrador, at 90 miles an hour. Spallanzani, by actual experiment, found that a swallow flew 20 miles in 13 minutes, or at the rate of 92 miles an hour; but he conceives, that the swift or martin can traverse no less than 60 miles in 15 minutes.

It appears, that in the year 1808 or 1809, Mr. Degen, a watchmaker of Vienna, actually realised the views of the numerous projectors who preceded him, regarding the flight of men in the air. We regret that we cannot present a description of his machine in detail; but it seems constructed on philosophical principles, and to operate in a manner analogous to the wings of birds, while the effect partly resembles the closing of a parachute stationary on its descent. A frame is made, principally consisting of rods of some strong but light materials, on which the adventurer stands in an erect posture. A heart-shaped wing, nine feet long, eight broad at the swell, and terminating in a point, proceeds from that part of the frame close to each shoulder; and a fan-shaped tail, apparently connected with both wings, proceeds from behind as far as their swell. Each wing is concave like a parachute, and, by a series of cords from the extremity of the different ribs composing it, can be suddenly contracted, so as to give percussion against the air, and consequently by its resistance produce elevation. It is not sufficiently explained how the working of the machine is effected; but it is to be inferred, that this is done by elevating, depressing, or revolving a crank, connected at each extremity with the series of cords, which display or contract the wings. M. Degen is said to have mounted high in the air by the aid of his machine, and to have exhibited a flight resembling that of a bird, not consisting merely in ascent or descent, but in real aerial navigation.

We are hence entitled to conclude, that the elevation of man in the atmosphere by artificial wings, is not beyond the bounds of possibility. Without indulging in fanciful theories, could it be reduced to practice, it assuredly would not be void of utility. The reason why the invention of balloons has not hitherto been eminently beneficial, arises from the unwieldy size, which is an obstacle almost insuperable to guiding them, and which leaves them at the mercy of the winds. It might be otherwise on the employment of wings, for a narrower proportion could be preserved between an air or a tender, of whatever kind or description, and the total volume of the machine, than between the same implements and an inflated balloon. Birds, however, present some physical peculiarities, which man can never hope to imitate: their muscular powers, their corporeal structure, and above all, their mode of respiration, are of a different nature from what is witnessed among terrestrial animals. Hence it is not unlikely that the highest perfection of artificial flight would only be a distant approach to the admirable prerogative which has been conferred on the feathered tribes. (c)

FOCHABERIS. is the name of a small town in the county of Moray, situated on the right bank of the river Spey, a few miles above its mouth. The town stands on a rising ground above the river, and consists of a square with streets entering it at right angles. The houses are neat and well built, and the church, situated on the southern side of the square, is a handsome building. A very large and elegant bridge, built of freestone, and consisting of four circular arches, was lately thrown over the Spey at this town. The two middle arches have a span of 95 feet, and the other two a span
FOG. See Meteorology.

FOGGIA, a town of Naples, in the province of Capitanata. In consequence of the destruction of the old town by an earthquake in 1782, the present town was built with great regularity and neatness. The houses are well built with white stone, and the streets are good. The granaries, in which the corn is preserved, and built beneath the streets and squares; the sides within being faced with stone, and the orifices closed with earth and stones. On account of the insalubrity of the climate, the town is in a great measure deserted in summer, but in winter it is supposed to contain about 20,000 inhabitants. (f)

FOLKSTONE, the Lapis Populi of the Romans, and the Folcestane of the Saxons, is a seaport town of England in the county of Kent. It is situated on uneven ground near the sea, and consists of three irregular streets, built chiefly on the acclivity of a hill. The houses, many of which are good, are principally built of brick. The church, which stands directly on the cliff above the town, is dedicated to St Mary and St Eanswith. It is built in the form of a cross, with a tower rising from the intersections, supported on very large piers, from which spring pointed arches, with plain mouldings. The market-house has been recently built at the expense of the Earl of Radnor. A Free School was founded here in 1674, for 20 poor children. The Baptists, Quakers, and Methodists, have each a meeting-house in the town. There is also a custom-house at Folkstone, and a battery mounting six heavy guns.

Folkstone enjoys a good coasting trade, and ship-building is carried on here to a considerable extent. The inhabitants are, however, principally employed in fishing. The fish is of a superior kind, and consists of mackerel, herrings, sole, whiting, conger eels, plaice, skate, &c. The harbour was small, and preserved principally by jetties; but it has recently been much improved. Before the town there is good anchorage, with eight or ten fathoms of water. Folkstone is a member of the five ports, and is governed by a mayor, 12 jurats, and 24 common councillors, &c. This town was formerly very large, containing 5 parish-churches; but the greater part of it has been carried off by the sea. About a mile and a half to the north of Folkstone, on the top of a high hill, is an ancient camp, comprising nearly two acres. The small bathing village of Sandgate, is about a mile and a half west of Folkstone. A large martello tower has been erected in the centre of the castle of Sandgate; and at St. John's Cliff, on the hill above Sandgate, an extensive range of barracks has been recently built. In the year 1811, there were in the town of Folkstone,

FON. See Fontainebleau.

FONTAINEBLEAU is a town of France, in the department of the Seine and Marne. It is beautifully situated in the forest of the same name, and consists of a principal street, with several smaller ones. Fontainebleau is chiefly celebrated for its royal palace, which is built at the south end of the town. In its external appearance it is very ugly and irregular, having been erected at different times. It consists indeed of four distinct chateaux, each of which has a garden, and contains no fewer than about 900 apartments, most of which are fitted up in the most splendid style. The apartments in which the Pope was detained by Bonaparte; the small room, in which Bonaparte himself abdicated the throne of France; and the bedroom in which he slept before he set off for Elba, are now shewn with great interest to travellers. The gallery of Francis I. contains 26 busts of eminent men upon marble pillars. Among these, the writer of this article observed Alexander the Great, Demosthenes, Cicero, Gustavus Adolphus, Duke of Marlborough, Washington, Colbert, L'Hospital, and a great number of Bonaparte's sides de camps. A large bust of General Dessaux presided at one end of the room. The chapel is extremely beautiful, the floor being variegated with the finest marble; but it had not received any repairs since the revolution. The theatre is remarkably elegant, being adorned with blue and gold. In the middle of a large piece of water stands the pavilion of Louis XIV. Several pieces of water are seen from the palace, and some fine wooded hills, but there is nothing very remarkable about the grounds. The front of the palace, which is opposite to the town, is inclosed with a lofty iron railing, each rail being in the form of a spear with a gilt top, a form which is adopted at all the palaces of Bonaparte.

The forest of Fontainebleau is almost round, and contains about 25,000 acres. It covers several small hills and plains, and the surface of these hills is covered with large insulated stones, which have the appearance of being thrown there by accident. Many fine trees in the forest are in a state of complete decay. Population of the town 9000. (f)

FONTAINE, JOHN DELA, a celebrated French poet, and one of the most original writers of that nation, was born at Chateau-Thierry, in the year 1621. He received a liberal education, but discovered no peculiar talent for poetry until his twenty-second year; at which period his talent power was said to have been kindled by the perusal of some of the odes of Malesherbes. His first essays he was in the habit of submitting to the judgment of a relation of his own, who encouraged him to proceed, and frequently used to read with him Quintilian, Horace, and the best Roman authors. La Fontaine also endeavoured to improve his genius, by an acquaintance with the French and Italian writers; and, from the works of the most eminent Greek authors, he drew many of those fine moral and political maxims, which he has interspersed among his fables.

A desire of enjoying the conversation of men of letters induced him to remove to Paris, where the intendant, Fouquet, soon procured him a pension. He was afterwards appointed gentleman to the Queen Henrietta of England; but the early death of that unfortunate princess put an end to all his hopes of court preferment.
Some time after that event, the generous and witty Madame de la Sablière invited him to reside in her house, offering to provide him with an apartment and all necessaries. The invitation was accepted; and he soon became so domesticated in his new residence, that the lady, having once in a pet turned away all her servants, observed, that she had kept only her three animals,—her dog, her cat, and La Fontaine.

La Fontaine does not appear to have possessed any share of that lively sensibility, which has generally been considered as characteristic of the poetical tribe; on the contrary, he seems to have been gifted with a very extraordinary degree of apathy and indifference. In his conduct and behaviour, he was plain, artless, easy, open, and credulous; he displayed no envy or ambition; he never took umbrage at any thing that was said or done; and he lived long in habits of the most cordial intimacy with the most celebrated wits of Paris. He made no figure in company, but frequently exposed himself to ridicule, in consequence of his awkwardness and absence of mind.

Upon the death of Madame de la Sablière, with whom he had lived upwards of twenty years, he is said to have received very flattering invitations from several of the English nobility; but he was induced to decline them, in consequence of the liberality of the Duke of Burgundy, and the emulation excited among his own countrymen by the generous invitation of the English lords.

Although far from being either an infidel or a libertine, La Fontaine had lived in extreme carelessness with regard to religious concerns. However, when in 1692 he was seized with a dangerous illness, the priest who attended him is said to have prevailed upon him to suppress a dramatic piece, which was just going to be offered for representation, and to make a solemn apology, or falanx, in presence of a deputation of the members of the academy, for the publication of his tales. The singularity of his appearance and habits was such as to pass for stupidity among the vulgar, or with those who were not intimately acquainted with his character. The nurse, who attended him during his illness, observing the fervour of the priest in his exhortations to the sick man, exclaimed: "Ah, my good Sir, don't plague him so; he is rather stupid than wicked." He died at Paris in the year 1695.

La Fontaine is generally accounted one of the most original writers of France. His fables are esteemed as master-pieces in that species of composition, and stand unrivalled by any writer of his own, or of any other country. Ingenious thoughts are there unfolded with admirable clearness and simplicity, clothed in language at once easy and graceful, and adorned with all the charms of a brilliant versification, while the most profound moral maxims and reflections are delivered in a style divested of digression, and seem to arise naturally, and without effort, out of the narrative.

His tales, which are borrowed for the most part from the Italian novelists and romance writers, are related with great humour and vivacity; but it is to be regretted, that the subjects in general are such as admit of no moral application; and which no art can divest of a colouring offensive to delicacy. (2)

FONARABA, or Fausta Roman in Spanish, and Fons rapidus in Latin, is a town of Spain in the district of Guipuscoa. It was formerly called Oceana. It is situated in a small peninsula on the sea coast, on the left bank of the Bidassou, and the town is built in the form of an amphitheatre, on a hill, which looks to the sea, on the south angle of the Gulf of Gascony. It is well fortified both by nature and art, being defended by a strong fortress towards the sea, and on the land side by the high mountains of Jasqueval. The harbour would be deep were it not left dry by the tide. Its position, according to trigonometrical observations, is, West Long. 1° 47' 15'', North Lat. 43° 21' 36''. See Labourde's View of Spain, vol. ii, p. 249. (2)

FONTENELLE, BERNAUD DE L'EPURE DE, a French author of considerable celebrity, was born at Rouen, in the month of February 1657. His mother was a sister of the famous Cornelle; from whom he may be supposed to have inherited some portion of that literary genius for which he was distinguished.

Fontenelle acquired the rudiments of learning at the school of the Jesuits at Rouen; and at the age of thirteen, he produced a successful Latin prize poem on the subject of the immaculate conception. At fifteen, he had completed his course of studies. His father intended that he should embrace the profession of the law, which he himself had prosecuted with success; and Fontenelle actually pleaded a cause before the parliament of Rouen. But the discipline and habits of the legal profession were not congenial with his easy and indolent disposition; he resolved, therefore, to abandon these pursuits, and to devote himself entirely to literature. With this view, he accompanied his uncle, Thomas Corneille, to Paris; and commenced his literary career by the production of a tragedy, which, however, was unsuccessful upon the stage. But he bore the disappointment without murmuring; and undismayed at the result of his first attempt, he turned his attention towards other subjects, in which he was better qualified to excel.

The first production which contributed to bring him into notice as an author, was his Dialogues of the Dead; which, although written in an affected style, and objectionable in many respects, acquired considerable popularity. His Letters of the Chevalier de Her*** are much inferior to those of Voiture, and might have been suppressed without any injury to his reputation; indeed, he never expressly avowed himself the author of these letters. In his Éloges he departed from the peculiar style and character of that species of writing, and introduced ingenious thoughts and fine allusions, remote from the simplicity of pastoral life.

The two works of Fontenelle which contributed most to establish the reputation of his literary character were, his Plurality of Worlds, and his treatise on Orales. The ground-work of both of these treatises was borrowed; but his luminous and methodical genius gave clearness to subjects that were previously involved in obscurity; while the graces of his style, sometimes perhaps a little too brilliant and flowery, rendered the principles of the abstract sciences acceptable to general readers, by bringing them down to the level of ordinary understandings.

Fontenelle appears to have had a great desire to distinguish himself as a writer for the stage; and after having failed to obtain the success he expected from his tragedy, he attempted the composition of operas; but of all his dramatic productions, the opera of Peleus and Thetis, which was first represented in 1689, is the only one which had merit sufficient to preserve it from oblivion. While yet a young man, he took an active part in the controversy which then agitated the literary world, respecting the comparative merit of the ancients and moderns. Fontenelle declared himself an advocate for the latter; and his conduct in this dispute is thought to have proved an obstacle, for some time, to his admission into the Academy,—an honour which he at length obtained in the year 1691. During a pe-
rival of nearly 60 years, he contributed to support the
celebrity of that illustrious body, by the propriety of
his moral conduct, and the splendour of his literary
character. He was also admitted a member of the
Academy of Sciences in 1697; and two years after-
wards, when the constitution of that learned society
underwent some change, he was clothed with the title
of perpetual secretary, and became one of its most ac-
tive associates. His history of the Academy of Sci-
ences, and the elations which he pronounced upon sev-
eral of the most eminent academicians, afford ample
proofs of his talents and acquirements, and of his zeal
for the interests of learning. He embraced the prin-
ciples of Descartes; and continued faithful to the theory
of vortex, after the introduction of the Newtonian sys-
tem had deprived it of almost all its adherents.
Fontenelle died at Paris in the year 1757, having
lived nearly one hundred years. For this uncommon
longevity, he appears to have been indebted to a very
extraordinary constitution of body and of mind. At
his birth, he was thought so extremely delicate, that
doubts were entertained whether he should live. In
his youth, he avoided every kind of bodily and mental
fatigue; abstained from every sort of diversion that
demanded an effort of strength, and spent the whole
course of his life in a series of studies and pleasures
equally tranquil. His mental constitution was no less
singular. He seemed totally divested of passion; was
never irritated by censure, nor elevated by praise;
never transported by joy, nor depressed by grief; and
he is said to have never laughed nor wept. If this
constitution deprived him of some pleasures, it also
preserved him from many evils; and it enabled him to
attain an extreme old age, without suffering much from
the infirmities incident to that period of human life. (z)

FORESTAFF, the name of a clumsy instrument
long ago exploded, for taking the altitudes of the heav-
Eny bodies at sea.
FORFAR-SHIRE, one of the maritime counties of
Scotland.

1. Natural History.—The county of Forfar, known
also by the name of Angus, is situated on the east coast
of Scotland, immediately to the north of the estuary
of the Tay, between 50° 27' and 56° 59' of North Latitude,
and between 0° 14' west, and 0° 46' east of the meridian
of Edinburgh. It is bounded on the south-west and
west by the county of Perth; on the north-west by Aber-
deenshire; on the north-east by Kincardineshire; on
the south-east by the German Ocean, and on the south by
the Frith of Tay. The line by which it is divided from
Perthshire is very uneven, and extends from Kingudie,
to the westward of Dundee, in a northerly direction to
the source of the Isla. The division between this coun-
ty and Aberdeen shire is chiefly marked by the Water
shed; the ground containing rivulets running northward
to the Dee belonging to the latter, and the ground with
rivulets running southward into the Esk or the Isla to
the former. The North Esk divides the lower part of
the shire from Kincardine. It contains 977,979 English
square miles, or 496,230 Scottish acres.

This county, possessing both maritime; inland, and
alpine districts, has every variety of aspect and climate.
In the high grounds, among the Grampian mountains,
where the snow is seldom long absent, even in the sum-
mer months, the air is cold and piercing. In the inland
districts, the climate is mild and genial; and the same Forfashires,

might be said of the places along the coast, were they
not occasionally visited with easterly breezes, previously
chilled by the cold of Scandinavia. Several registers of
the weather have been kept in different places in this
county, in which the quantity of rain, and the state of
the barometer and thermometer have been recorded with
accuracy. One of these registers kept at Belmont, in
Strathmore, twelve miles north-west from Dundee, and
two miles distant from any eminence, indicated the fol-
lowing quantities of rain, in inches and decimals, during
six years.

In the year 1790 31.4
1791 37.1
1792 38.4
1793 39.5
1794 39.
1795 36.6

During the three first years of the preceding period,
the following appears to have been the state of the bar-
ometer and thermometer:

Mean height of the barom. in the year 1790 29.59
1791 29.61
1792 29.59

Mean height of Fahrenheit's thermom. 1790 41°
1791 42
1792 42

Another register kept at the Crescent, half a mile west
from Dundee, on the banks of the Tay, and 40 feet above
its surface, indicated by the rain-gauge and thermometer
to follow:

Although there are many springs in this county, none of
them can be considered as remarkable, either for the
quantity of water which they discharge, or the mineral
substances which they hold in solution. A few springs
of the chalybeate kind are resorted to by persons labour-
ing under diseases arising from debility of the organs
of digestion. The principal springs are, one in the neigh-
bourhood of Montrose; another at Wormhills, to the
south-west of Aberbrothick; and a third at Dumbarrow,
in the parish of Dunichen.

Formerly there were few parishes in which lakes did not exist; now the number of these is greatly reduced.
A few have been drained, in order to increase the extent
of the arable ground; but by far the greatest number,
containing fine shell-marl at the bottom, have been drained,
in order to obtain that valuable manure. The lake
called Lenthathen loch, situated amidst the Grampians,
and in the neighbourhood of most magnificent scenery,
is nearly of a circular form, about a mile in diameter,
and yields to the botanist several rare plants. Loch Lee,
another of the Grampian lakes, is about a mile in length,
and a quarter of a mile in breadth. In the more level
parts of the county, we meet with the lakes of Forfar
and Runcorie; and among the Sidlaw hills, those of Lun-
die, Balshardy, and Pittendreich. These are well stored
with trout, pike, perch, and eel.

The principal rivers in this county, or waters as they Rivers,
are provincially termed, are, 1. The North Esk. This river takes its rise from Lochlee, whose waters are sup-
plied by many small streams, which flow from the neigh-

Hills and valleys.

The surface of this district is greatly diversified in its appearance. On its northern and western limits, the Grampian mountains rise in lofty grandeur, and exhibit all the varied scenery of an alpine country. They are here termed the Bress of Angus, and in some places possess an elevation of nearly 3000 feet. To the south of the base of the Grampians, and at the distance of four or five miles, another range of hills appears, with a character less bold and majestic, known by the name of the Sidlaw hills. These are to be considered as a continuation of the Ochils, as they are composed of the same materials, observe the same direction, and exhibit, with these, an almost uninterrupted continuity. This range does not greatly exceed 1000 feet in height above the Tay. It traverses the whole extent of the county from Montrose to Lundie. Amidst the Grampian mountains, and even among the Sidlaw hills, there are numerous valleys, which add beauty to the scenery, and give fertility to the district. But these valleys appear as nothing, when compared with that extensive plain situated between the Grampians on the one hand, and the Sidlaw hills on the other, called Strathmore, and sometimes termed by the natives the How of Angus. This great valley runs parallel with the Grampians from their commencement in Dunbartonshire, to their termination on the borders of Aberdeenshire. This great valley, in which the hand of the manufacturer will ere long dig a canal, and spread the sail of commerce, is scarcely elevated 200 feet above the level of the sea. It would appear from the stratified hills of gravel which here and there appear, and from all the other phenomena of the valley, that it was the basin of an extensive lake, fed probably by many of those streams which at present flow through other districts, owing to the changes which the Grampians have undergone by the hand of time.

The county of Angus presents to the mineralogist a fine field for the display of his powers of investigating nature. No less than four classes of rocks make their appearance: The primitive, the transition, the flœttz, and the alluvial.

Primitive rocks.

The rocks of the primitive class are granite in small portions, gneiss, mica slate, and clay slate. The granite presents several varieties, with respect to the size of the grain, and the colour of the felspar. In some instances it is fine-grained, and bears a close resemblance to the granite of Aberdeen. The variety termed Pierre graphique, and a still more uncommon variety, in which the felspar assumed a rose colour, were observed by Colonel Imrie. This granite occupies the centre of the Grampians, and appears to be the fundamental rock. It contains rock crystal, called Caïnogranit, and topaz. Gneiss is a very prevalent rock in this district. It rests upon the granite, and is fine-grained, compact in its texture, and usually of a grey colour. It contains in several places beds of hornblende rock. Mica slate is by far the most abundant rock. The mica which it contains is termed sheep's siller. It seldom contains garnets. Granular limestone is by no means of rare occurrence; and were the Highlanders disposed to burn it, they would soon improve their pastures. Peat is at hand, and answers well as fuel for the purpose. Clay slate occurs in the less elevated districts; but in these strata no good beds of roof slate have as yet been discovered, owing probably to want of skill and industry. These primitive rocks are traversed by veins of porphyry, consisting of a basis of compact felspar, with crystals of felspar, and grains of quartz. These veins are from 8 to 10 feet in breadth, and although occurring at considerable distance from one another, yet they all observe the same direction. They stretch nearly from south to north. Lead glance has also been found in veins among these rocks. It was formerly wrought to a considerable extent near the old castle of Innermark, and yielded a sixty-fourth part of silver.

In descending from the Grampians towards the valley of Strathmore, the transition rocks make their appearance. They consist of grey whacke slate, in which the schistose character is more or less distinct, and the imbedded grains of quartz more or less numerous. In this slate numerous elliptical masses of jasper occur, in some cases extending to 30 feet in length, and 10 in breadth. The slate likewise contains nests of slate spar. Compact felspar occurs in beds of considerable magnitude, of a reddish brown colour, and a conchoidal fracture. Several varieties of trap rocks also present themselves, under the forms of greenschist and basalt. Limestone also occurs of a darker colour, of a less crystalline structure than the primitive limestones, and is much traversed by veins of quartz and limespar. The older members of this formation alternate with the newer portions of the primitive class, and constitute the fundamental rock of the flœttz class, which we are now to consider.

The flœttz rocks of this district, although they present flœttz a great variety of composition, may all be referred to the old sandstone formation of Werner, as red sandstone is the prevailing rock. The red sandstone is, in some cases, fine grained, and answers for architectural purposes; and, in other instances, it passes into gravelstone, or a rock composed of water-worn pieces of the more ancient strata, imbedded in a basis of sandstone, or ferruginous clay. The sandstone is frequently in the form of slates, or flags, and is much used for the roofing of houses and pavements. Limestone is likewise common in this district, and in several places is quarried, and burnt for economical purposes. It is commonly in the form of limestone conglomerate, a condition which appears peculiar to the limestones of the old red sandstone formation. Besides these rocks, there are extensive beds of trap, provincially termed scurric, under the form of greenstone, basalt, amygdaloid, waece, clinkstone, felspar, and porphyry. These rocks are traversed by veins of limespar and heavy spar, and frequently contain traces of copper ores. These flœttz rocks rest upon those of the transition class; and, at their southern extremity in Fife, support the strata of the coal formation.

The alluvial strata, as may be expected from the variety of surface, are very different in appearance and composition. On the summit of the Grampians, there is either a light gravelly soil formed from the decay of the primitive rocks, or the moisture of the air in those ele...
Bostryx has far added the growth of the tribe of plants termed Musci, that extensive strata of peat moss have been formed even on the summit of the highest hills. This substance is likewise common in the inferior districts in those places where lakes have formerly existed. As an article of fuel, in a country where there is no coal, it is of first-rate importance. Marl, principally of the kind termed shell marl, is very common in Angus. It is found in beds under peat moss in old lakes, and is extensively employed as a manure. When laid on grass ground, it promotes the growth of clover, rye grass, and other nourishing plants; but when employed as a manure for raising grain, it is found to thicken the husk, of oats in particular, in a remarkable degree. The shells in the marl, are those which are still to be found in plenty in the neighbouring pools and ditches; Lymnea putris, Planorbis albus, and Cyclas cornuta. The prevailing soils are light, gravelly, and of a red colour. Strong clay soils rarely occur. The soils derived from the trap rocks are usually fertile, of a dark colour, and by some would be termed loam.

There is perhaps no county in Britain, where plants have been investigated with such laborious industry, and such happy success, as the county of Forfar. It was the birth-place, and latterly the permanent residence, of the late Mr George Don, whose knowledge of the localities and habits of the plants of Scotland, and of Forfarshire in particular, was never equalled, and who added more new species to the British Flora than any of his botanical predecessors or survivors. From his list of the native plants of Forfarshire, published along with the agricultural survey, where a scientific botanist will find a storehouse of facts, we extract the following observations. On the mountains of Clova, the botanist will find a rich harvest of the rarest kinds of alpine plants; the Saxifraga pedatifida, Ranunculus alpestris, Eriophorum gramine, Salix repens, Hieracium diurnalum, and Potentilla opaca. Among the cryptogamous plants, he will find the Grimmia Donniana, (named after Dr Don, who first observed it,) Dicranum pygmaeum, Leucidea fumosa, Urechitum diamantum. In the lower grounds, he will find the Junceus Forsteri, Allium carinatum, Hypnum crispa-eastrensis, Riccia fruticulosa, and Jungermannia scalaris. On the sea shore, he will meet with the Elymus arenarius, Carex divisa, Allium ampeloprasum, Equisetum variegatum.

The zoology of Forfarshire presents fewer varieties than its botany. Mr Don has given along with his list of plants, a list of the animals of Forfarshire, which is respectable in point of magnitude, but in point of accuracy cannot be depended upon, as his knowledge of animals was vague and inaccurate. Among the quadrupeds, we may mention the hedgehog, to prove, that it extends further north in Scotland than Mr Pennant was aware of, for he restricted its northern limits to the river Tay.

Among the birds, we may number the dotterel, (Charadrius morinellus,) which visits the foreground of the Grampians about the beginning of April, and continues about three weeks, before going to the high muirs to breed. It returns about the beginning of August, and after resting again for three weeks, it retires to the south, and is not seen again until the following spring. Among the mollusca, we may notice the Unio marginata, or pearl-bearing mussel, as being found in the alpine rivers; and in the rocks on the shore, the Maja suborbicularis. The sands of Barrie furnish the Echinus pusillus; and the sea lute adhering to the lobster cages, will yield the student of nature the Scuticularia lichenata, and dimus.

2. Civil History.—In ancient times, this county was united with the Mearns, and seems to have received the name of Horrestia from Tacitus, in consequence of the mountainous aspect of its northern boundaries. It was, however, disjoined from the Mearns by Kenneth 1. about the year 833, and bestowed upon his brother Kenes; and from this circumstance, it was termed Angus. But as Forfar is the county town, it is now more generally known by the name of Forfarshire. It is at present divided into fifty-six parishes, distributed into five presbyteries, which meet at Forfar, Dundee, Brechin, Meigle, and Aberbrothick. These five presbyteries, together with the presbytery of Fordoun, constitute the synod of Angus and Mearns.

The greatest part of the estates are here held by charter from the crown, and are termed freehold. In some cases, the property holds of some proprietor or corporation, and in this case the granter of the charter is termed the superior, and the holder of the lands the vassal or feuan. But in this county, the superior claims no right to the personal services of his vassal, who merely improves his waste grounds, and in return obtains a grant of a perpetual lease. Leases of twenty or thirty years duration are frequently granted, convertible at the option of the occupant into a feu, upon payment of double rent at any time during the currency of the lease. Many estates in the county are held under deeds of entail. The object of these deeds is no doubt to keep up a name, but they reduce the proprietors to the condition of mere liferenters, chill all ardour for improvement, and hurt in no inconsiderable degree the interests of the country. The valued rent, by which the right of freehold and other public matters are regulated, amounts in sterling money to £14,303. From the best information which Mr Headrick could obtain, it appears that in 1808, the gross rent of lands, woods, quarries, fisheries, &c. in the county, and including farms in the natural occupancy of the proprietors at a reasonable valuation, amounted to £208,924 15 3.

Estimated value of house rents . 95,872 0 6

Total rent from fixed property . £304,796 15 9

The number of freeholders at present on the roll, freehold amounts to about 115. There are five royal boroughs, derels.

FORFAR, DUNDEE, ABERBROTHER, MONTROSE, AND BRECHIN. (See these articles.) Before the Union, each burgh sent one or more commissions, according to its wealth and population. Since that time, Forfar and Dundee have been united with Perth, Cupar in Fife, and St Andrew's, in choosing a representative; while Aberbrothick, Montrose, and Brechin, have been joined to Inverness and Aberdeen. The mode of proceeding is as follows: Each town council having fixed upon the person it wishes to represent them, sends a delegate to the returning borough instructed to vote for him. Each town is the returning borough by rotation, which it is of the greatest importance to gain, because in case of a division, where only four are joined, it has two votes.

The population of Forfarshire, in 1808, amounted to Population. 24,087 families, containing 45,461 males, and 53,666 females, making a total number of 99,347 souls. In the year 1811, the population had increased 8451; and at that period amounted to 107,578. The cause of the excess of females in the preceding enumeration, must be sought for in the numbers of young men who enter the
Farfarshire.

The number of hands employed in the pursuits of agriculture, may fairly be estimated at 20,000, without taking into account the great numbers who are occasionally employed in seed-time and harvest, and in weeding and hay-making during summer. About two-thirds of the county are considered arable, a 26th part under woods and plantations, and the remainder either consisting of mountainous pastures or sandy wastes. The farms vary much in point of size, some scarcely exceeding 20 acres, while others extend to 800 acres. The rent is by no means in proportion to the quantity of ground occupied; and therefore we select the following statement from Mr. Headrick, to point out the relative value of the different farms, arranged according to the rents paid.

Number of farms whose yearly rent is under £20, 1574.
Do. from £20 to £50, 366.
Do. from £50 to £100, 682.
Do. from £100 to £300, 315.
Above £300, 86.

Total number of farms, 3222.

The farm-houses of this county were formerly mean and wretched; now they are neat and comfortable. The bult and the ben have been exchanged for more fashionable, and, in this instance we must admit, more convenient apartments. Some of the houses are still built of clay, which, when properly wrought, is no mean substitute for stone and lime. In general, however, they are built of red sandstone or whinstone, and sometimes roofed with thatch, or blue slate, or sandstone flag. On a farm of from 100 to 200 acres, there is a dwelling-house built with stone and lime, of two stories, often lathed and plastered on the inside. The offices commonly form three sides of a square, built of the same materials, and of size corresponding to the extent of the farm. The ordinary duration of a lease is 19 years, and in some cases two years longer. The rents, in general, are paid in money: where grain is paid in rent, it is usually converted into money at the fair prices. In many parts, the farms are under the most judicious management, while, in some of the higher districts, ancient prejudices and habits still prevail. It would be difficult to enumerate the different kinds of grain raised in the county, any farther than by barely specifying the kinds. Wheat has been long cultivated here, and formed a considerable portion of the rent paid to the ancient monastery of Aberbrothick. It has been known to weigh 17 stone 3½ pounds English, per bushel. White wheat is the variety generally preferred; red wheat, although it yields a heavier crop, is more liable to disease. Spring wheat has been tried, but without success. Bear, here called Chester, still occupies the higher districts, and has been displaced by another species, probably its inferior in several essential qualities. Barley is universally cultivated in the best improved districts. It sometimes weighs 22½ stones Dutch per bushel. It is in common use as barley-meal and as pot-barley. Oats are here raised in considerable quantities. Several kinds are cultivated, such as the common or Angus oat, Blairnie oat, barley oat, potato oat, Dutch oat, and the grey oat, which last at least is a distinct species. The potato oat has been known to weigh 17 stone Dutch per bushel. Rye is cultivated only on thin sandy soils, which are unfit for raising the more bulky and profitable crops; such occur at Montrose, Panbride, Barry, and Monifieth. Flax is still raised in the county in considerable quantity, although not to the extent which might be considered expedient. Hemp is never even attempted. The manures principally employed are, farm-yard dung, lime, marl, and sea-weed.

The ancient breed of horses was the small sheltie or garrow, and this breed still remains nearly pure and unmixed among the Grampian mountains, where numbers of horses are required to convey home from the mountains winter fuel, and to perform other operations where there are either no roads, or those very steep and rugged. In the lower districts, bordering on the Grampians, these have been greatly increased in size, in consequence of being provided with better food and warmer shelter. In the more fertile districts, the Lanarkshire breed prevails. It is calculated that there are 9000 horses in the county, and these are estimated at £290,270. The black cattle are principally the old Highland kind; and, where attention is paid to the dairy, the more improved breeds have been introduced. Among the Grampians, from four to six Scot. pints of milk each day is the usual quantity; and, in the more fertile districts, from eight to ten pints is the general average. Sheep abound in many districts of the country. The mountain sheep, in an unmixed state, may be found among the Grampians. The black-faced or Linton are more numerous. Besides these, small flocks of the Bakewell, the Cully, or the Cheviot breeds, are to be seen in the parks of the gentry. At least two breeds of swine are found here, which may be regarded as natives. Rabbits are by no means attended to as their importance demands. The roe and the stag still exist in the county; and the fallow deer has protection in one park.

The manufactures of this county are numerous and important. Among these, the manufacture of linen stands in the first rank. On an average there are about 11 millions of yarns stamped annually, the greatest part of which is exported from the county. Dependent on the manufacture of linen, are several extensive bleachfields and spinning mills. The county likewise possesses several excellent harbours, as Dundee, Aberbrothick, and Montrose. There are two custom-houses, the one at Dundee, having the jurisdiction of the ports in the Tay up to Newbury; and the one at Montrose has the superintendance of the port of Aberbrothick. To the port of Dundee belong 147 vessels; to Aberbrothick 56; and to Montrose 67. The whole tonnage of the county amounts to 21,859 tons.

The coast of Angus abounds with every useful variety of edible fish. The cod, the haddock, the flounder, and turbot, are in abundance; and yet the quantity taken is by no means great. In the Tay, salmon are caught in considerable numbers, and sent to the London market packed in ice. Lobsters are obtained on different parts of the rocky coasts.

There are many excellent roads in Farfarshire; and roads there are abundance of materials for keeping them in repair. The only bridge deserving of notice is the one over the North Esk, which connects the parish of Montrose with the county of Mearns. It was built by subscription, to which government granted very liberal aid.

FORFAR. 

Forfar, a royal borough, the capital of the county of Angus or Forfar, stands in the great valley of Strathmore, of which it commands a very rich and extensive view to the west; and the prospect is terminated by the Sidlaw and Grampian mountains, some of which may not be less than 50 miles distant. In all writings respecting the patronage, titles, &c. the parish is designated Forfar Rents. The latter is the name of a priory, two miles distant from the town, and formerly surrounded by a lake, which is now drained; the name of which is supposed to be expressive of the purpose for which it was built, viz. as a safe repository for the charters of the monastery of Jedburgh.

In ancient times, Forfar was honoured with the residence of majesty. The ruins of a palace, or castle, are still to be seen on the top of a mount, which rises about 50 feet above the level of the plain. Here Malcolm Canmore held his first parliament, in the year 1057, immediately after the recovery of his kingdom from the usurpation of Macbeth. A figure of the castle, cut in stone, forms the device of the seal of the borough, though nothing but rubbish now remains on the spot where it once stood. The lake of Forfar, formerly stretching two miles in length from east to west, and half a mile in breadth, and covering the palace on the north, afforded a plentiful supply of water, and added to the strength of the place. About 50 years ago, this lake was drained of 16 feet perpendicular depth of water, by which a very great quantity of moss and marl has been gained yearly. About a mile in length, and a quarter of a mile in breadth, of various depth, from 2 to 22 feet, still remains, and adds much to the beauty of the town. This lake proved fatal to the murderers of Malcolm II. in the year 1056. Having perpetrated the bloody deed in the castle of Glamis, about five miles distant, they attempted to cross the lake upon the ice, which gave way under them, and they all perished. Their bodies were afterwards found; and it being ascertained that they were the murderers of the king, they were hung on gibbets by the highway.

During the usurpation of Cromwell, a detachment of his forces pillaged the town, and burnt all its public records. By that wanton deed, every written memorial of its antiquities perished. The only charter which the town now possesses, is one granted by Charles II. after his restoration, confirming all its former rights and privileges. One melancholy evidence, however, of the ignorance and superstition of the times, still remains. From the record of trials, it appears, that nine women were condemned and burnt here for witchcraft betwixt the year 1650 and 1692. The witch-bridle, as it is called, by which they were led to execution, is still preserved. It is made of iron, in the shape of a dog's collar, with two pikes on the inside. The pikes were put into the mouth, and the collar tightly buckled round the head. To the collar is affixed an iron chain, by which the unhappy sufferers were conducted to a field adjoining to the town, which is still pointed out as the place of their execution. Another remarkable fact in the history of this borough, is, that it obtained an act of the Scottish parliament, in the reign of James VI., changing the weekly market-day from Sunday to Friday. At what time it was changed from Friday to Saturday, is not known.

The borough is governed by a provost, two bailies, twelve councillors, and four deacons of crafts, who represent their respective corporations. All are chosen annually, and the council thus constituted consists of nineteen members. In order to the election of these office-bearers for the year, some days before Michaelmas each magistrate names five Burgess, who, with the four new deacons of craft elect, make up the number of nineteen additional electors; and by these thirty-eight the new magistrates and council are chosen. It may, and often does happen, that the number of electors falls short of thirty-eight, or twice nineteen; because, if any of the old members die before the end of the year, and if one or more of the old deacons be re-elected, there are no substitutes for them on the list. But if all the old nineteen be alive, and if four new deacons be elected, the number of electors must, by what is called the set of the borough, amount to thirty-eight. The twelve councillors may be annually re-elected; the provost and bailies too may thus be members of council for life. None of them, however, can be elected to the office of magistracy oftener than three successive years in one series. But, after having been one year out of office, and returning to the rank of common councillor, or private citizen, each may be re-elected for a new series of three successive years.

The council has the privilege, in conjunction with the town councils of Dundee, Perth, St Andrews, and Cupar in Fife, of electing a representative in parliament. The revenue of the borough is from £800 to £1000. It is the seat of a presbytery, and of the courts of justice; and the place where the freetholders and commissioners of supply meet for transacting the business of the county. On a maer adjoining to the town several fairs are held throughout the year, which are well-frequented; the custom of which was many years ago purchased by the town council from the Earl of Strathmore. From Martinmas to Candlemas, a weekly market, free of custom, is held on the street every Wednesday, for the sale of fat cattle; and during the seed time there is one weekly, on the same day, for the sale of work horses. These tend to increase the revenue of the borough, while they afford much accommodation and benefit to the surrounding neighbourhood.

Manufactures have in this town kept pace with their progressive improvement in every other town in the county. About the year 1745, the manufacture of Osnaburgh, or brown linen, was introduced. From a very small beginning, it has grown into a considerable trade; is now the staple manufacture, and for many years past has contributed greatly to the prosperity and rapid increase of the population of the town. The history of the introduction of this manufacture is curious. It was brought to Forfar by a gentleman, who afterwards acquired by it a comfortable independence. His brother, a weaver in Arbroath, about the year 1768, having got a small quantity of flax, unkit for the kind of cloth then usually brought to market, made it into a web, and offered it to his merchant as a piece on which he was willing to lose. The merchant, who had been in Germany, instantly remarked the similarity betwixt it and the fabric of Osnaburgh, and with difficulty prevailed upon the weaver to attempt other pieces of the same kind. The experiment, however, succeeded to his wish; and a company was soon afterwards established at Arbroath, for the purpose of conducting the new manufacture, from whence the discovery was brought to Forfar. Of late years, Osnaburghs, of the best quality, denominated Stretls, have been manufactured for the London market, with sheetings of all breadths, British duck, Germans, &c. The quantity about 2,500,000 yards annually, the average value of which may be estimated considerably above £100,000.

Forfar has been long celebrated for brewing good beer. About twelve years ago, one establishment was formed, and afterwards another, for brewing porter.
These have succeeded well. For two or three years past, indeed, on account of the high price of barley, less business has been done than for years preceding. But now, when grain is likely to assume a fair medium price, it may reasonably be expected that those breweries will extend their trade, as formerly, beyond the supply of the town and its immediate neighbourhood.

Various other improvements have of late years been carried on, which have contributed to the embellishment of the town, while they enhance the public spirit of the inhabitants. Among these we may mention a botanic garden, the work of the late Mr George Don, who was well known, and justly celebrated in the botanic world. One of his sons is said to inherit his genius, which had also received some culture under his care. The garden is replenished with a great variety of rare indigenous and foreign plants. A nursery, too, of about nine acres, under the care of an intelligent and active proprietor, is an ornament to the town, and promises to be extensively useful to planters, being filled with all kinds of fruit and forest trees, and situated in the middle of a rich and improving country. A large and commodious church, on an elevated situation, was built in 1790, which accommodates from 2000 to 3000 hearers; and last year (1814) it was ornamented with a steeple 150 feet high, which arrests the eye of the traveller in every direction, and is deservedly admired as a very elegant structure. The population of the town and country parish is about 5000. A small society of Scottish Episcopalians, and another of Antiburgher Seceder, form the only dissenters; and it is worthy of being recorded, that not fewer than 2100 annually partake of the Lord's supper in the established church. There are three public schools; two endowed by the magistrates and council, and one by them and the heirs of the parish. They are now to be placed in systematic arrangement, under the care of one of the teachers as rector; and accommodated with a suit of new apartments, which will form an additional ornament to the borough, and exhibit an additional proof of the good taste and public spirit of the managers of the public funds.

Forfar, from its inland situation, fifteen miles from the coast, is subject to many disadvantages; but if a canal to Arbroath, some years ago projected, shall open an easy and cheap access to the sea, it may rise to a degree of prosperity which it has not hitherto attained. (A. P.)

FOREFURTUE. See LAW.

FORGE. See IRON.

FORMIC ACID. See CHEMISTRY, p. 60.

FORMOSA, called by the Chinese Taï-ouan, and by the natives Koboski and Gadaus, is an island subject to China, lying between 22° and 25° North Lat. and between 5° and 5° East Long. from Pekin. It is situated about 30 leagues from the coast of the province of Fo- kien; and is above 80 leagues in length from north to south, and nearly 28 in breadth from east to west. Though lying within so short a distance of the continent, it does not appear to have been known to the Chinese till the year 1430, nor for many years afterwards did they avail themselves of the discovery. It was merely visited in 1561, by the commander of one of their squadrons, when he subdued the little islands of Pongho, which lie about midway between it and China. In 1582, a Spanish ship sailing from Macao to Japan, was wrecked on the coast, and brought the first accounts of the country to Europe. About the year 1620, a Japanese squadron left a party on the island, in the view of returning to effect its subjugation; but, in the mean time, a Dutch ship having touched there in its course from Japan, it appeared to be so eligible a station for a commercial establishment, that they built Fort Zeeland in 1634, and thus secured part of it to themselves.

In 1661 they were driven from the settlement by the celebrated Chinese pirate, Tchin-tchi-kong, or Coxinga, (See CHINA, Vol. VI, p. 233,) who made himself master of the western part, and held the sovereignty of the island during his life; but, in 1682, his grandson Tchin-ke-sun, submitted to the authority of the Emperor Kang-hee; and the island, since that period, has been tributary to China. By a chain of mountains running from north to south, it is divided into two parts, called the western and eastern provinces, the latter of which is still occupied entirely by the native Indians, and the former contains the settlements of the Chinese. It is subject to the Viceroy of Fokien, but a governor with a large detachment, generally of 10,000 men, resides constantly on the island. Taï-ouan, the capital city and the seat of government, is situated on the south-west coast in 23° North Lat. and 3° 32' 50' East Long. from Pekin. It is a large and populous place, full of trade, and equal to several cities of the first class in China. The streets are remarkably straight, about 40 feet broad, and some of them are a full league in length; but they are badly paved, and the houses meanly built of clay and bamboo, and thatched with straw. On account of the excessive heat of the sun, the streets are covered, during seven or eight months of the year, with awnings, which leave nothing to be seen but the shops on either side, in which various kinds of merchandise, ranged with the greatest order and show, present a rich appearance to the eyes of the passenger. The town has no walls or any kind of defence, unless a large edifice, built by the Dutch, and protected by four demi-bastions, may be considered as a fort. The harbour is good, but its entrance is becoming daily more difficult. The city is said to contain every necessary of life and article of traffic; both foreign commodities, such as Chinese and Indian cloths, silk stuffs, porcelain, and European goods; and also the productions of the island, cotton, hemp, rice, sugar, salt, tobacco, dried stags flesh, fruits of all kinds, and abundance of medicinal herbs.

The western province contains, besides the capital, a number of smaller towns and populous villages, in which the Chinese permit none of the native inhabitants to reside along with them, except those who act in the capacity of slaves or domestics. It appears that the Chinese population of the island would increase with great rapidity, if the government would permit free emigration from other parts of the empire; but permission to new settlers is granted with great caution, and only upon the payment of a considerable sum for the proper passports. The reason is, that the Tartar emperors are always apprehensive of a revolt among their Chinese subjects; and the proximity of this island to China, would render it a favourable field for the operations of malcontents. The district, which the Chinese possess, consists of extensive and fertile plains, watered by numerous rivulets, which flow from the mountains towards the east. The climate is temperate, except when the
FORMOSA.

...sun is vertical, and the air is serene and pure, cooled even in the hottest season with constant breezes. The soil is in general mountainous, but naturally productive. Besides most kinds of grain, which it yields in abundance, there are found in the country the principal Indian fruits, such as orange, lumbas, cacao-nuts; guavas, papaws, pineapples; and many of those which are common in Europe, particularly peaches, apricots, figs, grapes, pomegranates, water melons; cinnamon, sugar, pepper, camphire, tobacco, are also among the ordinary productions of the country; and the mountains contain mines of gold, silver, copper, and sulphur. There is no good water to be found in the whole island; and strangers are said to suffer greatly from its bad qualities. There are fewer bears, sheep, goats, or hogs, on the island; but the inhabitants breed a great number of oxen, which they train for the purpose of riding; and, being early accustomed to this kind of service, they are said to go very securely and expeditiously. Domestic fowls are reared in great plenty. The finest deer wander in large herds through the country. Tygers, leopards, monkeys, and every kind of game, abound in the forests; and the rivers furnish abundance of fish.

The Indians inhabiting the western division are entirely subject to the Chinese governor, and pay a regular tribute in grain. They compose about forty-five villages, most of which are found in the more northern quarter of the province. In each village is stationed a Chinese officer, whose duty it is to learn their language, and to superintend the collection of the impost; but these agents of the government often act in such a tyrannical manner, as to occasion the defection of the inhabitants, who have sometimes been driven to unite themselves with the independent tribes in the eastern part of the island. Even those which are most submissive to their invaders, still retain some of their ancient institutions; and in every village three or four of the most upright and intelligent old men are chosen as judges and rulers, who have the power of determining all disputes, and disobedience to whose decisions would be punished by perpetual banishment from the community. In these villages, subject to China, and which are the most populous, there is a great degree of civilization; and the houses are built and furnished after the manner of the Chinese. They are clothed with the skins of the stags, which they kill in hunting; and wear on their heads caps of a cylindrical shape, made of palm leaves, ornamented with a succession of crowns one above the other, and surmounted with plumes of feathers from the cock or pheasant. The dress of the women exactly resembles that of the men, except that their clothes are longer, and their heads more furnished with finery. But the southern or eastern islanders are still in a most savage state; and their habitations are mere earthen huts, without any piece of furniture, having only a kind of hearth in the centre upon which they dress their victuals. They are remarkably dirty in their manner of eating; and generally devour the flesh before it is half dressed. Whatever they prepare is placed on a plain board or mat; and having neither plates nor spoons, they make use of their fingers for conveying it to their mouths. They have no better bed during the night than fresh gathered leaves; and no other covering through the day than a piece of cloth, which hangs from the middle to their knees.

They subsist chiefly upon rice and the produce of the chase. Their favourite weapons are lances, which they throw with the greatest dexterity and precision to the distance of 60 or 80 feet. They use also bows and arrows, with which they can kill a pheasant on the wing with as much certainty as a European sportsman could with a fowling-piece. They run with such surprising swiftness, that they can almost outstrip the fleetest greyhound, a degree of agility which the Chinese ascribe to a custom which they have of confining their knees and reins with a close bandage, till the age of 14, but which is, more probably, owing entirely to their constant practice in hunting, and to the estimation in which the qualification is held. Those who are most swift and skillful in the chase, are distinguished by the honourable privilege of having figures of flowers, trees, or animals punctured on their skin; and the more ordinary decorations consist in wearing bracelets, or crowns made of shells and crystal, and in staining the teeth with a deep black colour. The matrimonial connections of these islanders are remarkably simple and unconstrained, especially when compared with those of their Chinese neighbours, and are left entirely to the choice and arrangements of the young people. When a youth has fixed his affections, he appears for several days with a musical instrument in his hand, hovering around the place where the young woman resides. If she is pleased with his personal qualifications, she comes forth and joins him, when they settle together their future union. They then give notice of their intention to their parents, who prepare the marriage feast, which is always held in the bride's habitation, with whom the husband remains during life. He transfers his filial duties to his father-in-law, and devotes himself to the support of the new family, of which he has become a member. Hence the natives of Formosa offer vows chiefly for female children, who procure their son's in-law to be the support of their old age. These people are represented as destitute of religious notions and worship, and as guided by the pretended predictions of a set of priestesses or female jugglers; but other accounts seem to imply, that they are not without some ideas of the soul's immortality, nor so deficient in civilization and ingenuity; and many of them are said to retain a considerable portion of Christian knowledge, which had been communicated by the Dutch settlers. There is, in fact, very little known respecting the eastern, or as it is sometimes called, the southern part of the island and its inhabitants; and the accounts both of the Chinese and Dutch writers are filled with stories so obviously fabulous, as to discredit their whole testimony. Some of these accounts bear, for instance, that one of the natives was seen who had a tail above a foot in length, covered with red hair, and resembling that of an ox, and who declared that all the inhbitants of the southern districts were born with similar appendages; that the men do not marry till they are fifty years of age, and that their wives are not suffered to bring forth children till they have passed their thirty-seventh year, and should any of them prove pregnant before that period, the priestess is summoned to produce abortion by treading on their womb. One of the most extraordinary of these histories, and which was afterwards acknowledged by its author to be a mere romance, was published about the year 1710 by the noted Psalmanazar.

In consequence, it is supposed, of the sulphur mines in the mountains, which run across the middle of this island, it is subject to frequent earthquakes; and in the year 1702, one of these shocks was attended with a tremendous novelty of the kind as to threaten the total destruction of the Chinese settlements. See Grozier's Description of China, vol. i.; Collection of the Voyages of the Dutch East India Company, vol. v.; Du Halde's History of China, vol. ii.; and Univ. Mod. Hist. vol. viii. and x. (9)
FORRES, a town of Scotland, in the province of Moray, is situated on a rising ground, about a mile to the east of the river Findhorn, and two miles from its mouth. The houses are well built, but the town contains no public buildings of importance. On the summit of Cluny-hill, a quarter of a mile to the east of the town, a monument has been recently erected to the memory of Lord Nelson. It is a lofty octagonal tower, about 70 feet high, and having a base 24 feet in diameter. It is surmounted by a battle-ax and a flagstaff. The castle of Forres was situated at the west end of the town. About a quarter of a mile to the north-east of Cluny-hill, on the road to Findhorn, stands the celebrated obelisk called Sweno's Stone, which is composed wholly of sandstone, though it is said that there is no quarry of the same stone nearer than fifteen miles. It is about 23 feet high, 3 feet 10 inches broad, and 1 foot 3 inches thick, and is said to be 12 or 15 feet below the ground. "On its east side," says the author of the Antiquities of Moray, "are two different divisions, each occupied by variously sculptured ornaments. At the top are a number of beautiful Gothic ornaments; and in the first division underneath, are nine horses, with riders, marching in order. In the next, is a line of warriors brandishing their weapons. The figures of the third are now much defaced. In the fourth, several men, armed with spears, seem to guard a number of human heads under a canopy; the bodies appearing to be piled upon the left of the division. A body of horse appears in the fifth division, and these are followed by men on foot; the first line having bows and arrows, the other three swords and targets. In the lowest division now visible, the appearance is of horses seized, their riders beheaded, and their heads thrown under an arched cover. The west side of the obelisk is chiefly occupied by a magnificent cross, and covered over with an uniform figure, elaborately raised, and interwoven with great art and accuracy, having the appearance of Tunie knots. Under the cross are two figures, supposed to represent persons of distinction, in an attitude of friendly salutation. On the north edge, are some curious carvings, below which are rows of human figures, hand in hand, in apparent unity and confidence."

In order to prevent this monument from falling down, several freestone steps were lately built round its base. The Rev. Mr Cordine, who has published an engraving of this monument, supposes it to have been erected in commemoration of the peace concluded between Malcolm, king of Scotland, and Canute, the Danish king of England, in 1002. Others have imagined, that it was erected in memory of the assassination of King Duff; and this opinion is conceived to be strengthened by the discovery of eight human skeletons laid along a trench, in a little green mount close by the obelisk, supposed to be the assassins of the king. On the declivity of Cluny's Hill, looking towards Sweno's stone, there are obvious remains of extensive entrenchments.

The corporation of Forres is governed by a provost, two bailies, and a dean of guild, who are elected annually; and it enjoys the privilege, conjointly with Inverness, Nairn, and Fortrose, of sending a member to Parliament.—Within these few years, a subscription library has been instituted by the inhabitants, and now contains a considerable number of volumes. The scenery on the river Findhorn, extending from the vicinity of Forres for nearly 20 miles upwards, is remarkable for its grandeur and beauty. The banks are for the most part rocky, and richly wooded, with every variety of form, and height, and inclination. For two or three miles below, the rock is sandstone on one side, and to this succeeds above gneiss and granite. The forest of Darnaway forms the chief part of this scenery on the left bank of the river; and opposite to it, on the right, are the properties of Refugus, and Logie, and Altyle. The first of these is matchless for its natural beauties, and has been adorned with singular taste.

Three miles north of Forres, close to the shore of the Moray Frith, there is one of the best examples of an inundation of sand which is to be seen in the island. The sand drifted from the shores of the Frith above, by the strong west winds, is accumulated in hills of considerable size, forming a chain about a mile, or a mile and a half in length, and at some parts nearly a quarter of a mile broad. The hills are often undergoing changes of form and height, but have not for many years exhibited any tendency to general diminution. About 60 or 70 years ago their increase was very great, and very sudden, the inundation burying completely, in the course of a few days, the estate of Cubin.

Five miles east of Forres, is the heath which Shakespeare is supposed to have intended as the scene of the first interview between Macbeth and the weird sisters.

There are few places in Scotland better adapted for a cheap and pleasant residence than this small town. Its climate is excellent; its markets are good; it is abundantly supplied with a variety of fish, from the neighbouring seaport of Findhorn, which is only five miles distant, and the surrounding country is rich and luxurious, and abounds in game.

The following is the population of the burgh and parish in 1811:

FORT. See Fortification, and Forts, Vitriified.
FORT-AUGUSTUS. See Inverness-shire.
FORT-WILLIAM. See Inverness-shire.
FORT-GEORGE. See Inverness-shire.
FORTAVENTURA, or Fuerte-Ventura, is the name of one of the Canary Islands. It is about fifty miles long, and from eight to twenty-four broad. The island is very low, and narrow in the middle, and is almost cut in two by the sea. The portion south of the isthmus is mountainous, sandy, and barren. The portion to the north of the isthmus is also mountainous, but contains several fertile and populous districts. The villages are here so numerous, that the traveller no sooner loses sight of one than he discovers another.

The principal towns in the island are, La Villa, the capital, which is situated to the north of the isthmus, and contains 100 houses; Oliva, situated in the middle of a fertile plain, and containing fifty houses; and Tunte, which contains about 100 houses. On the east coast there are three small sea ports, called Langa, Terrafita, and Pozzo Negro. A great quantity of goat milk cheese is made in the island, which breeds 50,000 kids, each of which weighs between forty and fifty pounds. For an account of the history, agriculture, commerce, and productions, of the Canary Islands, see Canary Islands. The position of the western point of Forta.
FORTH.

Fort, ventura, according to solar observations, is West Long. 14° 51' 15'', and North Lat. 52° 4'. (f)

FORTH. (including the arm of the sea generally called the Frith of Forth,) is the name of the largest river of Scotland, and that which has the longest course, rising on the north side of the mountain Ben Lomond, and discharging itself into the German Ocean in 55° 54' of North Latitude. The Forth, near its source, receives a small stream, and is then called Avondor, or the Black River; and, on entering the parish of Port, receives the name of Forth, which is said to signify the name. Soon afterwards it expands into a beautiful lake, from whence it is precipitated over a perpendicular rock, 50 feet high, and flows with a smooth winding course from Carrimore to Stirling bridge, 33 miles, though only 20 in a direct line. Thence, having received a considerable accession in the waters of the rivers Teith, Allan, and Dovan, it gradually enlarges to 4 miles in width at Borrowstounness, but exhibits the most singular and beautiful sinuosities in traversing a level plain, called the Carse of Stirling, where 24 miles occupied by its channel are no more than 6 miles in a straight line by land. It is next narrowed to less than two miles by the sudden projection of headlands from the two Queensferrys on its opposite sides, below which a regular expansion, little interrupted, (the Biddotria of the Romans, and now named Frith of Forth,) is resumed down to Fife- ness on the north, and St Abbs Head on the south, where it meets the German Ocean. Between these two points the distance is between 35 and 40 miles. The direct course of this river is scarcely less than 100 miles; but its sinuosities do not traverse a shorter space than 200. Its depth from Stirling bridge to the mouth is from 3 to 37 fathoms, or more, between Inch Garvie and the North Ferry it is 32; and somewhat further west, opposite to Rosyth castle, where the breadth is 3000 yards, it is 21 fathoms, whence it gradually shallows upwards. Part of the bottom is here covered with sleet or mud 20 feet deep, deposited on freestone. The tide flows a mile above Stirling bridge, or between 70 and 80 from the sea in a straight line, until it is interrupted by a rock across the channel, where stream tides rise five feet. It flows and ebbs regularly twice in twenty-four hours; but the flood and ebb run about two hours longer in the middle than along the shore, and it rises at most about four fathoms in a stream. Besides this, however, there are particular currents, or irregularities, above Queensferry, and particularly from Culross to Allan, or, beginning at the mouth of the river Carron and Borrowstounness, continue downwards. These irregularities consist in an intermission of the tide during the flood; and before high water the sea ebbs. On the contrary, while the sea ebbs, and before low water, the ebb ceases, and a new commencing continues some time; after which the ebbing is resumed until low water. This is seen during two hours, and the irregularity occupies more of the river according as it is spring or neap tide. These irregularities are well known by the name of leekies.

The principal rivers tributary to the Forth are, the Goodle, rising in the Loch of Montevieh, the Teith, and Allan, above Stirling bridge; and below it, the Dovan, Carron, Avon, Almond, Leith, Esk, Leven, Tyne, and others. There is, besides, a communication, by means of a navigable canal, with the river Clyde, which preserves an intercourse between the east and west coasts of Scotland.

It would take a long time to describe the natural productions of the Forth, and hitherto they have met with very little attention. Various cetacea, from 20 to 60 feet in length, migrate here from the northern seas; and whole shoals of grampus have accidentally stranded themselves on the shores. We learn from history, that five or six hundred years ago they also frequented this river. The porpoise is constantly seen tumbling in the water; one specimen of the beluga, or white whale, was killed in 1815, near Stirling: the sun fish is occasionally taken; and the opah, or gold fish, has also occurred. But there are others, the constant source of valuable and productive fisheries; such as salmon, herring, haddock, turbot, and oysters. A great salmon fishery is carried on at Stirling, which supplies all the neighbourhood, and allows a quantity for export. Salmon is so abundant, and so easily obtained at this part of the Forth, that the inhabitants of Stirling were, during a long time, provided with it at the rate of three halfpence a pound, which became a particular privilege, nor is it long since it was abrogated. Two fisheries on a smaller scale have recently been established on the south side of the river, at Abercorn, and near Queensferry, and their produce chiefly transmitted to the capital; and a third was attempted near the first, which had some success, at Blackness castle. Vast shoals of herring resort periodically to the Forth, and afford employment to many hands in their capture, as well as ample subsistence to the poor; but they are neither so large nor so much esteemed as those taken on the west coasts of Scotland. Nevertheless, their cheapness, which is sometimes sixpence a hundred, is of incalculable benefit to a large city, where there are many indigent inhabitants, as well as to the towns on the coast, which in general possess little wealth. The herring fishery, which has rather declined of late from the uncertainty of success, is carried on from the mouth of the river to six or eight miles above Queensferry. Haddock, cod, and turbot fisheries, are principally lower down than Leith. Skate, flounders, and halibut, are common; turbot is obtained in sufficient quantity to supply Edinburgh market at prices not immoderate, that is, from four to ten shillings, according to size and scarcity; but most of it goes to London. Some time ago, contracts were made for turbot, at two shillings each when taken, to be carried thither. Soles also inhabit the sandy bays of Aberdy and Musselburgh, but are seldom caught. This being ascribed to the unskilfulness of the fishermen, an experiment was made by others purposely brought from places noted for it; but, after repeated trials, the fishery was given up. To judge by the shells thrown up on the coast, an extensive portion of the Frith is inhabited by oysters; and accordingly, many valuable oyster beds are resorted to, for the most part to the eastward of Leith. There is little doubt, however, that there are others for several miles westward of it. Great quantities of oysters are consumed; for it is a favourite kind of food both in the sea-port towns and in the country; and there are particular rules observed in dredging, and in rejecting those of insufficient size. The beds themselves belong to different private proprietors; but some have been totally exhausted from injudicious management. The consumption of oysters is so great in the metropolis, that there are certain regulations established for conducting the market. Mussels are also collected in quantities along the shores; and while oysters are sold by numbers, they are sold by measure at so much per pint.

Many of the mollusca tribes, besides the two latter which we have alluded to, inhabit the Frith; and probably the majority are yet non-descript. Mussels, acme, nereids, are seen in great variety and beauty;
and conchology has still to receive accessions in the history of the shells which may be recovered here. Little need be said of the ornithology; for, except in the wild fowl resorting hither during winter, and in the numbers of solan geese frequently a small rocky island called the Bass, there are no peculiarities. Few phoebes are seen but on some of the rocks, and occasionally near the shore.

The minerals are more important. At first, the course of the Firth is through deep clay, and near impassable mosses. Expanding towards the east, it approaches vast strata of coal, beds of lime and ironstone, found alike on each side of the river; and some of these are not only on the banks, but penetrate far under its bottom—so far, that it is reported the workmen from the opposite coasts can hear each other's operations below, where it is more than three miles wide. Neither is this so improbable as might at first sight appear; for the coal workings from the north at Culross are said to have been carried two miles under the Firth; and from Borrowstounness on the south, they penetrate 1700 yards. The principal mines are in the neighbourhood of Alloa, which exports 35,000 tons annually; Culross, Borrowstounness, Torryburn, Inverkeithing, Dysart. Some of these mines have been open above five hundred years, and have been carried to great extent. John Taylor, the Water Poet, who published an account of his travels in 1618, expresses great admiration of the entrance to one of the Culross mines by a pit far within high water mark. The mouth of the pit was defended by a strong circular bulwark, which likewise served as a pier for vessels to load immediately from the mine itself, without land carriage. But, during some very tempestuous season, the bulwark either yielded to the violence of the waves, or the rising tide overflowed it, so as to render the mine useless ever since. It is said, that King James VI. having, by more than an ordinary effort of courage, penetrated this mine from the land side, where there was also access, and being conducted to the bottom of the pit, where he suddenly beheld himself surrounded by the sea, loudly exclaimed, "treason! treason! but an attendant, pointing to an elegant bark anchored here, endeavoured to dispel his fears; and the king preferred being carried in it directly ashore, to descending within and returning below ground. At the end of a reef stretching a mile from the shore of Torryburn, an engine has been erected, which, as its walls are enviroined by the rising tide, appears an isolated tower in the middle of the river. In addition to the home consumption, great quantities of coal are exported from both sides of the Firth, both coastwise and to distant countries. Lime is wrought to a great extent on many parts of the banks of the river, from the parish of Aberfoyle, near its source, downwards; but the principal quarry is at Charlstown in Fife, 12 miles below Dunkeld. In Fife, also, the lime which is imported into Scotland is chiefly used, but the whole of Edinburbough is supplied from places continually employed there; and the lime is exported in numerous small vessels from a harbour besides the kilns to different parts of Scotland. Being of the best quality, it is applied equally to building and the manuring of ground. In some places, the limestone rock abounds with enorghi, and, being sufficiently hard to enable it to receive a polish, is used for ornamental purposes, under the name of Fife marble. There is abundance of ironstone, either scattered about the shore in loose nodules, or dug from pits. It has partly been sent to Carron, and partly to the English foundries; but the expence of obtaining or collecting the loose nodules or septaria, has hitherto greatly diminished the profit that would otherwise result from this very rich sort of ironstone. Pieces of fine jasper, pebbles, granite, and petrifications, occur on many parts of the shore.

There are several rocks and islands scattered throughout the lower part of this river, where it has expanded into a frith, of which Inch Garvey, Inch Colme, Inch Keith, the Bass, and the Isle of May, are the principal. On the top of the first, which is barren and rocky, stands a small fort, with two inconsiderable pieces of cannon, and one invalid soldier, who is stationed there in solitude six weeks at a time. It was sometimes converted to a state prison of old, but now belongs to a private family. This island, standing in the middle of a strait, between the Queen's Ferries, could effectually prevent any hostile approaches higher up the river. Inch Colme, which scarce exceeds half a mile in length, and is narrow, enjoys greater celebrity; for one of the kings of Scotland, having escaped imminent danger, while he found an asylum on it, shewed his gratitude to Divine Providence, by erecting a monastery here in the year 1125. Its picturesque ruins are still extant. Soon after the commencement of the late war, in 1793, a battery of heavy guns was constructed on Inch Colme, which, it was supposed, would command the deep water of the Firth, but no opportunity has been afforded of trying their effect, which those who consider themselves well acquainted with the navigation of the channel have doubted. The island abounds in rabbits, and belongs to the family of Murray. Cramond Island, nearly opposite, on the south side, is connected with the land at low water, but the access, unless in a certain direction, is very dangerous, from deep mud or quicksands. The island best known, at least to the inhabitants of the capital, is Inch Keith, which lies about half way between the coasts, and somewhat eastward of Edinburgh. It is between two and three miles in circuit, of fertile surface, and has always been pastured. Circumstances have frequently rendered this inconsiderable spot of importance, from an early date, either in civil or military operations. In the year 1497, when the venerable disease was making uncommon ravages in Edinburgh, and was then, as in the rest of Europe, considered a pestilence, the magistrates directed that all persons infected with the "grand gare" should repair to the sands of Leith, where they should find boats ready to convey them to the island, "there to remain, until God should provide for their health." In the reign of Edward VI. the English sent two expeditions equally destructive into Scotland, when Inch Keith was taken and fortified. They were expelled by the French, who erected fortifications on a larger scale, consisting of a strong tower on the highest ground, with an interior court, 100 feet in diameter, as also an external wall of hewn stone, 20 feet high, and 9 feet thick, with Queen Mary's arms sculptured on it, and a motto as vertice変わり。 the whole of this island is enclosed, and is a monument descriptive of the order of the Scottish parliament. More recently, when a Russian fleet lay in Leith roads, during the last war, there was an hospital here for their seamen; and at present it has a lighthouse for the safety of mariners. The Bass is a lofty precipitous rock, with a conical summit rising from deep water, within two miles of the southern shore of the Firth, near North Berwick. This isle, which is less than a mile in circuit, is accessible only by a dangerous and narrow pathway; formerly it was employed as a state prison, and a small fortress upon it surrendered to Oliver Cromwell. It was held in property by a private family, and purchased by government in the reign of Charles II.; but after most of the kingdom had submitted to the sovereignty of Wil-
FORTH.

At the revolution, the fortress was held out by a few of the abdicated monarch's adherents, which produced an order for its demolition on their surrender. The Bass now in the hands of a subject, by whom it is leased, for a rent which is indemnified by the immemorial flocks of solan geese taken annually on it, (see Bass). The Isle of May lies nearest the mouth of the Forth, and is probably the largest of the whole, being nearly three miles in circuit, and is situated six or seven miles southeast of the town of Anstruther. It affords good pasture, and has a pool or small lake of fresh water. Anciently this island belonged to an English monastery, for the monks of which, King David I. of Scotland founded a cell or priory of the order of St. Augustine, and there was also a chapel dedicated to St. Adrian. The latter was frequently resorted to in pilgrimages, and particularly on account of barrenness, though not for that reason only, as Andrew Wood of Largo, a celebrated Scottish mariner, held certain lands in Fife for the service of piloting James IV. and his queen to St. Adrian's chapel. A lighthouse was erected here in the reign of Charles I., which has undergone many successive improvements, and receives a duty from all vessels navigating the river. Both it and the island being private property, frequently changed their owners, and having lately passed by marriage into the Duke of Portland's family, they were purchased by the Commissioners for Northern Lights in 1814, for £60,000 sterling, when affording a very considerable revenue.

There are numerous towns and harbours along both sides of the river and Firth of Forth, where trade and manufactures are carried on in various branches. Connected with Stirling, where it is crossed by a bridge of four arches, the principal towns are Grangemouth, Borrowstounness, Queen's Ferry, Leith, Musselburgh, Prestonpans, and Dunbar on the south side; and on the north, are Alloa, Culross, Charlestown, Inverkeithing, Burntisland, Kirkcaldy, Dysart, Leven, Pittenweem, Anstruther, Crail, with a few of lesser note. The number of piers and harbours is not less than thirty; and some of them of expensive construction, such as Leith, where there are considerable wet docks; there is a fine basin at Borrowstounness; and at Queensferry the most recent improvements have been adopted. But storms from the east, attended with a tempestuous sea, occasionally damage the harbours. Excepting Stirling and Leith, few of the towns contain 2000 inhabitants, and several of them not half that number. The principal manufactures are of iron, salt, pottery, sal ammoniac, some bricks and tiles, and recently Roman cement and alum have been fabricated at the village of Blackness. There is also linen made on the north side, along the coast of Fife, and soap on the south side, together with oil. Coal, lime, and grain are the chief exports of natural products; but foreign products are brought from the west by the great canal, and carried eastward; and there is a vast quantity of artillery and iron manufactures exported from the Carron foundries. The vessels belonging to the different ports are mostly occupied in the coasting trade, but whole fleets resort to the Baltic; several vessels belong to the Greenland whale fishery, and a few are engaged in West India traffic. Independent of the manufactures carried on in the vicinity of the river, cotton, linen, and muslin goods are exported, and some groceries, wood, flax, and other commodities imported; to receive the duties on all of which there are custom-houses along both sides of the river. The chief trade, however, is conducted on the same side with the metropolis.

When the Romans invaded Britain, they found the northern parts occupied by various barbarous tribes; and to repress the incursions of those to the west, erected a strong rampart, now called Adrian's Wall, from the Firth of Clyde to the very banks of the Forth, where it terminated in the vicinity of Blackness Castle.

Here, a Roman fort is supposed to have stood; but in the reign of the Roberts, we learn from ancient record, that the site of the present edifice was a receptacle of lawless banditti, and it was probably founded about that period. It is washed by the sea on three sides, contains a deep well of fresh water, and, like the two fortresses already mentioned, was frequently converted to a state of prison. Now, there are five unserviceable cannon on the walls, of small size; and it is a place of no strength, being commanded by several improvements. Nevertheless it has repeatedly been the subject of anxious competition in the facts times of old, and is preserved as a fortification by the articles of the Union.

A more modern fort was erected between Leith and Newhaven, on the appearance of Paul Jones, a noted pirate, upon the coasts of Scotland; and still more lately, a small battery at the North Ferry. These, together with the batteries before mentioned, and a martello tower, almost finished, at the mouth of Leith harbour, constitute the principal defence of the Firth.

Besides the navigation of the Firth, for the purposes of trade, there are several regular ferries between the opposite coasts, from Stirling to Leith; and packets sail from the latter harbour to different towns, as Anstruther and Ely on the coast of Fife. Three steam boats also began to navigate from Leith upwards, in the year 1814, affording a cheap and commodious means of conveyance. But it has been proposed, at various times, to facilitate the communication with the west and south of Britain by rendering the river navigable from Stirling bridge to Gartmore, and to intersect the different curvatures of the land to the east of Stirling by a canal. According to an estimate, when this subject was particularly urged in the year 1774, by expending £13,236, such improvements could have been made, as to admit the navigation twenty miles in a direct line above Stirling bridge, by boats fifty or sixty feet long, thirteen wide, and drawing three feet and a half of water: And the navigation could be carried downwards to Alloa, six miles in a straight-line, instead of the present windings of the river, through twenty-four. Advantage would doubtless have resulted by putting the proposal into execution, but it was in a great degree superseded by the canal between the Firth and Clyde. Another project, much more singular, was made in the year 1806, to connect the opposite sides of the river by a tunnel passing under its bed. The passage between the ferries being frequently interrupted by storms, and much difficulty being experienced in the transportation of great numbers of cattle continually brought from the north of Scotland, it was thought such an improvement would remedy these inconveniences, and it was patronised by many intelligent persons. A spot, about half a mile west of Blackness Castle, where the tideway is 3839 yards in breadth, was considered the most favourable point for the south entrance; and the depth of water not exceeding thirteen fathoms and a half, rendered it preferable to the strait between the Ferries. A long time was employed by engineers in sounding and boring; but it appeared, on penetrating the bed of the river, that a sufficient roof could hardly be obtained for the tunnel, which, joined with other weighty objections, led to the dereliction of the project. See Sir Robert Sibbald's Works, Statistical Account, vol. vi. p. 21. Millar and Vazie on Tunnels. Knox's View of the British Empire. (c)
Fortification is the science that teaches the best method of putting a town, citadel, or other military position, in such a state of defence, as may enable a small number within to hold out against the attack of a great number from without, and to afford the besieged the best means of annoying and cutting off the assailants, with the least possible danger to themselves.

The origin of fortification may be traced to the inequality that has always subsisted among different states, with regard to military power. When a nation found itself attacked by an ambitious and restless neighbour, that could bring into the field either a greater force, or an equal force with greater rapidity, it would have recourse to a defensive system of warfare, taking advantage of the mountains, rivers, woods, ravines, and other natural means of protection, which the country afforded. In this way, a very superior invading force might be defeated, or at least kept in check a sufficient length of time, to allow the invaded state either to march its own armies to the point of attack, or to procure the assistance of other states, whose interest it might be to support a weak neighbour against the attacks of a stronger. Were the political divisions of the earth so arranged, that the weaker states should always have the advantages of mountains, rocks, marshes, &c. on their frontiers, their deficiency in military force would be in some measure compensated by natural fortifications. But as considerations of a very different kind have generally regulated the partition of territory, small states have not unfrequently been destitute of all such advantages. Unless, therefore, such states could supply, by artificial means, those bulwarks that had been denied them by nature, they must have been constantly at the mercy of the first stronger power that chose to attack them. We find, accordingly, that various kinds of artificial fortifications have been employed for purposes of defence; and that the construction of these has always been considered as an object of the highest importance. It is the only means of placing a weak state on a footing with its neighbours, whether its weakness arises from a deficiency in physical strength, or from the operation of moral causes.

The most obvious method of protecting an open country from sudden invasion, would be to carry a wall round the whole frontier. Of this species of fortification, the great wall that separates China from Tartary, and likewise the Roman wall in the north of England, built for the purpose of defending the southern part of the island from the sudden incursions of the Picts. But besides the insuperable objection, that, in many cases, it was utterly impossible to command the means of raising such walls, it was soon found that the difficulty of guarding such an extensive line rendered them of comparatively little use. Such methods of defence were therefore soon abandoned, or rather were seldom adopted, and, in their stead, detached fortifications were constructed at particular points, and at a moderate distance from one another. These forming a communication between the different commanding positions on the frontier, were found to possess all the advantages of one continued fortification, while they were constructed at much less expense, and defended with infinitely greater ease. An invading army could not venture to leave these places of strength in their rear, without the greatest danger of having their retreat cut off; and consequently a country, possessing such fortifications, could seldom be subject to sudden attacks. Nor is this the only advantage that is found to result from such fortified places. By making them depots for arms, ammunition, and other military stores, they become the surest protection of established governments against rebellion or any internal commotion. To the art of fortification, then, may perhaps be justly ascribed not a little of that peace and good order among mankind, which would otherwise be sacrificed to the lawless ambition of despots, or the madness of factious demagogues.

It is impossible to say at what time, or in what country, men first began to construct fortifications. In a rude state of society, when weapons of attack were few and simple, and when the success of war depended more on the physical powers, than the skill of the combatants, the ingenuity necessary to render a place impregnable, whatever might be the force of the assailants. An earthen mound, a deep ditch, or a single stone wall, would probably be sufficient not only for protecting a garrison against sudden attacks, but even for enabling it to hold out against a regular siege. How long the art of fortification continued in this simple state, we have no means of ascertaining; but it is evident, from various passages of sacred history, that it had made considerable progress in Eastern countries in the days of Moses, upwards of 1500 years before Christ. From these countries, it probably travelled to the West, where it received great improvements from the Greeks and Romans. By inventing new methods of attack, these warlike states obliged the besieged to adopt new methods of defence; and thus while they exercised their own ingenuity in the art of war, they called forth that of the nations with whom they contended. A single mound, or stone wall, was soon found to be altogether inadequate to resist the force of the engines with which they were assailed. The wall or rampart was accordingly strengthened by towers erected upon it at convenient distances, and from these the besieged were enabled to defend the intermediate parts of the wall, which they could not otherwise have done without exposing themselves to the missile weapons of the enemy. Besides these towers, the rampart itself sometimes consisted of a double or even a triple wall. Of this kind were the walls of Jerusalem and Babylon.

The most obvious method of assaulting a fortified place in rude ages, would be to construct an earthen mound or counter fortification, from which the assailants could engage with the besieged on equal terms. This method of attack was probably coeval with the art of fortification itself, as from the passages of sacred history to which we have already alluded, it appears to have been common in Eastern countries at the time of the Israelites taking possession of the land of Canaan. The same method of besieging towns was adopted by the Greeks and Romans. They constructed their circumvallation of turf, and, in some cases, they were made double at an interval of fifteen or sixteen feet. The interior wall was intended to preserve them from the sallies of the besieged, the exterior to guard them against the attacks of those who might come to the assistance of the town. The space between the walls or mounds was occupied with tents and lodges for the soldiers. These walls were surmounted with turrets;
after every tenth of which was a tower, extending from wall to wall, and equal in height to the fortifications of the town. After all, this method of attacking a place was better calculated to starve it into a surrender, than to take it by force.

Another, and perhaps a more expeditious method of attack, was by means of detached mounds or aggera, erected opposite the weakest part of the fortification. These aggera were constructed of all sorts of materials, as wood, stone, earth, &c. and gradually carried forward till almost close to the walls. The besiegers were thus raised to a level with their enemies, and sometimes succeeded in throwing bridges between the aggera and the fortification, by which the besiegers stormed the place. Still, however, this method of attack was liable to a serious objection. The laborious nature of the operations necessary in constructing even single and detached mounds or aggera, afforded the besieged time enough to strengthen such parts of their rampart as were threatened, and thus deprived the assailants of no inconsiderable part of the advantage to be derived from their works. The invention of moveable towers or turrets was therefore a very great improvement in the art of attacking. These towers were erected on wheels and rollers, by which they could easily be moved from one place to another; and, in point of size, were proportioned to the height and strength of the place to be attacked. In their most improved form, they consisted of wood, and were so constructed as to be taken down and carried about with the army as part of the baggage.

But the great difficulty of attacking fortified places in ancient times, did not consist in the prodigious labour, so much as in the danger to which the besiegers were exposed in constructing their outworks. From their situation, the besieged were enabled powerfully to annoy their enemies, with comparatively little danger to themselves. Huge stones, and other heavy bodies, thrown from the ramparts, became formidable and destructive weapons, against which the besiegers could find no protection in the ordinary means of defence. It was to prevent the fatal effects of such weapons, that the testudo was invented. This consisted of a number of soldiers, arranged in different forms according to circumstances, but all holding their shields above their heads, thus forming a canopy or covering over those who were employed in the works beneath. The testudo was also sometimes employed, for the purpose of taking a place by storm, when the garrison was not in a proper condition to defend itself. In this case, the front rank stood upright, holding their shields before them; the second held their shields above the heads of the first, at the same time stooping a little; the third stooped still more, holding their shields also above their hands; and so on to the rear rank, which was in a kneeling posture, thus exhibiting the appearance of a tiled roof. On this roof, another body of men was drawn up in the same form, and protecting themselves in a similar manner. A number of successive stories being thus constructed, those that formed the highest were enabled to engage on equal terms with the besieged, and frequently succeeded in getting possession of the place.

In later times works were constructed, and attacks made on fortresses under the protection of covered ways, or approaches. These approaches were generally the work of great expense and labour, being guarded on one side, and sometimes also on the other, with a mound of earth, and covered on the top with skins of animals, rafters, or bundles of rods, called fascines. At the extremity of the approach, was erected as close to the walls as necessary, either an agger, or a moveable tower, according to circumstances.

Such were some of the defensive works used by the ancients in carrying on a siege, or in making a sudden attack on a fortified place. Of their offensive weapons, we have already given an ample account under the articles ARMS AND ARTILLERY, to which we refer our readers. Of the methods employed by the besieged for destroying, and otherwise rendering unserviceable, the machines of the enemy, we have also spoken under the article ARCHIMEDES, where we took occasion to state our opinion with regard to the wonderful power ascribed to the mechanical inventions of that distinguished mathematician. We would only observe farther on the subject of ancient fortification, that mining seems to have been practised at a very early period, and with considerable success, especially in destroying the towers and aggera of the besiegers. The earth under these works being excavated, the place was filled with combustible matter, and set on fire. The superincumbent earth was thus rendered friable, and sinking down, the towers were overturned.

The invention of gunpowder, (anno 1330,) though ultimately destined to produce a revolution in the system of defending and attacking fortified places, was not immediately productive of this effect. When great guns began to be first used, they were so rude and unmanageable, that the battering engines of the ancients long maintained their ground. Even so late as the beginning of the 15th century, few towns had been regularly bombarded, though artificial fire works had been frequently used, sometimes in the form of rockets, and sometimes fastened to birds tails, for the purpose of setting fire to such parts of the town or camp as were of a combustible nature. It was a device of this kind, that proved fatal to the camp of the Austrians before Saaz.

About the beginning of the 16th century, the use of great guns became more common, and their effects began to be more apparent. The circumvallations of the besiegers gradually assumed the form of regular fortifications; and fortified places themselves underwent a considerable change both in form and strength. We cannot here enter into a detail of these changes, without supposing our readers to be acquainted with the principles of the art, which it is the object of this article to explain. It may, however, be observed in general, that the use of modern artillery had not of itself the effect of shortening the duration of sieges. The advantages of great guns, especially after men had acquired considerable dexterity in the management of them, were no doubt very great to the besiegers; but they also afforded to the besieged a powerful means of annoying the enemy. Besides, fortified places were sometimes so successively strengthened, as for a long time to defy even the force of the heaviest ordnance. A wall at Magdeburg, received 1550 cannon shot without sustaining any damage. The numerous instances too, which history affords of long and unsuccessful sieges, even after the invention of fire arms, prove that this invention was not more advantageous for attacking than for defending fortified places. The siege of an important place was almost decisive of the fate of the war, and if not successful on the part of the besiegers, generally terminated in the loss of the greater part of their army.

Such was the state of fortification, when, towards the end of the 17th century, M. Vauban effected a complete revolution in the art. This celebrated engineer invented a new method of attack introduced by the mode of defence hitherto adopted has been able to hold.
be the means of defence which the garrison still possesses. Such a system appears to be an agreement entered into among belligerent powers, to deliver up to one another fortified places at a certain price, and certainly has a tendency to suppress that fortitude and determined spirit of resistance, which the history of ancient, as well as of some modern sieges, has proved to be the chief cause of a long and successful defence.

In the remaining part of this article, we shall endeavour to lay before our readers a complete account of the modern plan of fortification, with the art of attacking and defending fortified places. In this account we shall take an opportunity of noticing the various improvements which have either been proposed, or actually adopted; and among others, the plan of defence recommended by Carnot, who has long been distinguished by mathematical, political, and military talents, and well known for his famous defence of Antwerp, in 1813.

PART I. ON THE CONSTRUCTION OF FORTIFIED PLACES.

SECT. I.

Permanent Fortifications.

Every fortified place is in the form of a polygon, more or less regular according to circumstances. The sides of this polygon may be considered as chords of the arches of a circle described about the place, and on the relative length of these chords the strength of the place may, in particular cases, very much depend. The lines which form the plan of the fortification, as described on the ground or on paper, are called the traverse, and the height to which it is carried the relief.

In Plate CCLVII. Fig. 1, is exhibited the trace of a regular fortification of five sides, in which DEFHG is called the exterior, and KLMN the interior polygon. The distance from A to the angle of the exterior polygon is called the great radius, and from A to the angle of the interior polygon the small radius. The part contained between two radii, as EBCF, is called a front of the fortification; and a line dividing any of the works into two equal parts, as AE, a capital line. The fronts of fortifications consist of bastions and curtains. A bastion is the part about the angle of the polygon, as VUFZ. The curtain is that part of the front which joins the bastions, as BC. In the bastion VUFZC, the lines VU, ZC, are called the flanks; and UF, FZ, the faces. Bastions which have no flanks, but have their faces produced till they meet the curtain, are called redans. This difference gives rise to the two methods of fortification: the bastion system, and the system of Tenailles, or perpendicular fortification.

When an angle is turned from the place, as F, it is called a solait angle, and re-entering when turned towards the place, as C. The angle F is called the salient, or flanked angle of the bastion. U, Z, the angles of the shoulder; and V, C, the angles of the flanks, or re-entering angles. In redans, the angle formed by the face and the curtain is called the flanking angle, or angle of the tenaille. When the shoulders of the bastion are built in the circular form P, Q, they are called orilons, or tours creuses. The distance between the angles of the flanks, as VC, is called the gorge of the bastion; and CM, or MV, the demi-gorge. A straight line, drawn from the salient angle of one bastion to the angle of the flank in another, as FB, is called a line of defence. If this line be drawn along the face, and parallel to it, it is called a racing defence; and if the line make an angle with the face, the defence is said to be fachant, or oblique. When the line of defence meets the curtain short of the extremity, the part of the curtain between that point and the extremity is called the second flank.

The whole circumference of the works about a town, as represented in Fig. 1, is called the enceinte, or corps de la place. Other works have each a particular name; but they are in general called outworks. The chief strength of the corps de la place, as well as of the outworks, is a mound of earth called the rampart, and of which the trace shows the thickness at the bottom. On the top of the rampart is raised another mound, called the parapet, for the purpose of covering the besieged and their guns from the fire of the enemy. Behind this, are two or three steps called banquets, on which the soldiers stand when they fire over the parapet; and between these and the town, is a passage called the terreplein, of sufficient breadth for the movement of troops, and the conveyance of cavalry from one place to another. The rampart is generally lined with a wall, called a revetment, on the top of which is a passage round the parapet of about two feet in breadth, called the way of rounds. The sloping surface of a work is called the escarpe, if it declines from the place; and if it inclines towards it, the counterscarpe.

Before the rampart in all works, is a ditch called the fossé, made by excavating the earth for the rampart. Round the counterscarpe of this ditch, and at a convenient distance from it, is cut out a passage called chennin-converti, or the covered way. From the parapet that defends this, the ground declines by a gentle slope towards the field, and is called the glacis.

The command of a work is its height above the field, or above some other work, and is not to be confounded with relief, which is the height above the horizon. When a fortification has only a partial command of the field, it is called a razing fortification; and when it is much elevated above the ground, it gets the name of a high fire. If any part of a fortification cannot be seen from the parapet, it is called a dead angle.

The profile of a fortification, is a vertical section of the works from the extreme boundary of the glacis.
FORTIFICATION.

Permanent Fortification.

Various rules have been laid down by different writers, for determining the most advantageous proportions of the parts now defined. The following were given by L'Erard:

1st. That the salient angle of the bastion should never be less than 60°, and always 90° when practicable.
2d. That a flanking and a flanked part should be within musket shot of one another, viz. from 700 to 900 feet.
3d. That every part of a fortification ought to be flanked, or seen from some other part.
4th. That all flanking parts ought to be so strong, as to resist the force of ordinance.
5th. That all the works of a fortification ought to be so proportioned in elevation, that the one nearer the place shall be higher than the one before it.

Notwithstanding the excellence of these rules, however, the practice of L'Erard was very defective. He left all the lines to be determined by the constructor; the flank was given, but varied with the sides of the polygon, and, on irregular ground, was difficult to be traced. It was also too small, and rendered less easy to be defended, from being perpendicular to the face. Succeeding engineers corrected these faults, by determining the various parts with more precision, and on more accurate principles. The improvements which followed, were adopted partly in one country, and partly in another, and thus gave rise to the different methods known by the French, Italian, Spanish, and Dutch. These methods, however, may be considered as essentially the same, the difference among them being chiefly in the salient angle of the bastion, and the form of the flank.

Whatever method of fortification be adopted, it is of importance to observe, that all the works ought to be traced out in the exterior polygon. If they are traced on the interior, the different points will not be determined with the same accuracy. Having promised this, we proceed to lay down the rules for the most approved method of fortifying as it is now practised.

The gorges of the bastion should never be less than from 160 to 200 feet wide, so as to afford a free communication with the bastion, and room for mounting two or three guns.

The length of the flank depends on the length of the line of defence, and what it is required to defend; but it ought never to be less than from 180 to 200 feet, and should be perpendicular to the face which it is intended to flank.

The orillon should never be larger than to allow two or three guns to be placed on the covered flank. If it be more, it weakens the flank.

To increase the offensive power of the flanks, guns have sometimes been placed in vaults cut out of the rampart beneath. These vaults are called casemates; but they have been objected to on account of their diminishing the strength of the flank, their annoying the gunners with smoke, and being very expensive. To remedy these defects, and, at the same time, to reap the advantages of an auxiliary fire, lower flanks have been constructed before the other flanks, and below the orillon. In these the ordnance is covered by a parapet, and the ammunition is placed in a vault under the parapet of the higher flank. Compared with casemates, these lower flanks are undoubtedly an improvement, but, at the same time, they certainly diminish, in a considerable degree, the effect of the higher flank.

and it may therefore be justly questioned, how far they are, in many cases, advantageous.

The salient angle of the bastion ought never to be less than 80 degrees, and if it could be made to exceed 90, it would give to the whole work a still more advantageous form. The flanked angle would be thus enlarged, the flanks lengthened, the faces more parallel to the field, and the bastions themselves might be at a greater distance from one another.

The length of the faces is determined by that of the curtain and the side of the polygon, but in no case ought it to be more than 550, or less than 220 feet.

The curtain should never exceed 500 feet, nor fall short of 200.

The depth of the ditch or fossé generally depends on the nature of the ground, and the quantity of earth required for the rampart. Its width must also be determined by circumstances, but ought never to exceed 100 or 150 feet. The ditch ought always to be dry when there are no outworks.

The covert way is of great use in preventing the enemy from approaching too near the ditch, and obliging them to be more watchful in guarding their works, while, at the same time, it enables the besieged the more easily to defend their outworks, as well as to collect their troops in safety when they intend to make a sally. The covert way is parallel to the countergarde of the ditch, and varies in breadth from 30 to 40 feet, according to circumstances. In all cases, it should be of such a width as to allow the troops to form and manœuvre without disturbing those who may be defending it. In order to give every part of the fortification a complete command of the glacis, the angle which the plane of the latter makes with the horizon, ought to be such, that if the plane were continued, it would pass through the highest part both of the outworks and the enceinte.

The space A in the re-entering angle of the covered way, is called a place of arms, of which the faces or lines forming the salient angle are from 60 to 100 feet wide. A similar space in the salient angle of the covered way, is called the salient place of arms. Such places were found to be of great use in defending the covered way, and when were the most rendered much more so by surrounding them with a ditch distinct from the covered way, and on the escape of that ditch constructing a rampart for the defence of the men within. In the demi-lune, this form, the work is called a demi-lune or ravelin, as ADCB, Fig. 2. The original design of the demi-lune was principally to defend the gates of the fortress and CCLVII, the bridge before them, so as to prevent either from being taken by surprise. By enlarging their size, however, they were found to be more extensively useful, and have long been considered as essentially necessary for all curtains. Their principal advantages are obstructing the enemy's view of the bastion, and commanding the glacis, so as to prevent the erection of works in two positions very advantageous for attacking both the flanks and faces.

Some engineers have preferred placing the demi-lunes before the bastions, as better calculated from positions of their size to retard the progress of the besiegers, and affording, from their position, the means of flanking the works constructed by the enemy for attacking the faces and flanks. This position, however, is liable to several objections. It leaves the gates, curtains, and even the flanks more exposed. The communication with the rampart is less secure, and from the difficulty of flanking them, the demi-lunes themselves are easily taken. By modern engineers, they
have accordingly been completely rejected.

In the construction of demi-lunes, some have given them their defence from the curtain, as ADC, Fig. 2, where EE, GH are from 48 to 60 feet, and the faces of the ravelin 130 to 180. Others have taken the defence from the orillons, as IDK, where the faces are from 200 to 250 feet. Sometimes also they have been constructed in the form LDM; but all these forms are inferior to what will be described afterwards.

Demi-lunes are surrounded in the same way as the enceinte, with a ditch and covered way, the former being 48 to 60 feet wide.

A second enceinte, called the fausse-brave, has sometimes been constructed around the first, having a terre-plein of from 16 to 24 feet on a level with the field, and defended by a parapet. This work doubles the fire of the enceinte, and, from its low and grazing direction, affords a better defence to the covered way and fossé. It scarcely holds out, however for any length of time after the glacis is taken, and is besides liable to many objections. It assists the enemy in mounting a breach, and the deserters in making their escape; affords shelter to the enemy's reinforcements, and covers their miners while at work. It was formerly much used by the Dutch, but, in modern fortifications, is seldom adopted.

The method of tracing out a fortification as described above, has undergone many changes, and received considerable improvements since the time of Errard. Of the engineers who immediately succeeded him, Pagan occupies the first place. That writer having witnessed all the wars of Louis XIII. soon perceived that the method of defending places, had by no means kept pace with the art of attacking, and was, in consequence led to introduce considerable changes into the position and arrangement of the different works. He fortified on the exterior polygon, the side of which he determined to be from 900 to 1150 feet. From the middle point of the side, he erected a perpendicular towards the centre of the place, from 120 to 170 feet. Lines drawn through the extremity of the perpendicular to the angles of the polygon determined the faces, which he made from 170 to 340 feet. The ditch was parallel to the faces, and 90 feet wide, and the faces of the ravelin were directed to the angles of the shoulders. The ditch before the ravelin was 55 feet, the covered way 30; and the faces of the places of arms 48 to 60. He also laid down as a rule, that the line of defence should not exceed 750 feet, terminating at the extremity of the curtain, and at right angles to the flank.

Vauban, who may be regarded as the father of the present system of attack, also made considerable improvements in the method of defence. In his trace, the perpendicular is determined by the length and number of the sides of the polygon. If the enceinte be a square, the perpendicular is one eighth of the side; if a pentagon, one seventh; and if a hexagon or upwards, one sixth. The faces are determined as in Pagan's method, and are made equal to two-sevenths of the side. The flanks are at right angles to the line of defence, and the orillons, which are curved outwards, one third of the flanks. The most advantageous length for the side of the polygon is fixed at 1250 feet, and 1000 for the line of defence. This construction possesses considerable advantages over the method adopted by Pagan. It can be more easily adapted to local circumstances, as all the parts diminish with the side and angle of the polygon. The flanks have an advantageous position, and the bastions are more spacious.

Vaughan also introduced a change in the construction of cavaliers or mounds of earth raised above the rest of the fortification, for the purpose of commanding a distant part of the field. Formerly these had been placed in the curtain and various other parts of the fortification, and were sometimes used for defending the curtain. In these positions, however, they were found to embarrass the manoeuvres of the soldiers. Vauban, therefore, enlarged their size, and placed them in the bastions, whence they could more effectually defend the curtain. They are traced thus: A parallel 90 feet from the interior of the parapet, denotes the exterior side of the talud or slope of the escarp, and 18 or 20 feet farther back, is drawn the fire-line or interior side of the cavalier. In small bastions, the talud is almost perpendicular, and the earth is prevented from falling down by a revetment. This revetment, however, ought in no case to be higher than the parapet of the bastion, that it may not be seen by the enemy, and that the garrison may not be injured by the splinters. It is also a disadvantage attending cavaliers of this kind, that they prevent the bastion from being intrenched farther back. Nor is this defect remedied by carrying a parapet, as some engineers have done, from the cavalier to the bastion, and constructing a ditch before it, as such a parapet is destroyed as soon as a breach is made. A more advantageous method of constructing cavaliers will be given in a subsequent part of this article.

The improvements which Vauban introduced, were not confined to the enceinte alone. He also made several advantageous alterations in the construction of outworks, though, it must be admitted, that he left not a little to be done in this way by his successor Carnotaine. The first outwork used by Vauban, is the tenaille A C T, Fig. 3. It is placed before the curtain, and separated by a ditch sufficiently large to receive the earth that may fall from the curtain, and which might otherwise fill the terre-plein. Of course it, in a great measure, supersedes the use of the fausse braye. In his first tenailles, Vauban used flanks, as b e, g f, though they were afterwards omitted. In constructing tenailles of this kind, h i, f e are parallel to the curtain, the first at 16, and the last at 60 feet distance; a k, t t, 30 feet from the flanks of the bastion; a b, t g, equal to one-half of a C or t C; and the flanks b e, g f, parallel to those of the bastion. Having determined a b e, and t g f, there are drawn parallel to these, and at the distance of 54 feet, a k h and t t l for the interior side of the terre-plein. Thus the terre-plein of the faces and flanks of the tenaille is 30 feet, but that of the curtain only 18.

In constructing tenailles without flanks, which are found to be most advantageous, the flanks being easily destroyed, the faces a b and t g are continued till they opposite the centre of the curtain. By this form, the tenaille is not endangered, and the besieged may retain it even after the fossé is taken. The form would be still farther improved, if, instead of forming an angle a C T, it were parallel to the curtain. It would thus afford a direct fire on the terre-plein of the ravelin, and allow the ditch to be made larger.

The tenaille answers several important purposes. It covers the sides of the curtain and flanks, by which the besieged communicate with the ditch; preserves a communication with the ravelin, and secures the retreat of those who defend it; protects the men in the fossé when dry, and the boats when wet; affords a raising fire on the enemy when crossing the ditch, and covers the revetment of the curtain to a certain height. It is also of great use in case of a breach being attempt-
This is a text about fortification, discussing the work of Vauban and his improvements in the field of fortification. It covers topics such as demi-lunes, ravelins, bastions, and the construction of fortifications. The text also mentions the work of engineers like Belidor and Montalembert. It discusses the importance of the salient angle and the use of parapets, terre-plein, and glacis in fortification. The document is likely part of a larger work on military engineering and strategy.
33 to 40 feet, without embarrassing some part of the service. Perhaps 36 feet is the best medium.

To prevent the rain lodging upon it, the surface of the terre-plein should incline towards the town at the rate of one inch of perpendicular descent in every foot of breadth. It ought also to be planted with rows of trees, particularly oak and elms, for the purpose of supplying wood for the artillery engines and carriages. The rampart is to be finished towards the town by a talus or slope, not, however, so steep but that the soldiers may ascend it without being obliged to go round by the rumps or passages leading up to the terre-plein. Between the houses and the rampart, there ought, if possible, to be a street 14 to 20 feet wide; and if there is not space sufficient for this otherwise, the inner side of the rampart may be made more nearly perpendicular, and be supported by a revetment. It is always inconvenient to have houses close to the rampart, and ought therefore, if possible, to be avoided.

Engineers have differed in opinion with regard to the construction of bastions, some recommending the full, others the empty. The former are those in which the ground within is level with the rampart, the parapet only being higher; the latter are such as have the ground considerably lower. The empty bastions, it is said, afford facilities to the garrison for carrying on their mines, and the interior space is well adapted for magazines. The full bastions, however, are now generally preferred, except in cases where there is a scarcity of earth, as they are better calculated to resist an assault, while in the empty bastions the magazines are much exposed to the enemy's shells, and the entrenchments within are incapable of a great resistance.

The principal work constructed in the bastion, as formerly mentioned, is a cavalier. The most approved form of this work is represented in Fig. 3, where E, F denote the terre-plein of the bastion 36 feet in breadth, \( w x y a \) line parallel to the faces of the bastion, and forming the escape of the faces of the cavalier, from which it is 30 to 36 feet distant, and GH the parapet. The copues \( z w, z y \) are perpendicular to the faces, and 20 to 30 feet distant from where the face of the ravelin terminates on the face of the bastion. These copues cover the terre-plein, from which alone the work can be taken. The communication between the cavalier and the interior, is by means of steps behind the faces, so placed as to be covered from the enemy's fire.

Another kind of cavalier called a barbette, is sometimes constructed in the salient angle of the bastion \( a \), extending about 36 feet along the faces. The terre-plein of the barbette is about 24 lower than the parapet of the bastion; 24 feet in breadth, and has ramps at each end, for bringing the guns upon it. The chief advantage of the barbette is, that their fire may be directed to any point where it may be most effectual in annoying the enemy.

As the object of the parapet, in all works, is to cover the besieged on the rampart, it ought to be of a sufficient height and thickness for that purpose. It has been found that a twenty-four pounder fired against a parapet, at a short distance, penetrates about 11 feet in hard ground, 13 in middling, and 16 in loose earth. A parapet therefore ought to be from 18 to 20 feet in thickness. The practice of raising the revetment as high as the parapet is now abandoned, and the exterior talus or slope is finished with gavons or turf, having a base equal to its height, or half its height, according to the nature of the materials. The interior of the salient angle is sometimes made circular, to admit a greater number of men than it could otherwise do. The height of the parapet above the terre-plein ought to be 7 feet 6 inches, and the banquette about 3 feet; that is 4 feet 6 inches lower than the highest inner edge of the parapet. When the banquette is higher than 2 feet, it ought to be provided with steps for the soldiers to ascend. Its breadth should be about 4 feet, to allow two ranks of soldiers to act. As a banquette is not on all occasions useful, it may sometimes be sufficient to have a mound of earth behind the parapet, ready to be constructed should it be necessary.

In order to give the fire of the garrison a complete Plunge of command of every part of the field, and the enemy's parapets, the works, the parapet has a slope outwards. To determine this slope, which is called the plunge, is always a problem of great importance. If the parapet be too level, the guns of the garrison cannot be brought to bear on such of the enemy's works as are very near; and should the slope be very great, it weakens the upper part of the parapet. The plunge, that is the vertical difference between the interior and exterior edge of the parapet, should not therefore if possible exceed 18 inches, but, at the same time, it ought to be so constructed as that the garrison may completely command the covert way and glacis.

The guns of the garrison are fired through openings in the parapet, called embrasures. These openings are not made when the parapet is at first constructed, but generally left to be cut out as the position of the enemy's batteries and other circumstances may require. The form of embrasures has undergone various changes, but that now generally adopted is from six to nine feet in width towards the field, and from 16 to 18 inches towards the place. The best method of supporting the sides of the embrasures is by means of saucions or large fascines. Wood and stone are sometimes used, but are dangerous on account of the splinters. The part of the parapet between two embrasures is called a merlon. Revetments should never be carried so high as to interfere with the embrasures; nor should trees be planted near them, as the roots become very troublesome. When, from a scarcity of earth, it becomes necessary to construct the whole or any part of the parapet of masonry, it ought to be from four to seven feet in thickness.

In former times, it was usual to carry a passage round the outside of the parapet, on the top of the revetment, from 6 to 10 feet wide, with a wall from three to six feet high towards the field, in which were loop-holes for the soldiers to fire through. This passage, commonly called the passage of the round, is now completely abandoned, having been found to afford considerable facility to the enemy in making an assault. Garrisons, or small towers before the salient angles of the parapet, for sentinels, have also been given up.

As a free communication among the different parts of the fortification is of the greatest importance, it becomes necessary to have ramps or slopes, by which the artillery, &c. may be brought upon the rampart. If the bastion be full, ramps in the gorge will be sufficient; if empty, one will be required at each flank, at the faces, and also at the curtains. The breadth of the ramp may be from 10 to 19 feet, according to circumstances; and its perpendicular ascent, from 1 inch to 2½ inches per horizontal foot.

Souterrains, or casemates, are places constructed under the rampart, for the purpose of lodging the soldiers;
and containing ammunition, &c. The invention of shells has rendered contempos much more necessary now than they were in former times. They are most advantageously placed in the curtains and cavaliers, as being least exposed to the enemy's fire. Their sizes are different, according to the purpose for which they are intended. Such as are intended for powder-magazines, ought to be in a dry place, and as far as possible from buildings. It is calculated that 18 tons of powder occupy a space of about eight cubic yards.

Gates, in a fortified town, should be as few as possible, to save the garrison unnecessary duty, and to prevent the expense of keeping bridges in repair. Gates are generally placed in the curtain; and, according to Carnot, ought to be 9 to 10 feet in width, and 13 to 14 in height. They are shut by a draw-bridge, and also by a strong door at each extremity of the passage. On the right and left of the gate, and within the town, are watch-houses for centinels, which ought to be shell-proof. Formerly, the bridges before the gates were of wood, but in the new fortresses they are of stone. The former had the advantage of being easily burned, in case of emergency.

In those curtains that have no gates, there are subterraneous passages called posterns, which communicate with the ditch by two flights of stairs or ramps. They are useful in holding ammunition for the outworks. The extremity next the field ought to be covered by a tenaille, or closed up by a very strong gate. Engineers have differed in opinion with regard to the comparative merits of a dry and a wet ditch. There can be no doubt, that one capable of being made either dry or wet, according to circumstances, is to be preferred; at the same time, it seems to be generally admitted, that a dry one is the more advantageous, particularly if the enceinte has a revetment. It not only enables the garrison to lend more prompt and effectual assistance to the outworks, but it also encourages the defenders of these to maintain their position with more obstinacy, knowing that they have a ready and safe retreat in case of extremity. Besides, it is only in a dry ditch that the garrison can make sorties, the communication by means of boats being altogether unfit for rapid movements.

In a dry ditch, the communication between the fortress and the ravelin consists of a passage b, Fig. 3, about nine feet wide, and inclosed by a parapet on each side, terminating in a glacis. A passage of this kind is called a caponnier. When they have a parapet only on one side, they are called half caponnières. Both kinds are sometimes carried between the shoulder of the bastion and the ravelin, as well as between various other parts of the fortification, and are useful in defending the ditch. They are always perpendicular to the lines which they enfringe.

In moist ditches, which are intended to be dry, it is frequently necessary to have a small ditch called a cuvette, for carrying off the superfluous water. It is also sometimes used to prevent the enemy from surprising a work that has no revetment or wet ditch. In this case, it is 8 feet deep, and 12 wide.

If a place be so situated, that a current of water can be brought through the ditch at pleasure, it gives the garrison a prodigious advantage over the besiegers, and always obliges the latter to be very cautious how they cross the ditch for the purpose of making an assault. In order more effectually to inundate the ditch, dams or batardeaux, a b c d, Fig. 1, are sometimes employed. They are constructed of stone, and of a sufficient thickness to resist the pressure of the water contained in them. The water is admitted and discharged by means of sluices, from which it flows over a long slope, so as not to injure the bottom of the ditches.

Bastardeaux ought to be constructed in places as much as possible without the reach of the enemy's fire; and the sluices ought to be well protected. When the bastardeaux is constructed before the curtain, it serves as a communication between the place and the ravelin, by means of a gallery in the interior.

Tenaille are generally 50 feet in width, having a parapet on the escarpe, and a terre-plein of 25 feet. Underneath, they have posterns similar to those in the rampart, in the outer extremity of which may be constructed a convenient harbour for small boats, when the ditch is wet. In the gorge of the tenaille, on each side of the postern, is a flight of stairs.

Demi-lunes are called simple when the interior is plain and empty, and composed when they have reduits within, composed. A simple demi-lune consists of a parapet only, or a rampart, with a parapet upon it. The width of this rampart ought to be about 50 feet, which will leave 30 feet for the terre-plein, after a parapet has been constructed. The ramps of the terre-plein are in the salient angle. Demi-lunes are sometimes furnished with posterns, which serve for a communication with the places of arms when the ditch is wet, and for sally ports when the ditch is dry. They are generally in the salient angle. The gorge of the demi-lune ought to have a revetment with a small harbour, and ramps or stairs.

The redut of a demi-lune ought to have a rampart Dimension of 50 feet wide, with a parapet, and ramps at the extreme of its faces. If the ditch before it be dry, it ought to be from 9 to 12 feet higher than that of the enceinte. The stairs between the two ditches ought not to reach to the bottom of the lowest, lest they facilitate the attack of the enemy. The communication for the garrison may be completed by wooden stairs, to be removed when not to be used. On the ramparts of demi-lunes and reduits, trees ought to be planted, as formerly mentioned, with regard to the body of the place. They render it more difficult for the enemy to effect a lodgement there. In the salient angles of the ravelins, there ought always to be barbettes; and the counterscarp should have a revetment of from 10 to 12 feet.

With regard to the communication between the higher and lower parts of a fortification, it may be observed, in general, that ramps are more advantageous than stairs, the latter being more easily destroyed. Sometimes, however, it is impossible to have ramps.

Traverses ought to be about 10 feet in thickness. Traverse, with two passages, one towards the glacis, and another in the counterscarp. To prevent the covered way from being enfiladed, the glacis has a crotch c d e f. Traverse have in general banquets, from which the covered way is defended, which are as high as the crest of the glacis. Sometimes the banquet is carried across to the counterscarp, leaving only one passage at the extremity of the traverse next the glacis. In the faces of the places of arms, there are ramps to facilitate the sorties, about 10 feet wide, and so steep as to prevent their being enfiladed. These ramps ought to be at some distance from the salient angle, where they would be too much exposed. The passages from the gates through the glacis are from 12 to 18 feet wide, the sides of the glacis being lined with walls, and the whole constructed so as nowhere to expose the covered way.
It has been proposed by some to cover the glacis with stones, or plant it with brush-wood, to prevent the enemy from making excavations. Perhaps the same purpose would be better accomplished by planting it with trees. This last method was adopted by the French engineers subsequently to 1792. Another improvement in the construction of the glacis, is to round off all the angles, except such as are salient, by which means the places of arms are rendered more capacious, and the lines are less liable to be enveloped. This practice was first recommended by Fontalard.

The postern in the places of arms which communicates with the covered way, ought to look towards the bastion, because, if it were on the opposite side, it would be exposed to the enemy's fire, whenever they get possession of the salient angle of the ravelin. The communication between the covered way and the ditch is formed by ramps in the counterscarpe of the places of arms.

Such is a general outline of a complete fortification according to the modern system of defence. A fortified place, however, when finished, seldom presents so simple a form as what we have now described, being generally surrounded with a great variety of other outworks. The nature and use of these we shall now proceed to consider.

A tenaille is a kind of couvre face, Fig. 4, constructed on each side of a small ravelin B, to increase its strength, and cover the shoulder of the bastion. To trace a tenaille, produce the face of the ravelin, and, leaving from 60 to 80 feet for the fossé, set off ab equal to 180 feet. On the counterscarpe of the bastion, set off cd equal to 90 feet, and abcd will be the tenaille. Works of this kind are sometimes a little different from that represented in Fig. 4. But it may be remarked of all of them, that they are much inferior to large ravelins. They are in consequence very seldom adopted.

Counterguards are works placed sometimes before the bastion, and sometimes before the ravelin; but the latter position is now generally preferred, as they thereby answer the purpose of large demi-lunes. A counterguard before the ravelin is represented in Plate CCLXI. Fig. 1, where AB is equal to about 240 feet, and CD about 60. A counterguard before the bastion does not afford sufficient protection to the shoulder, and is, besides, one third more expensive than that before the ravelin. At the same time, it may be of essential service in that position, especially if the revetment of the bastion be very high compared with the covered way. Counterguards should have a revetment all round, as high as the terre-plein, with a fossé from 70 to 90 feet wide. It will also increase the strength of the work, to have a coupure a b before its reduit, with a fossé 20 to 24 feet wide, lined on both sides with a revetment up to the terre-plein. Under the parapet of the coupure is a postern, with stairs to communicate with the counterguard. The ditch of the coupure ought not to be so deep as the large ditch by six feet, if both are dry; but if the great work be wet, the bottom of the small ditch will not require to be more than one foot above the highest water. The revetment, from the bottom of the ditch of the coupure ought to be at least 10 feet high, to prevent a surprise in case the enemy should get possession of the place of arms E. Coupiures in general should be perpendicular to the faces, and so laid as that the enemy cannot batter them from the covered way. They should also be placed near the extremity of the terre-plein FG towards the enceinte, that the communication with the latter may be the better secured.

When there is a scarcity of earth, a ditch is sometimes constructed before the covered way, or rather before the glacis, called the avant fossé. It is not, however, of much use, unless it can be made wet and dry at pleasure, and is rather incommodious to the soldiers when making a sally.

The avant-covered-way is a second covered way before the first or before the avant-fossé; but is useful only in large fortresses, which have numerous garrisons. It is constructed in the same way as the first, care being taken that the fire of the latter is not intercepted by the former. The avant-covered-way communicates with the works behind by means of bridges or caponiers, the inner extremity of which terminates in the places of arms.

Fleches are works of two lines or faces, forming an angle, and generally constructed over salient angles. They are sometimes useful in covering a passage, but in general they are incapable of passing any resistance.

Lunettes are works resembling ravelins, but consisting only of a parapet, placed opposite the salient angle of the covered way, as H and K, Fig. 1. If the covered-way has an avant-fossé, the lunettes are placed in the fossé; but if it has none, they are constructed at the foot of the glacis, as H and K, Fig. 1. When surrounded by a ditch and covered-way, they form an excellent defence; and, by obliging the enemy to open his works at a greater distance from the place, they essentially prolong the siege. They are also useful in sorties.

Lunettes ought not to be placed too far from the enceinte; their angles should be at least 60 degrees, that it may be defended by guns; and the faces from 100 to 200 feet long. They are always of the greatest advantage, when the angles of the bastions are very open.

The most advantageous arrangement of lunettes; and that by which they best defend one another, is where the straight lines joining them make salient and re-entering angles alternately; the salient before the ravelin, and the re-entering before the bastion. In this way, too, the greatest number can be made to defend one bastion, all which must be taken before the bastion itself be assaulted. Flanks of from 50 to 60 feet are necessary in lunettes. The angles of these flanks increase as that of the bastion diminishes, and vice versa.

The communication between the lunette and the covered way, is by means of caponiers; but lest these should be occupied by the enemy, a subterraneous passage from the counterscarpe of the covered way, to the gorge of the lunette, is preferable. If the communication is not covered, it enters the gorge by steps; if it is subterraneous, the gorge is straight, and the steps are in the middle of the lunette. If the terre-plein of the lunette is not higher than the ground, the gorge must be protected by a wall with loop-holes, at least 6 feet high, and 12 to 20 inches thick. The covered way and glacis round the lunettes, are constructed in the same way as before the enceinte.

A horn work is represented by ABCD, Fig. 2, and is constructed as follows. From the salient E, produce the capital, making EF from 450 to 500 feet. Through F draw a perpendicular BC, making BF, CF each from 300 to 500 feet, and on this line construct a front, as on the exterior side of the polygon. Then draw the faces BA, CD directed to a point, about 30 feet from the shoulder of the bastion. If a ravelin abc is constructed before the horn work, its faces ought to be 200 feet. The ditch round horn works is about 72 feet. Various entrenchments, as G and H, have been
Fortification.

They sometimes have been of much advantage.

Horn works are placed sometimes before the curtain, and sometimes before the bastion. In the former position, they do not appear to be of advantage, as, in case of their being taken, the enemy becomes master of the whole front. Before the bastion they may be very useful; but in every situation they are liable to strong objections. They require a great number of men to defend them—two of which, from a salient that is not easily supported by other works—they present a straight front to the enemy, which is always weak, and they are very much exposed to an assault on their wings or faces.

Crown-works differ from horn-works in having the bastion in the middle, as Fig. 3. In other respects, they are the same, and constructed in the same way. They are, however, liable to still stronger objections than horn-works. They are more expensive, and more difficult to defend. They are therefore seldom used, unless it be to cover some large and important position near the fortress.

Detached and isolated works are such as are completely unconnected with the body of the place, and intended to protect or attack some distant position. Their form and magnitude differ with circumstances; but they are always similar to some one or other of the works already described.

Of the works placed in the ditches, or used as ca-

pones and entrenchments, the most remarkable are Montalembert's casemated caponiers, angular towers, and ravelins with si- lerons. The caponiers are large stone buildings, with two or three rows of guns above and below, and between these rows loop holes, through which the soldiers may fire with musquetry. One half of the caponiers may be used as casemates, as the smoke is easily carried off. The whole is covered with a shell-proof covering. The angular towers, or tours angulaires, are round buildings, with a stair in the middle, and places all about for men and guns. The sides are pierced with embrasures and loop holes, and the whole covered as the caponiers are, with a shell-proof covering. On the top is sometimes erected a watch-tower. Under the same denomination of works may be classed the English martello towers, consisting sometimes of several stories, with embrasures and loop-holes. The communication between these stories is by means of ladders. On the top is placed one gun, and sometimes more, the carriage of which moves on a pivot. The ravelins, with ailerons or orillons, do not differ from common ravelins, except that they are smaller, and have the orillons. The latter are sometimes constructed of stone, but more frequently of earth, and are separated from the ravelin by a small ditch. These orillons are of great use in covering the shoulders of the bastion, when the ravelin is too small for that purpose. But in every case it would be better to have a large ravelin without the orillons, than a small one with them. The orillons are in fact a sort of places of arms, which, when taken, give the enemy the command of the ravelin.

Advantages of water.

Casemates have frequently been resorted to as a certain means of defence; but besides the general objection that they are expensive, it does not appear that they are so effectual as might at first be supposed. The most useful works of this kind, are the double caponiers, for the defence of the ditches. These are covered with a shell-proof arch, and surrounded with a ditch 12 feet wide, and 6 feet below the bottom of the ditch in which they are placed. The chief object of this ditch is to prevent the enemy's approaching so near as to throw inflammable matter into the loop-holes of the caponiers.

To cover the gorge of a work, a single wall is sometimes constructed with loop-holes, and stairs behind it to communicate with the terreplein. Perhaps the best defence for any gorge, is a tower like Montalembert's, or the English Martello tower, as it serves not only to cover the work, but also to protect the men in retreating to the garrison.

When casemates are constructed, they ought to be at least eight feet in height, and as much in width, with loop-holes at the distance of every three feet, both to give the soldiers the command of the ground immediately under the work, and to allow the smoke to disperse. If the caponiers are of a considerable length, they ought to have traverses at short distances, or walls with loop-holes, that they may be more obstinately defended should the enemy get possession of one extremity.

It was formerly observed, that at a very early period, mines were employed by the besieged for overturning the towers and other works of the enemy constructed near the place. After the invention of gunpowder, this mode of attack became more effectual, and of course more common. According to the modern system, a mine consists of a small subterranean chamber or cavity, filled with gunpowder, which by its explosion destroys the works raised above or near the spot. The part containing the powder is called the fourneau, and the passage leading to it the gallery. When a work of this kind is made by the besiegers, it is properly called a mine, and a countermine when employed by the garrison. The construction, however, is the same in both cases.

When mines are to be used in the defence of a place, the galleries ought to be constructed before the siege commences, having branches running from them in various directions. The former ought to be of masonry, the latter may be constructed of timber. The works before which mines are to be cut, ought to be of sufficient strength to resist the enemy till such time as the mine be finished, if it has not been previously constructed. A mine, indeed, ought never to be used but before a strong and important work, where it is expected that the enemy will make a formidable attack. When mines are employed under an outwork for the purpose of dislodging the enemy should they get possession of it, they ought not to be too near the escape lest they should be discovered by the enemy's miner. In general, they ought to be at least 12 feet distant from the revetement of the work, and if possible lower than the ground of the fossé. The principal galleries should be from four to five feet wide, and from six to six and a half feet high. Three feet square will be sufficient for the branches. Several rows of mines before one another may sometimes be useful; but they ought not to be too near, lest the explosion of one should loosen the earth about the others.

Having pointed out the general disposition of the
The relief of fortifications.

The relief of fortifications, in general, may be observed, that the parapet of the most distant outwork ought to have the command of the field, and every succeeding one the command of that before it. All revetments should be completely covered, the covered way before the demi-lune should have a command of at least six feet, the glacis before the places of arms seven feet six inches, and the faces of the bastion so much as to fire over the salient angle of the demi-lune. Some engineers have proposed to make the rampart in every case of a determined height. Vauban fixed this at 22 feet. Some have recommended 14, and others 30. From the very nature of the thing, however, it is obvious that no such rule can be applicable to all places. The great object in every fortification is to bring as many fires as possible to bear on one point, and therefore the relief must depend on the number and distance of the outworks, the dimensions of the trace, the distance of the enemy’s parallels or trenches, and various other considerations. But as the commands or relative heights of the different works must always bear a certain relation to one another, these heights may be determined by the following proportions.

To find the height of the salient angle of the bastion.

As the distance between the salient angle of the bastion and the salient angle of the place of arms:

To the distance between the angle of the shoulder and the enemy’s third parallel before the demi-lune:

So is the height of the glacis before the place of arms + 3 feet:

To the height of the crest of the parapet at the salient angle.

The enemy’s third trench or parallel is generally at such a distance as to touch the exterior side of the glacis opposite the bastions and ravelins.

To determine the height of the angle of the shoulder.

As the distance between the salient angle of the demi-lune and the third parallel or exterior side of the glacis:

To the distance between the angle of the shoulder and the third parallel in the direction of the salient angle of the demi-lune:

So is the height of the glacis before the salient of the demi-lune + 2 feet:

To the height of the angle of the shoulder.

In the former proportion three feet, and in the latter two feet, are added to the height or command of the glacis, that the fire of the body of the place may not injure the men in the covered way. The same is done in every other work.

The command of the faces being determined, that of the flanks is made the same. The command of the curtain is a straight line joining the crest of the angles of the flanks. It may be observed, however, in general, that two or three feet, according to circumstances, are frequently added to the command determined by the preceding rules.

To determine the command of the demi-lune at its gorge, or the extremity of its face on the counterscarpe of the great ditch.

As the distance between the salient angle of the place of arms and the third parallel:

To the distance between the extremity of the demi-lune at its gorge, and the same parallel:

So is the command of the glacis before the place of arms + 3 feet:

To the height of the demi-lune at its gorge.

To determine the command of the salient of the demi-lune.

As the distance from the salient of the covered way to the third parallel:

To the distance between the salient of the demi-lune and the same parallel:

So is the command of the glacis before the salient + three feet:

To the height of the salient of the demi-lune.

When the command of the demi-lune is determined by this rule, that of the enceinte, as formerly mentioned, requires to have two or three feet more than the above rules give. The command of the reduit within the ravelin ought to be three feet.

The preceding methods of determining the profile of a place, will in ordinary cases give nearly the following heights: For the salient angle of the bastion 17 1/2 feet, and the shoulder 21 feet; for the gorge of the demi-lune about 17 1/2 feet, and for the salient angle 14 1/2. The interior side, or command of the glacis, as has been already stated, is 7 1/2 feet above the covered way, and its declivity towards the field ought to be 1 foot in 24. If the declivity be greater, it covers the enemy’s trench or parallel; and if less, the covered way becomes exposed.

The revetment of the rampart ought to be equal in revetment to the crest of the glacis, and at least 25 feet more, above the bottom of the ditch. This gives 18 feet for the depth of the ditch below the covered way. Sometimes the revetment is not carried so high as the crest of the glacis, and the escarpe above is planted with thorns, or defended by palisades. This is called a demi-revetment; but it has the disadvantage of assisting the enemy in the escalade, and therefore ought not to be adopted unless the ditch can be inundated with water. For the same reason, the revetment should not terminate at top, as it often does, with a berme or round way, which serves only to afford the enemy greater facility in fixing their scaling ladders. The thickness of the wall of the revetment should be at least 4 feet at top, and 5 if the height exceed 12 feet. At bottom, the thickness ought to be one-sixth of the height. To strengthen the revetment, counterforts or buttresses of solid masonry, from 3 to 3 1/2 feet thick, are built behind it, at the distance of from 10 to 15 feet between centre and centre, which support a considerable part of the pressure of the rampart. When the ditch is dry, a row of palisades is sometimes constructed in the bottom along the centre.
FORTIFICATION.

When counterguards, lunettes, flches, &c. are used, their command is to be determined by the general rule, that every work must be three or four feet lower than the ground behind it. Detached crown works and horn works are to be considered as separate fortifications, and their profile constructed by the rules laid down for that of the enceinte. The profile of a place is represented in Fig. 4.

The rules laid down above for constructing the profile of a fortification, are applicable only to level ground. When the country is uneven, it becomes a problem of considerable intricacy to determine the heights of the different works. The method now commonly practiced is as follows:

A horizontal plane is supposed to pass through the highest point of the ground within the distance of 2400 feet of the intended enceinte. From this plane, which is called the plane of comparison, vertical lines are drawn to every remarkable point of the place to be fortified, forming as it were a chart of soundings, in which the plane of comparison represents the base or surface of the sea. These vertical lines, as in the case of soundings, are called cotes, their different lengths being marked on the plane. If these lengths differ no more than from two to three feet, the ground may be considered as level, and fortified accordingly. If the inequalities are greater than this, regard must be had to them in determining the relief.

From what has been already said, it may easily be perceived, that the crests of all the parapets, on the same front of a fortification, terminate in a plane more or less inclined to the horizon, as the different works are more or less elevated above one another. In the same manner, the surfaces of all the terre-pleins, and indeed of any other corresponding parts of the works, lie in a plain parallel to the former, and as far distant from it as these parts are lower than the parapets. Such planes, in general, are called planes of defilement; and that which passes through the covered way, the plane of view or of site, because it determines all the others. The plane of view ought to have such a position, that it will pass from four to six feet above the highest point within 2400 feet of the front. As three points are necessary in determining any plane, the three employed in this case are two in the line intended for the covered way, and one on the summit, or rather five to six feet above the summit of the highest ground about the place. If the line joining the two first points be horizontal, the cotes of the plane of view, or the distances of the different points in the plane of view from the plane of observation, may be found by the rules already given for determining the relief of a fortification or level ground. If that line is not horizontal, the angle of its inclination is first to be ascertained, and from that the cotes may be easily computed.

If an eminence running along a front be nearly of an equal height, the front ought to be parallel to it; but if the eminence is higher at one extremity, the front ought to be at a greater distance from the higher part than from the lower.

If a front runs across an eminence, the parts of the front at the bottom on each side are to be covered by salient works on the top of the eminence, and the whole front may then be constructed on one plane of view. If it crosses two eminences with a valley between, it will require two planes of view, always taking care that there be salient works on the eminences, by which the enemy may be obliged to open his trenches at a greater distance. If the place be surrounded by eminences on all sides, each front will require a plane of view for itself.

In our introductory remarks to this article, we took occasion to enumerate some of the leading advantages which a country derives from fortifications in general, and particularly from those on the frontiers. With regard to the position of the latter, it may be observed, that if the country be mountainous or woody, a few fortifications on the most commanding positions will form a sufficient cordon for opposing an invading army. This cordon ought to be either a straight line, or convex towards the enemy, as in this direction it affords greater facility to the different posts in assisting one another. If the country be level and open, it will be necessary to have two or three lines or cordons of fortified places, that the enemy may be forced to encounter at least ten or twelve sieges before he can enter the country in great strength. If a river forms the frontier line, the fortifications are to be placed at the junction of the river with other rivers—on islands, eminences, or any other advantageous position. Care should also be taken to cover the sluices that may be constructed for inundating the country, when that measure is rendered necessary. Fortifications should always be equally distributed according to their strength, so that the weaker places may not be all on one part of the frontier. But the side which chiefly demands the attention of the engineer, is the sea coast, which is always more easily penetrated, and consequently requires the assistance of every advantageous position that can possibly be obtained.

The enceinte of a fortification may be a figure of any different number of sides, from a square upwards, the length forms of the side in each being 1100 feet. All figures, however, are by no means equally advantageous; and therefore it is of considerable importance to determine the comparative merits of each.

The square may be readily fortified, so as, by means The square, the number of ravelins, counterguards, and tenailles, to be equally strong on every side. But the garrison which it is capable of containing is comparatively small; and it is scarcely possible to make it hold out more than from twelve to fifteen days. The same remarks are applicable to the pentagon, neither the one nor the other being fitted for an important position.

The hexagon is superior to either of the former. Its hexagon faces and flanks are sufficiently large; it will admit of other outworks besides ravelins, counterguards, and tenailles, and will contain 4200 infantry and 100 cavalry. It can only be used, however, in situations where assistance can be quickly obtained, as it cannot be made to hold out longer than from twenty-two to thirty days.

The heptagon and octagon will contain a garrison of Heptagon men; and, by the help of outworks and octagon and mines, may be rendered capable of a considerable Heptagon resistance. The defence of the heptagon may extend Octagon from twenty-two to thirty-five days, and that of the octagon from thirty to forty-five.

The enneagon, decaagon, and endecagon, are capable of containing 4000 or 5000 men; and consequently, &c. from so large a garrison, can spare a greater force for the defence of outworks, than a polygon of fewer sides. If, with the outworks, they possess the advantage of inundation, they may be considered as places of the first order. Under these circumstances, they may hold out from forty to sixty days.

Dodeca and polygons of more than twelve sides are Endecagon considered as the strongest of all fortifications. They contain a garrison sufficient to defend not only the places themselves, but also the passages leading to them, as well as smaller forts in the neighbourhood. If all the

In batterdeau canal to and bridge. fortress, camps.

ning run-

ber, &c. de-main, ed cover class enemy should the Citadels, that be called for- ed masonry, for- the eminences, for- days.

It is also to be observed, in comparing these various figures, that the polygons of a smaller number of sides are much more expensive than those of a greater number, if the same advantage in point of strength is to be derived from them; at the same time that a much smaller army is required for besieging the former than the latter. A hexagon may be completely invested with 25,000 men—an octagon by 35,000—but a decagon, or dodecagon, will require 50,000.

Places that require to be defended only from a coup-de-main, such as passes, tops of mountains, harbours, &c. will be sufficiently protected by a fort, or small fortress. Of this kind are the forts near Antwerp, Dunkirk, Brest, Toulon, Dover, and in almost all the colonies in the East and West Indies.

Intrenched camps are works designed for the protection of an army near a fortress, by taking advantage of moors, water, &c. in the neighbourhood. Under this class of works may also be included the forts constructed about a large town to prevent a siege, as well as to cover the magazines in the place from the enemy's fire. If such works are raised about a fortress, they should be sufficiently near, and strong enough to form an intrenchment. If the fortress be on the frontiers, such works are very useful.

Citadels are forts, or large redoubts constructed within fortresses, for the purpose of commanding the town, should the inhabitants prove refractory, and to serve as a retreat to the garrison when the place surrenders. Citadels consist of an earthen rampart and a ditch, but ought always to be stronger than the fortress, that the enemy may not be tempted to attack them first. If possible, the ditch should be filled with water; if not, it must have a revetment. The souterrains of the citadel should be large enough to contain the garrison; and the communications with the town should be such, as they may be destroyed by mines when necessary. The space between the town and the citadel is called the esplanade, and is from 300 to 400 feet wide. In citadels, as well as in all other forts, martello and other towers may be used with considerable advantage.

The form of a fortress depends a good deal on the nature of the ground on which it is constructed. If the ground be quite level, the fronts may be equal in every respect, both in the trace and in the relief. If a river runs through a town, it should pass under the rampart, and be covered with a shell-proof arch. The entrance of these arches are to be shut up with iron doors on the outside; but, if the river be navigable, on the inside. The water of the river is to be used, if possible, for filling the ditches at pleasure; and for this purpose, a bastion de to is to be constructed across the river at its entrance, and along each side, so as to stop the communication between the river and the ditch. By means of sluices in this bastion de to, the water may be thrown into the ditch, and let out by a similar bastion de to at the opposite side, when the river issues from the place. These bastions de to are to be six feet above the usual height of the surface of the water, but never so high as to be seen by the enemy.

If a river runs close by a place, no other work will be necessary on that side, than a single enceinte with a covered way; but if there be a gate towards the river, it will require to be covered with a strong work called a tête-de-pont, or head of a bridge. If a canal be carried from the river through the place, the sluices that form the communication must also be strongly fortified, and the entrance of the canal or river into the place covered with demi-lunes, lunettes, &c. It will be found most advantageous to let the river or canal issue from the place at the curtain.

If a fortress be situated on a hill, the rampart should be constructed so as to enflace the declivity of the hill as much as possible, independent of the outworks. Such fortresses are generally small, but very strong. If the situation of the place be in a moor, or ground any way impassable, it is still more easily fortified, particularly if there be a command of water. A single enceinte with demi-lunes before the gates, will in general be sufficient for such a place; but if there is a more easy access on any side, it is to be covered by stronger works. These outworks ought to have the gorge enclosed by a wall with loop-holes.

When a fortress has a place on one side, and a moor; in a moor height, or impassable marsh on the other, the side most open to attack should be nearly a straight line, while that towards the other may have a considerable degree of curvature. With regard to the works necessary on each side, the observations we have already made will be found useful; though, after all the directions that can be given, a great deal must in every case depend on the skill and experience of the engineer. It may be observed in general, however, that fortifications on unequal eminences, or on eminences and plains, are always disadvantageously placed; but when it is necessary to construct them on such places, the side most open to attack should have as open bastions as possible; and if such sides have eminences in front parallel to them, or nearly so, it will be necessary, in many cases, to occupy these eminences by detached forts and other strong works.

When a place is situated on the sea coast, the side next the sea may be secured against a coup de main, by a single enceinte, or by strong detached works. When the place is at a distance from the sea, but communicates with it by means of a long canal, forts are to be constructed along the canal at convenient distances; these are generally placed at the ends of dams or dikes, and so formed as readily to enflace the canal or its bank. If the forts can be approached by vessels, they ought to be of masonry, and the guns mounted upon them should be 36 pounders. They ought also, in this case, to possess the means of making red hot balls.

SECT. II.

Temporary or Field Fortifications.

Such is a general sketch of the modern system of permanent fortification, or the construction of fortresses that are to be permanently used as places of strength. We shall now proceed to consider the most approved plan of field fortification, or the construction of temporary works for protecting an army, or a detachment in the field.

As field works are constructed of the same materials, General use and intended for a time to serve the same purpose as fortresses, many of the general principles laid down above, in the construction of the latter, are equally applicable to the former. The strength of each consists of an earthen mound, with a ditch before it, and the only difference, therefore, between them, is in the form, size, and number of works. The first object in field fortification is to give the work such a form as will render it most capacious at a given expense. The flanking defence should be as much as possible employed, and the flanked parts within the range of musket shot, that is
FORTIFICATION.

490 or 500 feet. The salient angles are always to be stronger, and dead angles, or points, that cannot be seen from any other part of the work, as much as possible avoided. To render the faces more nearly parallel to the field, the salient angle should be very obtuse, and its defence will be considerably improved, if, instead of forming an angular point, it be truncated, rounded, or serrated. These different forms are represented in Fig. 5. A, B, C. Salients like C, where the faces consist of a suite of small salient angles, are useful in removing all unflanked angles; but the sides, forming each of the small salients, ought never to exceed two feet; when they are more than this, they either weaken the parapet, or they render it necessary to increase its thickness, which both adds to the expense, and encroaches on the room within. Perhaps, upon the whole, the best form of a salient is the circular represented by B. With these general remarks, we shall now proceed to enumerate the principal works employed in field fortification.

The redan is a work consisting of two faces, like a demi-lune, sometimes also having flanks, in which case it is called a pince. As the redan has an open gorge, it is easily taken in rear, and is therefore never used but to cover a road, dyke, village, castle, or other work.

The redoubt is an isolated work, and of course forming a complete enceinte. It is generally triangular, square, or circular, and sometimes also a polygon. The triangular form is seldom used indeed, its angles being too acute, and the space within too small. The circular redoubt encloses a large space, but is difficult to construct, and cannot be well flanked. The square, or pentagonal form, is therefore most commonly used.

As a redoubt is liable to be attacked on every side, its size ought to be so proportioned to the number of the garrison, that it may be defended on all sides at once. To be sufficiently defended, a side will require a man to every yard, and three ranks of men. The first rank fires, the second loads, and the third acts as a body of reserve.

The weak defence of such works generally arises from the bad disposition of the men who are to defend them, and therefore great care is necessary in accommodating the work to the number of the garrison. A redoubt, whose side is about 12 yards in length, will inclose 36 square yards, but will contain men enough only for one rank along the parapet, and is besides much exposed to the destructive effects of stone balls and shells. This is, therefore, the smallest redoubt that ought ever to be constructed; if the side be 14 to 16 yards, the space within will be 60 to 80 square yards, and will contain men sufficient for one rank and a reserve. A side of 18 to 20 yards will afford room for 144 men, being enough for two ranks, and, in general, the more the sides are increased in length, the greater proportion will be the room afforded for the garrison.

This is to be understood, however, only of isolated works, as those to which succour can be readily afforded, do not require to be increased at this rate. If the side of the redoubt exceed 30 yards, there will be accommodation within for 500 men, of which 384 will be sufficient for a complete defence. In this case, therefore, the redoubt may be constructed with flanks; and, if guns are to be planted upon it, it may also have outworks. The general rule for determining the fire lines of redoubts, is to allow three men to eight square yards of interior room, if the garrison exceeds 50 men; but, if less, one man to two square yards. Redoubts are of great use in preserving a communication with advanced posts, and defending a defile, height, passage of a river, a frith, or even the wings of an army; but they are also very defective in some respects. They have unflankéd angles, and a dead angle all round the parapet. The first may be remedied by placing them in such a situation that their salients cannot be assaulted.

A fort, or field-fort, resembles a redoubt, but is larger, and has a greater variety of forms. It is called a fort when isolated, and a tête when the gorge is placed upon a river, defile, &c. When forts are not irregular, which is, however, in many cases, the most advantageous form, they are either star forts or bastion forts. Star forts, or forts à teneur, are such as form a regular suite of salient and re-entering angles. They may be considered as polygons, whose sides are broken so as to form the re-entering angles. If possible, the salient angles should never be less than 60 degrees, and the nearer they approach to 90 the better, as a rectangular defence is always the best. The brises, or faces, forming the re-entering angle, should not be less than 50 feet, nor more than 100. If they are longer than this, they require a numerous garrison to defend them, and it would therefore be better, in such cases, to construct a small fortress, especially if guns are to be used.

Star forts are seldom constructed either in the triangular or square form, a redoubt being almost always preferable to either. In a triangle there can be no brises, in a square their angles are 150 degrees. A pentagon is somewhat superior to both, the defence of its salient angles being better, and the angles of the brise 132 degrees. The hexagon is still better than the pentagon, though its salients are by no means well defended. The heptagon has salient angles of 126 degrees, and those of the brises 112. This form might therefore be used with considerable advantage; were the construction not so difficult; the most convenient, however, as well as the most advantageous polygon for works of this kind, is the octagon. The construction is made either upon the interior polygon, by placing equilateral triangles on its sides, or on the exterior side, by means of the perpendiculars from the salient and re-entering angles.

Bastion forts have frequently been proposed; but in general they are inferior to star forts. The triangular half-bastion is peculiarly defective. They are difficult to construct—the salients are too acute and ill-defended—the faces of the demi-lunes are without any cover, and the interior surface is too small. The square half-bastion is little better than the triangular, but it incloses a larger space. When the bastions are full, the work may sometimes be very advantageous, and the construction is the same as in permanent fortification.

In bastion forts the sides should not be less than 100, nor more than 200 yards, that the flanked parts may be within musket shot. Perhaps 150 yards is a good medium. The best form of the curtain is to break it twice, by which a very advantageous fire is obtained.

The principal things to be considered in field fortification are the nature of the ground, and the soil to be used, the attack that is likely to be made, the relative importance of the place, and the number of the garrison.

When the place is to be defended against small arms, the talus only, the talus may be as steep as possible, from the summit of the parapet to the bottom of the ditch; the base being equal to the height. If guns are to be used, the slope should be greater, to make a better defence. The base, in this case, may be one-third of the height,
If a work is situated on ground where it is liable to be enfiladed, it must have traverses in the interior. The thickness of these traverses depends on the attack which they may have to sustain. If this consist of small arms only, two feet will be sufficient; but they will require 6 to 9 feet, and, in some cases, 10 to 11 feet, to hold out against field pieces. The talus must be as steep as possible, that they may occupy little room, and to preserve the communication they ought to have passages through them. In every work, indeed, there should be openings from 4 to 5 feet, or from 8 to 9, according to the size of the work, to keep up a free passage between the different parts. The talus of these entrances must be as steep as possible, and they are to be shut up with chevaux de-frises, large branches, and other barricades. They ought also to be covered by a traverse behind them, 6 feet longer than their width, and from 3 to 9 feet in thickness. This traverse has a balustrade, from which the soldiers can fire on the enemy, in approaching it. Before these entrances, it is usual to construct a bridge, consisting of boards laid on scaffolds in such a manner as to be readily removed or destroyed when necessary. This bridge is about 3 feet wide in small works, and 9 to 10 in works whose guns are mounted. The gorge of a work is always to be inclosed, at least by parapetos, to prevent a surprise.

If a work is to be occupied for any considerable Corps de length of time, it should be furnished with a corps de garde. In small works this may consist of huts covered with branches; but in larger places it should be of timber, and have if possible a shell proof covering. The exterior parts of a fortification may be increased and strengthened either by active or passive works of defence. A covered way, however, is in general of little use in field fortification. It is very expensive, it adds 3 to 4 feet to the height of the profile, weakens the rest of the parapet, requires a deeper ditch, and can be defended only by a large garrison, which, however, generally retires before the assault is made, and creates confusion within the place. When the work is pretty large, a covered way may be used, and when the crest of its parapet ought to be 4 feet above the horizon; and if it be dug out behind the glacis, the latter will require a balustrade. The width of such a covered way is nine feet. Traverses are seldom used in the re-entering angles of the covered way in field works. If they are used it is to cover an entrance, and are constructed in the same way as places of arms in permanent fortification. Such traverses, however, require a great command. The parapet must be at least 11 to 12 feet. A simple glacis therefore, is perhaps better, except in very large works. A second glacis, without any covered way, is of great use in field works. Where it is used, the parapet will require only from 8 to 9 feet of command, and the obstructions that may be laid in the enemy's way, are better concealed. Such a glacis is also of great advantage where small works, as fleches, are used, and may be successfully employed in producing little imitations, particularly if ditches are made in it at short intervals that cannot easily be passed. It is always of the greatest importance, indeed, to have the fossé full of water.

The fossé before the parapet, in field fortification, is generally not very deep, but ought never to be less than 6 feet, and always 12 if possible. The talus of the fossé may be steeper than that of the parapet, as the earth of the former possesses its natural adhesion. Of course the base of such slopes is very small compared to their height.

**Travesses.**

If the earth is heavy, one-half if lighter; and two-thirds, if it be sandy or stony. To keep the talus from falling down, gazons are used whenever they can be conveniently obtained. Revetments of various other kinds have also been used, as fascines, saucissons, hurdles, trees, boards, &c., but no method of constructing the talus appears so easy or so advantageous as that already described, especially if it has a row of trees on the front, standing seven or eight feet above the ground. Sometimes it may be useful to interrupt the talus by a berme, so as to take the pressure of the parapet as much as possible off the counterscarp. Care must be taken, however, that this berme be at least 5 feet 6 inches below the exterior summit of the parapet, lest the besieger take advantage of it to fire over upon the garrison. Parapetos and chevaux de-frises, or beams stuck full of pins, &c. are useful on the berme, only when it is covered from the enemy's fire. The interior slope of the parapet must be as little as possible, that the soldiers may approach close to it. From 10 to 16 inches of a base will be enough, and it ought to be lined with fascines, boards, or gazons.

The balustrade behind the parapet, in a single work, should be from two feet to two feet six inches broad; but if the work has a curtain resistance, it ought to be 4 feet in breadth, to afford a ready communication. It should also be from 4 feet to 4 feet 3 inches lower than the parapet, and have a slope or stairs of fascines towards the interior by which it may be ascended.

All these works, when they are intended for a short resistance, consist only of a parapet; but when they are larger, and intended to hold out for a considerable time, they have generally a small rampart, for the convenience of the artillery.

The upper slope or plonge of the parapet ought to be directed to the upper part of the counterscarp; or if it has a great command of the surrounding country, it may be directed somewhat higher, as the slope should never be more than two to three inches in the foot, lest the upper part of the parapet should be too much weakened. This is, indeed, double of what is allowed in permanent fortification. If the plonge cannot be directed to the crest of the counterscarp, it will be proper to construct a glacis, having the same slope as the plonge of the parapet. It is to be particularly observed, however, that if a place can be cannonaded by the enemy, the slope is to be reduced as much as possible.

The thickness of a parapet depends on the purpose for which it is intended, and the ordnance that may be brought against it. If it is only a temporary place of security, till reinforcements come up, two to four feet in thickness will be sufficient, as it will, in all probability, be attacked by small arms alone. But if great guns are likely to be employed by the enemy, or if the work is to continue for any considerable time, the parapet ought to be at least 10 feet. A four pounder ball enters about 4 feet, an eight pounder 6 feet, and a two pounder about 8 feet in common earth, such as is generally used in constructing fortifications. If therefore a heavy cannonade be expected, the parapet will require to be 12 feet, or perhaps in some cases more.

The fossé before the parapet, in field fortification, is generally not very deep, but ought never to be less than 6 feet, and always 12 if possible. The talus of the fossé may be steeper than that of the parapet, as the earth of the former possesses its natural adhesion. Of course the base of such slopes is very small compared to their height.
be arranged in three rows in echiquier, like the black squares in a chess-board.

Palisades are obstructions that may be used at all times, but their advantage depends principally on the manner in which they are employed. They are constructed in different parts of the fossé, and placed in various positions, according to the expected attack, and the kind of defence which the ditch possesses. Care must be taken, however, to place them without reach of the enemy's large guns. If trappes de loupes are before the fossé, the palisades ought to be behind it.

Another method of strengthening a place, or rather of obstructing the enemy, is to plant large branches of trees on the upper escarp, on the berme, or behind the glacis. The last is perhaps the best position, as they are defended from the enemy's fire. Chevaux de frises may be substituted for branches, but they are more difficult to be procured.

Besides these, various other obstructions may be employed to prevent or retard the enemy's approach; as stakes driven into the ground for a considerable space together, heres fixed in an inclined position, caltraps, &c. These, of course, are to be adopted or not, as circumstances may require. In some cases they may be of little use.

Fougasses. In field fortification, fougasses, or small mines, are frequently of great advantage, provided they be carefully attended to, and fired at the proper moment. The fournaux of these mines are laid twenty or thirty paces before the counterscarp, and the sawdust, or long thin bag of powder for firing them, is conveyed by means of an auger, or wooden trunk. Mines can only be useful when the powder can be kept dry for some time. Laterally, these fougasses are too expensive, and of less use than smaller ones. The best position for them is before the salient, as there the attack is more likely to be made.

The fossé of a fleche is defended at its gorge by caponniers, or by palisades three to four inches thick, having, at the distance of every 24 feet, an opening like a loop hole, or a low palisade, which answers the same purpose. The entrance to the work may be concealed from the enemy by the palisade, on one side projecting before that on the other. Such a defence, however, can only be used where a work cannot be attacked in its gorge. A stronger defence of the same kind, for the gorge of a fossé, is by means of two rows of palisades, fastened at top by cross rafters, on which are placed fascines, and the whole covered with earth. Montalember has proposed to construct these with a salient angle, and, that they may be less exposed, to place the loop holes about two feet above the bottom of the fossé, but lower than the glacis. Such caponniers have a subterraneous communication with the interior, by a passage lined with poles and boards, and are surrounded by an abatis, or by trappes de loupes, to prevent the enemy from approaching them. Similar caponniers are placed in the salient angle of the counterscarp, ten feet distant from the ditch, which is there enlarged to twelve feet in width towards the field, and lined with poles, boards, &c. The loop holes of these caponniers are formed so as to enflame the glacis, and the gorge towards the ditch is shut by strong palisades. They are also surrounded, like the others, with trappes de loupes, or an abatis. It may be observed of all these caponniers, however, that they cannot be made to hold out long against a cannonade, and are therefore useful only when that is not to be expected.

In large forts, it is sometimes of advantage to have a reduit to which the garrison may retire, and which, of course, may be large enough to contain them, till such time as assistance, or favourable terms of capitulation, can be procured, in case the fort should be taken. If the reduit is constructed of earth, it will require no greater profile, than merely to command the work before it. If it be made of timber, it is to have loop-holes, by which the soldiers may fire on the enemy, without being exposed to his fire; and it should be so constructed as to enflame every part of the fort. The cover must, if possible, be shell-proof.

Similar to this is the work proposed by C. Muller, consisting of a reduit, with four small bastions at its salient angles, the diagonals forming a sort of caponniers of wood-work. In the middle, where these caponniers meet, this wood-work has two stories, with loop-holes in the walls. All such works, however, being of wood, are easily destroyed.

The most advantageous kind of reduits are block-houses. These have walls formed of rafters, from one to three feet thick; and roofs, consisting of two layers of the same, overlaid with fascines, and covered with earth, so as to be shell-proof. Such houses may even supply the place of a fort, and are particularly useful in winter. The access is by a ladder to the top, or by a side door, which is sufficiently defended by palisades, and also by abattis or trappes de loupes around it.

Traverses are useful in the interior defence of a work, if they are so constructed and distributed as not be exposed to an attack behind, nor liable to be enflamed by the enemy.

A work may be defended either by cannon or small arms. The advantageous use of the former depends on the tracing of the work, and the number to be employed. It is to be observed, however, that the guns are always to be placed so as to enflame all the avenues to the place, and enflame the works before them. The best situation for cannon appears to be the flanks and the salient angles; and that they may the more readily be brought to bear on the enemy, in whatever way he approaches, they should be fired there en barbette; that is, on the parapet, without the assistance of embrasures.

Sometimes, however, guns will be more advantageously placed behind the embrasures, viz. to defend a defile, or any narrow passage; and in this case it is proper to cover the artillerymen, in order to protect them from the enemy's tirailleurs, who always approach very near to the work, being covered by the ground, and thus make great havoc before they come within reach of the fire of the small arms. The artillerymen who serve guns mounted en barbette in salient angles, are very much exposed to danger; for, if the cannon can only fire a single shot, while the enemy's tirailleurs can molest it from all sides; and, therefore, artillery alone will not always prevent the enemy from taking a work. Artillery should therefore never be placed in works where the enemy can approach with ease, as in such cases it will have little or no effect. From this it will be evident, that wherever cannon are employed, it will be necessary that they should not be too much exposed, as they can only be efficacious in such places as present great difficulty to the enemy in his approach.

The fire of small arms should defend and enflame every part before a work, and be directed in such a manner, that the enemy may everywhere receive with the best effect; and care must also be taken that it assist the fire of the great guns. The flanks are also
The most proper places for the small arms; but if it
being necessary likewise to defend each part of the para-
pet, and to receive the enemy with a front fire, it will be
requisite to give the small arms a place all round a
parapet, but particularly to place the most numerous
party of them at the flanks. To increase the defence
of the salient angles, the serrated form of the faces is
the most advantageous; but the faces of the small sal-
liants should never be larger than for two men, or at
most for three, one of which is to be placed in its sa-
liant angle.

The relief which, in permanent fortification, is the
most difficult to determine, depends, in field fortifica-
tion, upon particular rules. In general, the height of
the work differs according to its size and situation, and
often depends wholly upon the opinion of the engi-
nier; but there is a minimum of height, below which it
never should be: That minimum is 4 feet 6 inches;
and even this only for such works as merely serve to
cover men from the fire of small arms for a short time;
as, for instance, an outpost. No parapet should, how-
ever, if possible, be less than 4 feet high, if intended
in any degree to command the field it; and to
cover the men completely to any distance behind, it
will require to be 7 feet 6 inches. At this height, how-
ever, the soldier sees his enemy under a smaller angle,
which renders his fire more nearly vertical; a parapet,
therefore, should never, if possible, be higher. If the
height be from nine to twelve feet, this defect increases
considerably; and if flanks are constructed, they have a
large dead angle before them, both of which are always,
if possible, to be avoided. But, on the other hand,
a height of twelve feet secures the interior part of a work
completely from the enemy's fire, and has, in this re-
spect, great advantages. A strict attention therefore
to circumstances, added to a sound judgment, must de-
termine the most advantageous relief for any work.

The covered-way of a field fortification should have a
command of at least 4 feet 6 inches above the ground;
and the terre pleine should be two feet below the latter,
or 6 feet 6 inches below the crest of the covered way.
This may be increased to 4 feet, and even to 7 feet 6 inches, if it is to be made the crest of the parapet
should always have five to six feet command over the
covered-way, and the crest of its glacis; there-
fore, such covered-ways will not be of any use where
the parapet cannot be at least 10 feet high. A simple
glacis round a field-work should never have less than
six feet command below the parapet, that the enemy
may not fire from its crest with the same advantages
into the work, as its garrison can at him. If, however,
there are places of arms in its re-entering angles, then
it is to have the same command as a covered-way, and
also the parapet as much above it.

An avant-glacis is to have at least five feet less com-
mand than the covered way, but must always be made
so high as to cover the objects behind it. If it is si-
tuated only before a simple glacis, the parapet behind
it should have at least six feet command over it.

The plunge or slope of the upper part of the parapet,
should be in the same plane with the glacis, the covered
way, or the avant glacis. At all events, this plane should
never pass at a greater height above the crest of the
glacis than two feet. The same is to be observed if
the earth for an advanced glacis is dug out behind it;
and in this case, no part of the ground behind the ad-
vanced glacis should be more than two feet below a
plane passing through the crests of the covered way
and the parapet. The command of outworks is also
the same as of the glacis of the covered way, if not
more than 200 yards distant from the principal work.
If, however, the principal work has a covered way,
this is to have a command of five feet above it; and
consequently the parapet must have from eleven to
twelve feet command above the field. Should the prin-
cipal work be an outwork, then that which covers it
must have a command of at least twelve feet above the
covered way and its glacis before it. The command of
field fortifications varies therefore considerably from
that of permanent fortification; it being in the former
from five to six, and in the latter only two to four feet.
The reason of this is, that the enemy can attack the
latter without being covered, but he can only approach
the former while covered by a parapet, which forces
him always to be at least seven feet lower than the
crest of the work he attacks. The method laid down
for works in permanent fortification, to determine their
relief, being too artificial, and requiring too much time,
is not applicable in field fortifications, and here, there-
fore, a more simple method is requisite for determining
this relief. But it will frequently be found impossible
to give such a relief as may have been determined
upon, and in this case a more advantageous one is
to be chosen, and preferred to a great command. By
this means, field works can be made much stronger
than by a defilement artificially chosen, as in permanent
fortification, and which is perhaps still more difficult to
be executed than that given by the above rules.

Works which are open in the gorge, or which can-
not be attacked from behind, must be at least 300 yards
distant from any eminence which commands it, if only
small arms are to be feared; but if cannon are employ-
ed, it will be necessary that the distance should be at
least 900 yards.

The defilement of a work, which is open in its gorge,
Defilement, if it be necessary to place it nearer to a mountain than
of such 900 yards, is determined as follows:—Poles four feet
works—six inches in length are erected on the highest visible
Against small emi-
sunmits of the mountain. The points which it is re-
required to cover by the intended work, are then mar-
ed, and poles erected at them of such a height that
their tops shall just be within the command of the para-
pet. These poles being united at top by a cord, the
salient and re-entering angles of the work are deter-
mined, and poles erected at each, of such a length that
their tops shall be in a line with the cord and the poles
on the mountain. The height of these last poles will
give the height of a work necessary to have a given
command over a given place near an eminence.

After determining the defilement of the parapet in this
manner, the tops of the poles along the line of fire of the
parapet are united by a cord, and wherever the line of
this cord is below the plane of defilement, it is ele-
vated by means of poles.

In the same manner the defilement for works to re-
sist artillery is determined, if the heights are not above

a free communication, it being necessary that no part of the defence of the works be obstructed. The traverse is always to be determined at first, where two planes of defilement are necessary; but, where all the works can be laid down according to one plane of defilement, the parapets are determined, and then, at proper distances from them, the place for the traverse is chosen, and afterwards constructed from this point to the salient angle of the work.

A work may have only one re-entering or salient angle, or it may have several such; the plane of defilement, however, remains always the same, as described above; but care is, in this case, to be taken not to injure the flanking defence too much, and also not to make the dead angles too large. Several planes of defilement will, in this case, frequently be necessary. Inclosed works commonly require an enormous height to cover the men in them; and as this can seldom be allowed in field fortifications, traverses are generally preferred for this purpose.

In this case, the position of the traverses is directed in such a manner as to take up the smallest room, and at the same time to cover the greatest space. The nearer the traverse is towards the commanding height, the more space it covers, and the smaller the relief may be, but the traverses are the higher. Their defilement is made out in a similar manner to that above described; but care is to be taken in placing them so as not to block up the communication. The only case where the traverses will not be wanting, is when the ground on which the work is constructed slopes, and when by this its interior is covered. The traverses should always be nearly parallel to the heights as possible; and therefore, if a work is commanded from several heights, the traverses will cross each other.

The most difficult case is, when a work is situated in a tunnel, or every where surrounded with commanding heights. In this case a block-house, or a corps de garde, is to be constructed in the middle of the work, which is secured from balls, and which, at the same time, serves as a traverse for the men who defend the work, or to secure its interior parts.

Lines or works connected with each other, and forming intrenchments, should always be strong enough to resist guns; and therefore, if they are not above 900 paces distant from the height, their defilement is to be arranged accordingly. If such heights, therefore, occur, they are either to be occupied, or the position is to be somewhat altered, which is in general easily done, as the engineer will not be so much restricted on any given place as in permanent fortifications. However, in all cases where heights occur, and where the lines always remain commanded, advanced works on these heights are of the greatest use.

Should a valley between two heights require to be fortified, strong advanced works will be advantageous. If, however, the valley is very narrow, the line may have very salient parts on the heights, and be frequently broken; but if these lines do not cover the places behind them sufficiently, then traverses must be chosen, and constructed at such places as may be deemed necessary.

The next important point to be considered, is the application of the works to the field. Small works and single posts may be established by officers of infantry, but large and composed works only are to be directed by engineers.

An army may be in want of fortifications in different cases, viz. if it has to cover a large part of a country; if it has to act at another place, while a part of the frontier is to be well covered; if an army goes to a distance from its frontiers in an open country; if it fears an attack from a superior enemy; if it is inclined to make its retreat in sight of a superior enemy; and if an army besieges a fortress.

To cover a frontier, every obstacle that can be procured, as well as every thing that tends to strengthen a line, ought to be employed. The use of fortified lines has by some been recommended, by others it has been considered as unnecessary. The former, however, appear to be right, in as far as the lines serve to protect and to inclose a country.

Such lines as serve to protect a frontier, extend from two parts, where the enemy cannot pass, or where the line can be appraised, and for their better support, they generally have fortresses along them at certain intervals. Towns, rivers, rivulets, habitations, and all other impediments to obstruct the enemy's advancing, should in such cases be made use of.

To protect whole parts of a frontier, fortified places, or rather fortresses, are the most effectual; but where there are none, large towns, and other places commanding the roads, the rivers, and the valleys, by which an enemy may approach, should be fortified in such a manner as may enable them to sustain a slight attack, and to obstruct the enemy's advancing for a few days. In this respect, strong places, consisting of fortified and frontier posts, are of the greatest advantage, if properly chosen and well constructed. They are generally surrounded with strong works, which defend each other, and also all the avenues or passages and roads, as well as the ground leading towards them. In this respect, inundations, abatis, crenelled walls, houses fitted up like block-houses, and all other possible means of defence, should be used. Sometimes houses must be pulled down, and outworks constructed, if by these means a town can be rendered stronger and less open to attack.

Intrenched camps near the frontiers differ very much from permanent camps and frontier posts, having no habitations for the troops in them, and being only intended to serve for a short time. They generally consist of works constructed like field fortifications; but, that they may be tenable as long as possible, they ought to be situated behind such places or parts of the ground as do not allow the enemy to approach.

Têtes-de-ponts, or bridge-heads, are smaller or larger fortifications, raised before a bridge in order to cover it. Small têtes-de-ponts consist only of a single rechin, as ABC, Fig. 6, the sides of which are favourably flank ed by two traverses D and E. Such têtes-de-ponts are always to be constructed there, that the enemy may not attack them; that the bridge which they cover may not be destroyed by him; and that, while attacking, he may be taken in flank. These works frequently require a considerable space, either to contain divisions of an army retreating by them, or to cover a large space of the river or its banks. Large têtes-de-ponts are represented in Fig. 7, and still larger in Fig. 8. Têtes-de-ponts must always be well flanked towards the enemy by the other parts of the works, and ought also to have a proper flanking fire of their own. The entrances to them should not be too small, to retard the movements of the troops; but they should be well defended, so as to deter the enemy from approaching them.

An army which is weaker than that of its enemy, must sometimes either maintain its position, or secure
FORTIFICATION.

its movements by the aid of fortifications; and, in this case, whole lines, or connecting works, are to be constructed, in which advantage is always to be taken of the natural impediments offered by the ground, so as to strengthen these works as much as circumstances will permit.

For the intrenchments of armies at present, unconnected lines or fortifications are always preferred; but those which are connected, and which form whole lines, are also of use, where any place is to be covered by a connected line; and, in this case, it is more advantageous than separated works. The latter possess these advantages, however, that they allow the troops free movements; they do not require so many men for their defence; they cover the most essential points, and are constructed at less expense. Besides this, two lines, or even three, may be formed of them, and then they allow a stronger defence than connected lines. The figure to be adopted in constructing lines, is that which admits most readily the use of all kinds of fire-arms. Different engineers have proposed different figures; but what appears to us the most advantageous, is that represented in Fig. 9.

Detached works possess in many cases, as we have already said, great advantages over connected lines, and are in modern times generally preferred. Where a part of a country, however, has been completely enclosed by connected lines, they are, besides having a good profile, made as strong by the impediments of the ground as circumstances will permit. Of detached works, three lines of redoubts are the most advantageous, as they are inclosed, and may be placed in such a manner that they defend each other as strongly as if they had flanks. Each of these redoubts is by itself a strong work; but, when supported by the four neighbouring ones, it can never be taken but by attacking all the others. In such redoubts there should always be a considerable number of cavalry ready to attack the enemy whenever they are thrown into the least confusion.

Fleches applied to this purpose can be taken in rear, if they are not shut; and, even in this case, their garrisons are more exposed, and the enemy may always attack them from behind. It is the same with bastions, though these certainly have a stronger and better defence than fleches, and consequently are preferable. However, their gorges should always be shut, that they may not be taken in rear. The spaces among the detached works are, if possible, made impracticable, and only a few large passages are left open, through which the troops may with ease advance upon the enemy. The first line of such detached works is always to be the strongest, though the great guns should be placed in the second and third lines, that the enemy, after taking the first, may not get the advantage of them in attacking the other lines.

Should detached works be used in a mountainous country, they ought always to occupy the most command ing points; but, at the same time, they should be so situated as to command a pass, and envelope the slope of the mountain.

Should it happen that a small pass is to be defended against an attack of the enemy, it is to be prepared, and, if possible, strengthened by fortifying it. A single house, when it has no stone walls, may be fortified in the following manner: The walls may be strengthened by boards in the inside, or by rafters applied as in blockhouses, or, if these are wanting, by making a ditch round it, and using the earth to strengthen the wall. The doors and windows are fortified with boards, and barricaded. Loop-holes are every where made, but in such a direction that the enemy cannot reach them with his firelocks, so as to fire into the inside of the house. If there is no ditch round it, other impediments are to be made use of, to hinder the enemy from approaching close to the wall. The roof is broken down, and all combustible matter covered with earth and rubbish, to defend the house from an attack from above, which might otherwise be executed by ladders.

In a stone house, the walls will generally be strong enough, or, if not, they are to be prepared as above. The same is also to be observed respecting the windows and the roof; and, if possible, it is to be made shell proof from above. The doors are either barricaded, or defended by a tambour constructed before them, to have a flanking fire.

A church-yard, a farm, or an estate, is fortified in a similar manner; but, if surrounded by a wall, either yard, &c., loop-holes are made through it, or, if too high, a kind of scaffolds, called echafaudages, are to be erected, serving for the soldiers to stand upon while firing. The church, or the building on an estate, are then generally used as a corps de garde, and made shell proof, by breaking down the roof and the uppermost story, and using it to cover the building. The doors, and particularly the corners of the walls round such a place, are generally covered by tambours; but, if time permits, caponiers, and other impediments to the advancing of the enemy, are made use of. The street, and roads leading towards them, are generally made impracticable by old or broken carts, harrows, boards with nails, wheels, &c. All the houses in the neighbourhood, which may be advantageous for the enemy, or which may favour or cover his approach, are levelled, and the rubbish of them used to strengthen the walls. The trees, near such a place, if large, are hewed down or sawed off; that even not a single rifleman may approach covered by any of these parts.

A small, or country town, if surrounded by a wall, is of a small fortification in a similar manner; but echafaudages are generally used behind its walls, and, if possible, two rows of soldiers are employed, one firing through loop-holes, and the other over the walls.

Guns are placed wherever their fire is of the best effect. The gates are barricaded, and covered by impediments which hinder the enemy from advancing there to attack them; besides this, they are covered by traverses, and a flanking fire is established before them, if possible. Only such parts of the gates as are essentially necessary to be open for the communication are not barricaded, but strongly defended. Every thing is to be done that may render the interior communication better and more easy, by means of sufficient passages; but, on the contrary, every means is to be used for obstructing the enemy's advance.
PART II. ON THE ATTACK AND DEFENCE OF FORTIFIED PLACES.

WE come now to the Second Part of Fortification, viz., the attack and defence of fortified places, and shall consider this part of our subject, like the former, under two heads, Permanent and Field Fortifications.

SECT. I.

Attack and Defence of Fortresses.

In former times, there were six different methods of attacking and defending a fortress, viz. 1st. By artifice. 2d. By a surprise, executed either by a secret understandIng between the parties, the stupidity of the garrison, or by masked soldiers. 3d. By force; as the escaleade, the attack demible, or the attack d'emboute. 4th. By inclining the fortress all round with soldiers, in order to take it by a greater force. 5th. By famine; and 6th, By the attack in form, or a regular attack. In modern times, however, a place is generally attacked by the following methods: 1st. By surprise; 2d, By an open attack or escaleade; 3d, By starving it out; and 4th. The regular attack, or strong bombardment. Of these different methods, circumstances must determine which is to be preferred in any given case. Sometimes, however, a fortress may be attacked in one way, which it will be found necessary afterwards to change; and, therefore, it is not always known by what kind of attack a fortress will surrender the soonest. There are numerous instances on record of a place holding out a long time against one method of attack, and surrendering as soon as that method was changed. The surprise of a fortress ought never to be undertaken till the besiegers have gained a considerable acquaintance with the works of the garrison, and even a knowledge of the inhabitants. This may be procured by spies, deserters, or some other source of secret information. The particulars that are peculiarly necessary to be known, in order to render a surprise successful, are the depth and breadth of the fosses, the revetements of the ramparts, talents and disposition of the commander, the degree of confidence which the garrison reposes in him,—how the fortress is watched,—where it is neglected, and the general disposition of the garrison.

By surprise. The most advantageous period for surprising a fortress is in winter, during the long nights; and the best time of the night for effecting it is from two to three hours before daylight. The order for such a surprise is to be given, and the preparations are to be made, as secretly as possible, to prevent the enemy from obtaining any knowledge of it. The march of the troops to execute a surprise ought to be secret, that it may not raise any suspicion; and it must be so calculated, that they may reach their respective places at the proper moment. In proportion to the dispatch and secrecy with which such a march is executed, will be the probability that such surprise will not be discovered; and therefore a sufficient number of people to serve as guides should be ready, that nothing may be wanted, nor any detachment retarded in its operations from unforeseen accidents.

If a secret understanding with any of the garrison or the inhabitants can be procured, it will always be very advantageous: but still it is far superior to gain a secret entrance into the place. It is impossible to lay down general rules for this part of the subject; nor is it necessary, as accident, and the circumstances of the moment, will instantly point out to the experienced commander the most proper mode. It may probably happen, that one part of the town is not well watched; and in this case soldiers may enter there, attack the guard of a gate, and open it for a small party, that has been previously brought close to it. When this party enters, it is to be followed directly by a larger force. Another method of penetrating a town is by approaching secretly to the gate, and opening it by a petard; but this is hardly possible in our times, fortresses being generally so well watched, that it is impossible to approach their gates without being discovered.

The gate of a town may sometimes be entered by masked soldiers, or soldiers who are habited in regimentals like those of the enemy, and who, under some pretence or other, attempt to be let in by night. A similar ruse de guerre might be practised, if the gates were opened too early in the morning. Masked soldiers might also enter a fortress as farmers: and as soon as a sufficient number of them have penetrated, they might attack the guard, and keep one gate in their possession until reinforcements arrive. Soldiers, under the pretence of being deserters, may also sometimes get possession of a gate. A secret understanding with some person in the fortress may essentially contribute to its surrender; and also the sending into the place, unknown to the besieged, a small party of soldiers, who, at an appointed time, are to let in a larger force. Perhaps an officer of the garrison may favour an attack, and thus a strong detachment will easily become master of a gate.

The soldiers who, after the surprise has succeeded, are to be employed in conquering the town, must have already received their orders where to march, and what service they have to perform. Detachments are to be sent directly to occupy all guards and guard-houses, as also all the places of rendezvous, the caserns, the magazines, and all the gates in particular, so as not to allow the enemy to collect any where, or to approach such places. The commandant and all the chief officers are to be made prisoners as soon as possible, and every thing done that can contribute to create confusion among the enemy.

On the instant that a surprise has succeeded, all the guards are taken by the assailants, and all such parts of the works as have been destroyed, or want repair, are immediately to be put into a state of defence. If, however, a surprise does not succeed, then the retreat is to be ordered, and to be executed with as much regularity as possible; and even in case of success, no soldier is to be allowed to quit his rank and file until all the fortress is completely in their power.

The open attack of a fortress, or the attack by an open attack, is, in some respect, similar to a surprise, and an intended surprise is often changed to an open attack. An open attack can only be executed if the fosse of a fortress is easily passed, or if the water in it is not deeper than from four to five feet; if the revetements are not more than twelve feet above the bottom of the fosse, and if the garrison is not always on the alert, so as to direct the fire of guns mounted on the flanks against the assailants. Should there be no revetment or stone to obstruct an escaleade, other impediments may easily be cut off. Thorns, however, and bushes, are difficult to remove, and require a considerable time, if they are planted.
very thick. Ladders used to effect the escalade are to be constructed for the purpose, and should always be of such a length as may be necessary to mount to the top of the revetment. If it be found requisite to use very long ladders, two or more short ones, joined together, will answer the purpose, and will also be more easily taken from one place to another.

Various opinions have been entertained with regard to the best construction of these ladders; but, after all, a simple ladder of wood appears to be the most convenient, as being the lightest. The number of the ladders depends upon circumstances; one for every five men appears to be a very fair proportion.

In attempting an escalade, it will always be of the greatest advantage, if the garrison can be taken by surprise, and therefore all preparations are to be made in the most secret manner. The same secrecy is also to be observed with respect to the movements of the troops, and in carrying the escalade itself into effect. When all the necessary preparations have been made, and the attack is to be undertaken, the troops assemble, and march secretly to the covered way. Having penetrated this, removed the other obstructions, and passed the fossé, the ladders are all to be applied at the same moment. A number of men then mount by them, sufficient to make prisoners of the guard, at one of the gates, which is immediately opened to a reinforcement previously posted near it. This is followed by a larger force, the other gates are thrown open, and the town taken possession of in a similar manner as by a surprise, described above.

If a fossé cannot be passed otherwise than by small boats, with ladders called sambukes, it will be almost impossible to effect an escalade. The garrison ought never to know the real point which it is intended to attack, and therefore false attacks are frequently of great use, as are several attacks at the same time. But it is equally necessary that all this should be done with as much silence as secrecy; for the least noise may discover the whole operations to the garrison, and perhaps frustrate all the attempts.

The most certain method of forcing a fortress to surrender is by famine; but it is at the same time the most tedious, especially if the place be well supplied with provisions, and if it is situated near a river. The taking of a fortress in this way, indeed, is not always practicable, though in certain cases it may be successfully adopted, as when a fortress has a very large garrison, when the inhabitants are very populous, or when it cannot be taken by any other means.

When it is determined to take a fortress by famine, it is blockaded by placing troops round it, at such a distance, as to be without the reach of its guns. The roads, and all passes and passages towards the town, are occupied. The cavalry is stationed on the plains, and the infantry on the inclosed ground. Each of these has its advanced posts towards the enemy, in order to prevent any communication between the fortress and its allies. That no person may pass the posts during the night, constant patrols are sent round; and the greatest vigilance is always observed, where any attempts at communication are suspected. The blockade of a fortress is still more perfect, when it is surrounded by a contravallation composing a connected line, or, what is still better, by a cordon of redoubts.

A town inclosed by impracticable ground, and which communicates with the field only by some roads or scapes, may be more easily, as well as more effectually, blockaded, even by a small corps, than a fortress situated in an open country can be by a large army.

A town partly surrounded with water cannot be blockaded, unless the blockading troops command the water, whether it be the sea, a river, or a lake. In this case, a flotilla, and frequently a fleet, will be necessary to blockade the place from the water side.

To assist the means of consuming the enemy's provisions as soon as possible, a bombardment is frequently of the greatest use, as the enemy's magazines and storehouses may thereby be set on fire, and the inhabitants exposed to much danger. The habitations of the garrison will also be rendered unsafe, and the soldiers exposed to constant disturbance and fatigue.

A bombardment is most advantageously made by mortars of a large calibre, and at great distances, with shells of 12 inches diameter, and large guns, with red-hot balls. The shells used on these occasions should be filled with combustible matter, so as to set on fire the objects near which they explode. For the same purpose, fire-rockets may also be used with advantage. Whatever, indeed, threatens to consume the place, must operate as an inducement to the garrison to surrender, particularly if their provision be destroyed. This may sometimes be effected by spies, or some other secret means, which, of course decides the fate of the place. It ought always to be remembered, however, that the siege is carried on, not as against an inhabited town, but a military post, and therefore the inhabitants are to be spared as much as possible.

At the same time, it must be acknowledged, that this is more the business of the besieged than of the besiegers.

The attack in form, or the regular attack of a fortress, begins, as in the last case, with investing, or inclosing it, with troops. This investment is particularly necessary to cut off the communication between a fortress and its army. Some towns, however, cannot be invested completely, as, for instance, when a fortress is situated on the sea, and possesses a greater naval force than the besiegers. In this case, such a place can always receive sufficient reinforcements, and this alone will very much retard the siege. Those fortresses are also with difficulty invested that are situated on the bank of a large river, the conflux of two rivers, in the middle of woods and hollow ways, at a certain distance from them, or in general on ground which in any way prevents the besieging army from forming a connected circle. It is also very difficult to invest a fortress covered by a large army, or by an entrenched camp. In this case, the investing army has to occupy a very large space, by which its force will be more dispersed, and easily driven back by a concentrated attack from the garrison.

A fortress can either be invested by the army which is to carry on the siege, or by a corps sent forward before that army arrives. This will frequently be of great advantage, unless the fortress is covered by an army, which of course must be driven back before the siege or the investment can take place. It is always to be observed, however, that the investment of a fortress, or the movements and preparations for besieging it, are to be kept most secret, that in the fortress no particular preparations may be made, either in collecting stores, or reinforcing the garrison.

Previous to the commencement of a siege, it is of the highest importance, if possible, to ascertain not only the
in the neighbourhood, in order to determine the strength of the fortress necessary to invest the place. This ought never to be so numerous as to impede the clarity or secrecy of its movements; but at the same time it must be sufficiently strong to encounter the force which may be opposed to it. The besieging corps must also be proportioned to the nature of the ground. If the country be open, a greater quantity of cavalry will be required; but if enclosed, the principal force must be infantry. This corps is to march without any heavy baggage, that it may move with expedition; and that no obstacles may occur from its marching in too large a body, it will: often be necessary to divide it into several columns, which are all to rendezvous at a certain place.

As soon as this corps has been collected, it approaches suddenly to within two miles of the fortress, where every avenue and passage to the place is immediately occupied. In some cases it may be necessary also, to fortify the position, to guard against a sudden attack from a reinforcement of the enemy. As soon as the corps arrives at its appointed place, small parties are sent towards the fortress, to bring away or destroy all kinds of provisions and forage, that the enemy may not profit by them. The same is also to be observed with regard to the cattle, and every thing else which may be of any service to the enemy. If, at the same time, reconnoitring parties can be of use, they are to be sent out; as also parties to drive back any reinforcements that may be sent to the enemy. Should a fortress be situated on the sea-shore, a fleet will also be necessary to blockade it; and, if possible, this must be some days previous to the investment, in order that the fortress may be inclosed every where, as soon as the troops arrive.

The corps which previously invests a fortress, should be careful in preparing the best position for the large army, as well as endeavouring to gain all possible information respecting the place, in order that every thing may be prepared by the time that the army arrives. If, however, the army be sent directly, it will be the business of the commander himself to choose the most advantageous position, and to obtain as much information as can be procured.

As soon as the investment begins, the engineers are to be employed in collecting necessary information respecting the exterior ground surrounding the fortress, as well as itself.

All drawings which may have been obtained of the fortress and the country round it, are compared with the ground, and, if necessary, improved or corrected by actual surveys. If no plans of the fortress can be procured, the works, as well as the surrounding country, are surveyed, in which each engineer has his own work to finish. If instruments, as rulers with dioptras, bousoles, sextants, theodolites, and plain tables, can be used, the survey will be executed with greater accuracy; but where these are not to be had, a single instrument for taking the principal angles will answer the purpose, and the rest may be filled up by the use of the camera lucida, and by telescopes with micrometers, as will be explained in another place. Plans of almost every fortress may now be had, and these plans are corrected by actual comparisons with the works themselves. All particulars, such as the lengths of the flanks, the faces, the curtains, the dimensions of the fossé, and all the outworks, are taken as exactly as possible; and, if necessary, an engineer is to go into the covered way, to examine every thing necessary in this respect. Spies may frequently be of use for this purpose, and from them, after being properly instructed, the best information may be obtained. It is also necessary to ascertain the disposition of the garrison and of its commander, as well as the quantity of its provisions and stores of every kind, and where they are placed, in order to know to what part the fire should be principally directed, or rendered of no use to the garrison. Workmen who have assisted either in building or repairing a fortress, can give valuable information to a besieging army, and therefore every means should be tried to discover them, as the intelligence to be gained from them cannot be obtained from any other quarter.

The camp of the army is to be regularly inspected, in order that every possible improvement may be made for the greater security and convenience of the troops. The magazines and stores of materials and instruments necessary for the siege, are to be made at different places, that the enemy, by their position, may not discover to what part of the fortress an attack will be directed. In entering upon a siege, the principal object of the commander is to see that a good communication is kept up between all the parts of the army, and that the necessary bridges have been constructed. Care is to be taken that these bridges are sufficiently large, and, if possible, there should always be two together, one of which may still be of use, even if the other should be damaged. But in the construction of these bridges, the besieging army should endeavour, as much as possible, to place them out of the reach of the enemy.

Should an army of the enemy be expected, the country round the camp is to be fortified, if it appears advantageous; but care is to be taken not to inclose the army too much, lest its movements should by these means be embarrassed. Single but strong forts appear to be far more advantageous than any other, and are, therefore, more frequently adopted. A besieging army may also be covered by an army of observation, or a corps whose business it is to watch the enemy's movements, and either to protect the besieging army from an attack, or at least to give timely information if an attack is to be expected.

Circumstances must determine, whether the army of observation, or the besieging army, should be the stronger. If the army of the enemy is numerous, the army of observation is to be the larger. In most cases, however, it should, in the first instance, be the smaller, as it may easily be reinforced when necessary. Besides, the besieging army must never be very weak, lest it should fatigue the soldiers too much, and expose them to the attacks of a numerous garrison. To defend them from such an attack, strong but inclosed works, which cover each other, may be raised round the fortress, especially in such places as assure the communication with the different parts of the army, and at a convenient distance for mounting guns.

In making arrangements for a siege, a most important Position of consideration is to determine the position of depots and military stores. These should never be at so great a distance, as to produce any inconvenient delay in procuring the necessary supplies, of which a sufficient quantity must be collected before the siege commences. The first article required is ordnance. With this, therefore, and with every thing necessary to render it effective, the ar-
my must be amply provided the moment it has taken up its position. The quantity that may be necessary in any given case, depends upon the strength of the fortress, and other circumstances, which will be considered afterwards. Next to ordnance, fascines, or rods and brambles for making fascines, are peculiarly necessary. These are either 8 or 12 feet long, and serve to construct parapets, traverses, &c. and sometimes to fill the fossé, in order to pass it. The great number of fascines generally wanted during a siege, may sometimes be procured near a fortress, if sufficient wood of this kind is to be had in its neighbourhood, as they may be transported by land or water to those places, where the depots of these and similar materials are formed.

Gabions are also wanting for the construction of particular works, and therefore it is necessary to have either a number of them in readiness, or the rods of which they are constructed. hurdles made of rods are also used in forming revetments, supporting all excavations of the ground, and covering bridges, which are to be made over small rivulets. It is equally necessary in many cases, to have blinds and moveable parapets, for the purpose of covering the men who use small arms.

In the construction of earth works, a great variety of tools are necessary, such as shovels, spades, fascine knives, saws, hatchets, hammers, drills, &c. and of course a sufficient number of these must be kept in the magazines or depots.

The park of artillery is placed as close to a fortress as possible, always taking care that it be not molested by the enemy's fire. The most advantageous position is when it is covered by a height, or rising ground, and at the same time well protected by the troops from the salis of the garrison, and the attack of an army, to relieve the fortress. The park of artillery is always to be placed in a certain order. The heaviest guns should be stationed in one or two lines, the mortars and howitzers on each side of them, and those of light calibres at the wings. Every article belonging to each piece, including the horses, carts, &c. must be placed in a line close behind it.

The place where the fireworks are prepared, should not be far distant from this park, and the park must be as close as possible to that side where the attack, or where one of the attacks, is to be made. Sometimes, however, it may be placed before a different front of the fortress from that which is to be attacked, in order the better to hide the intention of the besiegers, or to take advantage of a more favourable part of the ground.

The stores of ammunition are to be dispersed in several places, in order that the whole of the powder may not be blown up by any single accident. The buildings erected for this purpose being generally made of wood, and covered by a mound of earth, a ditch, and rows of palisades round them, are to be constructed at such places as are covered from the enemy's fire. These houses for the reception of the ammunition, or of the powder in particular, are to be made so as to keep the powder dry, and must consequently have a good roof; and some openings with shutters, which, in fine weather, may be opened for the free passage of the air. The powder is to be placed on boards, under which the air may pass free, and kept either in barrels or in chests, in the same manner as ammunition chests on the carriages.

The depots for the materials are also constructed near the front where the attack is to be made, that they may easily be conveyed wherever they are wanted. Sometimes, however, to deceive the enemy, or for convenience, a part of the depot may be conveyed to another front, but great caution is necessary on these occasions. It is not proper to place the whole of the materials in one depot, or too near storehouses, lest they should all be destroyed, and their destruction occasion damage to the storehouses also.

Sometimes palisades, and sometimes only a single ditch, is constructed round the depots; and here, as well as round the powder magazines, sentinels are placed, to keep all strangers or suspicious persons at a distance.

The tools and sand bags, or similar stores, may be kept at the depots of materials, but if possible under shelter, that wet, or other circumstances, may not injure them.

The choice of the front to be attacked, will principally be determined by the knowledge that has been procured from the surveys, the weakest being always the most accessible. That side generally is considered to be the weakest which is commanded by eminences, or where the rampart can be hit at a great distance, where the terre-plein is very narrow, the bastions small, the construction or trace imperfect, the defence inconsiderable, the outworks weak, the covered way easily taken, the fossé small and not deep, the revetment damaged, or not of stones, where there are no mines, and where the besieger's works cannot be commanded.

With regard to the surrounding country, a dry plain and open ground sloping towards the fortress is most advantageous. A stony soil particularly retards the siege, as also morish ground. In these situations, the attack can only advance with a very small front, which is certainly very disadvantageous. Hollow ways, hedges, walls, or similar objects, may serve also to cover the besieger's works. If a country be rather low, it is of consequence to know whether it can be inundated, which is a very serious disadvantage. The side of attack also, in some measure, depends on the manner in which the ordnance and fascines can be transported. The fortifications and their strength, however, generally determine the point, when the other circumstances are not very unfavourable.

The next thing to be considered is the plan of the attack, which ought to be such, that all the works shall be conducted regularly, and as few as possible constructed, so that the fortress may be taken in the shortest time. All this is the business of the officer who is to conduct the siege, and who is always present to direct and control every thing on the side of attack. The works constructed by the besiegers as a defence from the fire of the fortress, are in general called trenches. Of these there are different kinds, as approaches, parallel batteries, and traverses.

Approaches are excavations about 3 feet deep, and 10 to 18 feet wide, the earth of which is thrown towards the enemy in order to cover them. The direction of these works is towards the place, but generally zigzag, so that they always approach the fortress in such a manner, that none of them can be enfiladed. They are represented A, A, A, Fig. 1. Parallels are also excavations about 3 to 2½ feet deep, and 20 to 30 feet wide, the earth of which is thrown towards the enemy. They are constructed parallel to the front of attack, as B, B, B. Behind the parapets are made banquettes, for the soldiers to stand upon, as in other fortifications.
FORTIFICATION.

Batteries are places for guns, being mounted on platforms, round which a parapet and a ditch are constructed towards the enemy.

Traverses are similar to the works of the same name formerly described. They consist of mounds of earth, and are constructed, to hinder certain lines from being enfiladed, or to cover troops.

Cavaliers of the trenches are traverses 10 to 12 feet high, constructed on the oblique angle of the glacis, about 10 to 50 feet from it, in order to enfilade the covered way, and to drive its garrison out of it. There are steps behind, by which to ascend them.

The approaches and parallels are conducted according to certain rules, the capital, and its prolongation in the field, being the principal line for the construction of all the works. On a plan of the fortress, these capital lines are drawn, and the first parallel laid down at about 600 to 1000 paces distant from the covered way. The approach or communication between the camp and the parallel is next determined, in such a manner, that the angles of its zigzag are as near to the capital line as possible, and that they form the shortest unenilled way to the parallel. The nearer the trenches come to the place, the smaller are the turns and the angles of the approaches; but the longer time will be taken in approaching the fortress. That part of the approaches which is the most distant from the fortress, is called the tail, and, on the contrary, that which is the nearest to it, the head of the approaches.

The first and second parallel, when a fortress is not very strong, are generally like those represented in Fig. 2; but if the polygon which is attacked be well fortified, Fig. 1, is preferred. The third parallel is generally constructed at the foot of the glacis, and a fourth is sometimes also necessary.

The figure of the parallels, as well as the approaches, being thus laid down, the places of the batteries are next determined. There are three different kinds of batteries, viz. dismounting, ricochetting, and breaching batteries. The former serve to dismount guns, or to damage them, or the parapet before them, that they may be withdrawn, and that the men behind the remaining parts of the parapet may be exposed to the fire as much as possible. Ricochetting batteries serve to enfilade the lines, in the prolongation of which they are placed. This consists in firing with small charges at a particular elevation, by which the shots roll along the inside of the parapet. Breaching batteries serve to make breaches in a work, or to destroy a part of its revetment, rampart, or other inclosure, in such a manner that it may be attacked and mounted with little or no difficulty.

The ricochetting batteries are generally placed at the first or second parallel, in such a manner that they may enfilade the faces and flanks of all the works on the front which are attacked, and even some of the next, as also the covered way, and the works situated before it. They are therefore constructed in their prolongation of these lines. The dismounting batteries are generally constructed at the second and third parallels, or between both; and are parallel to such works as they are intended to annoy.

Breaching batteries are sometimes at the last parallel; but they are still more advantageous when on the crest of the covered way.

The guard of the trenches.

The guard placed for the defence of the trenches should never be less than the garrison of the place. It always remains 24 hours in the trenches, and is generally relieved towards the morning. If possible, this guard is always composed of whole battalions, but never of too large a force from one part of the camp, lest that part should be too much weakened. The sentries in the trenches are to be as numerous as possible; and they always give notice of every shot of the garrison, that every one may secure himself. Cavalry are ordered to cover the ends of the trenches, and to make an attack on the enemy's flank, if he comes out of the fortress. The whole guard of the trenches is commanded by a general; but besides this, the major of the trenches has the immediate superintendence of them, and of the police there. He shows each battalion its place, and gives every commander his proper instructions. He generally has two to four assistants, and is always accompanied by some orderlies, to execute his orders. It is his business, also, to attend the market, to order the provisions, and to see that a proper degree of cleanliness is observed in the trenches.

All works which are to be constructed in one night are previously determined, and proper instructions given, that they may be executed with regularity and the greatest possible dispatch. The engineers, and all overseers of the workmen, are therefore in particular to be well instructed.

The first part to be executed in the plan of an attack is the opening of the trenches, which is done as follows. The workmen, and the men ordered to cover them, or afterwards the guard of the trenches, are to collect in the most secret manner, in the evening, at some place not far distant from that where the attack is to be made. As soon as dark, about 200 to 300 of the best men are sent towards the fortress to draw a line, or to compose a chain of posts parallel to the front of the attack towards the fortress. After these soldiers, who must all be men in whom the greatest confidence can be placed, and who are to be cautioned not to make the least noise, and to see that no one shall desert, follow the engineers, each at the head of a file of workmen. The latter all follow one another, observing strictly the movements of the engineer, who marches on the line which is to be dug out by his file during the night.

The workmen being thus conducted to their stations, they are carefully inspected by the engineer and his assistants, to see that every man is in his place. Each then lays down his fascine, which has previously been given him, and digs in as fast as possible behind it, the fascines being placed by the engineer, or his assistants, in such a manner as to mark the interior crest of the slope of the mount before the trenches, towards the enemy. Every man digs in as soon as possible, to cover himself, in which respect they should be properly instructed by a few words from their leaders, with whom they have to march. Behind these workmen, the rest of the guard of the trenches are to follow, and are placed about 20 to 30 yards distant from the workmen, who form the first parallel.

The workmen should, if possible, consist of soldiers, as labourers give rise to much confusion, without doing more work than an equal number of soldiers. The number of workmen is determined by the length of the line to be dug out, or when great expedition is required one foot, two feet being allowed for each man. Care is always to be taken, however, that there be not so many men as to cause confusion, and therefore it is better to employ no more than are absolutely necessary. All the
of the trenches advances to oppose the enemy. In such cases, cavalry to cut off the enemy's retreat should always be ready. The workmen never should be allowed to disperse, but always be kept in order; and disobedience should be punished on the spot with death, if necessary. Strict discipline, added to a conciliatory mode of informing and instructing the men in their duty, will be of the utmost advantage, and is never to be neglected. The workmen who come at day-break, and even some of the guard of the trenches, may be usefully employed in completing either the communication or the parallel begun in the first night. The next morning after the opening of the trenches, the engineers inspect it, and observe whether the enemy can enflank it. Where this is the case, they order a traverse to be constructed. They also see, that in the parallel the banquettes for the soldiers to fire from are properly constructed, and that the crest of the parapet is as nearly of the same height as possible.

As soon as the first parallel has been finished, the ricochet batteries are constructed. These are placed either in, before, or behind the parallel, according to circumstances. The space between every two guns is generally 24 feet; and between the mortars, about 15. The depth of the batteries is from 80 to 90 feet; and a powder-magazine is generally placed behind them. The guns on such a battery are mostly placed at the ends, and the mortars in the middle. Besides the ricochet batteries, others are constructed to fire at the magazines of the fortress, in order, if possible, to destroy them. Such batteries also may be advantageously constructed, even before the trenches are opened, on heights commanding the town; and mortar-shells filled with combustible matter, or red hot balls, as well as fire-rocketts, may here be of great use, in obligeing a fortress to surrender long before a breach has been made. A battery in the parallel, however, is constructed in the shortest time, and therefore often the best. Its construction is as follows: The parallel is made equal in width to the depth of the battery; the platforms for the guns are laid; the inside of the parapet is finished to the height of the soles of the embrasures, and the embrasure begun; then the parapet is finished, and afterwards also the embrasures, which generally, as well as the interior talus of the parapet, are lined with fascines. The batteries for mortars have no embrasures, but are lined like those for guns. The parallel is in this case conducted round the battery, viz. behind it, in the same manner as parallels are built. The battery has generally a parapet, either at its flanks, or before them, but none behind.

A battery before or behind the parallel is dug out, in quite a different way. The inner talus is determined at first at a proper distance from the parallel and fascines being laid down to mark it out, a ditch is dug out before it, and the parapet constructed in the same manner as directed in field-fortifications, observing the above rules with regard to the construction of the embrasures. The two wings or flanks of such a parapet are joined to the parallel, and serve to secure the communication with it. At the back of these batteries, generally behind a small traverse, a powder-magazine is constructed to contain ammunition enough for two days, or about 200 shots for each gun, and 150 for each mortar.

The men employed to construct such a battery, should be acquainted with the work. These batteries being also constructed during the night, will hardly be complete
the next morning; and therefore they are sometimes constructed only of fascines, or, what is still more expedi- tious, of sand-bags, if they can be had.

It will be also an advantage, if these batteries can be regularly traced, and constructed by such a number of men as do not impede each other in working, but who may always be fully employed during the time they are there. If these labourers can be relieved every two hours, this will forward the work very much, and consider- ably lessen the time usually required.

As soon as the ricochett batteries are finished, and also the first parallel, the fire of these batteries is to begin. Not a gun, however, is to be fired from any of them till they are completely finished, lest they should attract the enemy's fire; as this would molest the workmen, and only give rise to confusion, which might occasion the total destruction of a battery, or the dismantling of its ordnance. When the fire from a battery has once begun, it is to be kept up during the day-time; and if the guns can be levelled at night, the fire should never cease, that the enemy may not be allowed to repair any parts which have been damaged during the day. The fire is to be made at certain intervals, and never two shots at the same time from one battery, that the enemy may always be in a state of alarm. The artillerymen on one battery are divided into certain parties, one of which always serves the guns. An officer has the inspection of each battery, to observe its effect, to correct its levelling, and to make such repairs as may be readily done at the moment, but which, if neglected, might lead to more serious consequences. Every officer, therefore, is to be made answerable for the effect, and the accidents in his battery.

After finishing the parallels and the batteries, those places on the parallel are to be determined from which the approaches shall commence. An opening is then cut in the parapet of the parallel where the workmen are placed to cut out the approaches, covered in a similar manner as in the first night. The soldiers serving to guard these workmen are, if necessary, covered by woolsacks, which they carry with them, and which, being about the height of three feet, will cover a man completely.

The second parallel is constructed exactly in the same manner as the first; but the work being much more dangerous, from its being nearer the fortress, it ought to be executed with the greatest possible secrecy and dispatch. If any part of the parallel has been left unfinished during the night, it should be done the following day, or, at farthest, in the course of next night. After this, the approaches towards the fortress are continued in the same manner as before.

If any point particularly favourable to the construction of ricochett batteries should occur, advantage is to be taken of it, even in preference to those which it had been previously proposed to raise. All sallies made by the garrison are to be met by the guard of the trenches, while the cavalry is endeavouring to cut off the enemy's retreat. The guns on the batteries should always have grape-shot ready, and as soon as an attack of the enemy is perceived, should be fired at those parties against which the attack is directed.

In order to better observe the motions of the ene- my, the ground before the parallels should be illuminat- ed either by fires, or by light-Balls. The third parallel is the next part to be constructed; or if it lies too near the enemy, the dismantling batteries are first to be con- structed. The proper situation for these is either before or on one side of the approaches, or before the third parallel, executed in a similar manner as the ricochett batteries, only that they must be parallel to the faces and flanks. The firing from these batteries, as for- merly observed with regard to the others, is not to commence till they are completely ready in every re- spect; but when once opened, a constant firing is to be kept up, and the guns should be fired at the same time, in order to cause as much confusion as possible in the place.

As the construction of works between the second parallel and the place is very dangerous, an ingenious method has been devised for covering the workmen by means of the sappe. This consists in placing gabions or baskets in the line where a work of the trenches is to be constructed, and filling these baskets with earth, so that they serve to hide the men, and to cover them from the fire of small arms.

There are three different modes of conducting the sappe, viz. the flying sappe, where all the baskets are placed at once by a number of men, and then filled as soon as possible; the half sappe, where all the baskets are placed at once, but filled successively; and the complete sappe, where the baskets are placed successively, so that the man who places one is covered by the preceding one, or by a large bag, or a basket full of earth rolled in front of him. Instead of the basket, or sack full of earth rolled before the men, a blind or board resting on two small wheels, with a thill, is made use of.

The flying sappe may be made by common workmen, and also the half sappe; but, in constructing the complete sappe, men called sappers must be employed, who are particularly acquainted with this business. Of these men, a sappe will require at least four. The first places the baskets, and partly fills them with earth, while he digs a ditch behind them two feet deep, and two wide. He also places small bundles of rods, fascines, or sand-bags, between every two baskets. The three that follow him enlarge the fossé half a foot in depth, and as much in width. These four men take each other places successively, and are relieved every two to four hours by new ones. This work can be conducted by night as well as in the day-time; but not more than from 20 to 30 yards can be completed in one day.

There are also three different kinds of sappes, distin- guished by their figure, viz. the simple, the double, and the covered sappe. The first has baskets filled with earth, or a parapet, only on one side; the second has a parapet on both sides; and the third has not only a parapet on both sides, but also a shell-proof covering.

The construction of the simple sappe has been already explained. The double sappe is constructed by making two simple ones alongside each other; and the covered sappe is made like the double, but as soon as possible covered with rafters, and overlaid with earth. The covered sappe is generally deeper than the simple or double one. The direction of the sappe is also different, being either zigzag, as A, Fig. 5; right-angled, as B; or in the snake- form, as C; or with traverses, as D and E. That which is in form of a zigzag, is used in approaching the third parallel; that with right angles, on the covered way; the snake-form, in tunnels of mines; and that with traverses, in approaching the covered way, or where circumstances require a safe and good communication, which at the same time may in part be used as a place of arms.

In some cases, a third parallel is not constructed, but the attack proceeds immediately from the second paral-
FORTIFICATION.

The fourth parallel is generally constructed like the approaches between both; the former by the flying sappe, and the latter by the ordinary or double sappe, as described above. If a third and a fourth parallel are constructed, it is usual to fix there the dismounting-batteries; but if the third parallel is at the foot of the glacis of the covered way, part of them is before, and part behind.

Should it be found useful to remove the ricocheting-batteries nearer to the fortress, they are placed on crotches, or half parallels. If a fortress has lunettes, no fourth parallel will be wanting, but a lodgement will be necessary, or a place where the soldiers may be covered on them by a parapet. When it is necessary, however, that the sappers should be better supported, and when only a few works of the fortress are dismounted, a fourth parallel, or a place of arms along the salient angles of the covered way, will be required. Dismounting-batteries, however, may sometimes be too distant to reach certain parts of the fortress, and therefore the fourth parallel may be necessary to support them; but, wherever it is possible, crotches before the third parallel are preferred, and the fourth parallel is omitted.

A common covered way may either be taken by an assault, or regularly attacked by the sappe. From the third or fourth parallel, the sappe, and generally the double sappe with traverses, is conducted to about 25 to 40 yards from the covered way, and thence to the right and left parallel, in such a direction as completely to enfilade all the covered way. Here the cavaliers of the trenches are raised to a height of about 12 to 18 feet, with a traverse at the end, to prevent it from being enfiladed from the covered way.

This cavalier is generally raised by gabions, of which either four or five lines are in the lowest row, one less in the second, one less in the third, and only one in the fourth or uppermost row. One row after the other is filled with earth; but a second row is never to be begun till the first is completed. Sometimes a more simple kind of cavalier of the trench is used, having only one row of gabions, each above the other. To mount these high parapets, stairs are raised behind them by means of fascines. The attack being generally directed against the salient angles of the polygon or front, and in most cases the heads of the sappe being equal in number to the angles of a front, viz. the two bastions and the demi-lune, it will be necessary to conduct these three attacks by the sappe towards the covered way, all on the capital lines of the salient angles. As soon as the attack has arrived at the salient angles, the cavaliers of the trench are to be constructed, to the number of at least three pair. As soon as these are finished, they are filled with soldiers, who keep up a constant fire along the covered way, so as to prevent any of the enemy from remaining there with safety.

In the meantime, the sappers are continued towards the palisadoes of the covered way, till they are not nearer distant than from six to nine yards, when they are carried to the right and left, parallel to the covered way, till they meet in the re-entering angle before the places of arms. If the enemy be still in force in the places of arms, he is to be driven out by stone mortars and shells. But if this fire should not induce him to quit the places of arms, and if they are very strong, and not to be taken without a breach or an opening made in their rampart, then breaching batteries must be raised against them. These are made like the dismounting-batteries, but more covered from the enemy's fire either by traverses or higher parapets.

If the place of arms can be attacked by surprise, this may be done as soon as the sappe along the palisadoes of the covered way, or lodgement on the crest of the glacis, is finished, and as soon as it is ascertained that none of the enemy are hidden behind the traverses in the covered way. The place of arms being taken, it is usual to construct a lodgement there, or a place where the soldiers may be covered from the enemy's fire, and can oppose to him a front along all the works. Another mode of attacking the covered way is by assault. This, however, cannot be undertaken till all the guns in the fortress are silenced, and the enemy's works there can be assaulted without making a breach. But as the assault is generally attended with a considerable loss of men, a vigorous attack on the covered way is mostly preferred. However, when it is determined to bring the siege to a conclusion in a short time, or when the works of the enemy are very weak, and when the chance of success is probable, the assault is to be undertaken. This attack is usually made by volunteers from different regiments, and their way is cleared by pioneers or carpenters, who hew down the palisadoes, and remove all other obstacles. When such an attack is resolved on, it is to be made at day-break: the palisadoes are cut down, the soldiers enter the covered way, put every one they meet to the sword, and proceed directly to the place of arms, which must also be taken. If this can be done by surprise, it is always more advantageous. The lodgement on the place of arms is made as soon as possible, and covered with fascines, wool, or sand-bags. Wool-sacks certainly are of the greatest advantage here, as they may be easily conveyed from one place to another, and form a good parapet for the fire of small arms.

If the sappe on the glacis, along the palisadoes, or lodgement on the crest of the covered way, has not or the covered way been traversed, it may be made to serve as a parapet. The attack should always be undertaken as secretly as possible; and in order to surprise the enemy, and where a lodgement on the crest of the covered way is to be constructed, this attack is to be made at midnight, that the lodgement may be finished before day-break.

During the time the lodgement is making, and which is directed by the engineers, the men who made the assault lie down and cover themselves as securely as possible from the enemy's fire, that they may be ready to oppose the enemy if he should return, and also to protect the workmen.

As soon as it becomes light, these men retire into the lodgement, if it be ready; if not, to the next part of the trench. The lodgement is finished, if possible, the next day, if the enemy's fire is not too destructive to prevent the workmen from going on.

To prevent accidents, the men who storm the covered way are to search for the heads of small mines, and if they discover these, or any other contrivance invented by the enemy as means of annoyance, they are to be instantly destroyed.

The attack of a covered way by mines being the most tedious, is only to be undertaken when other methods fail, or when the enemy uses mines also.

The mines must, in this case, be so constructed, that the largest globe of compression may easily burst, and
that a proper tunnel or excavation may be made by it for constructing a lodgement.

The first method of attacking by mines, is to make a subterraneous well towards the covered way, of about 4 feet square, and then this has been carried to a proper distance from the third parallel, a place it to be formal for depositing the charge; the mine is then to be filled, blocked up, and fired. Experience is the best guide in determining the quantity of powder to be used.

In this manner the work proceeds, till it arrive near the covered way. As soon as a tunnel of a mine is formed, a lodgement is directly made there, that the troops may advance and take possession of it, and thus gradually approach the fortress. If some of the enemy's mines and wells are met with, or if his miners is heard, a mine is directly to be filled and burst, before he has time to do so with any of his. But should the miners be destroyed by the enemy bursting his mines, new ones must be begun, which there is reason to expect will be more successful, as the enemy will then have no more mines at his command.

If the miners should chance to meet those of the enemy, a subterraneous engagement will ensue, in which smoke-balls, for producing a poisonous and suffocating smoke, may be of use. If they succeed in driving the enemy from the mine, a large one is to be made, and the whole blown up as soon as possible. In all cases it will be necessary to keep the most accurate drawing possible of the progress of the mines, executed from actual surveys.

If one of the enemy's wells be discovered, it is to be filled at certain spaces with quantities of powder; these are to be blocked up properly, and the whole exploded, in order to form a lodgement or an approach, which, after bursting a mine, is finished by the sappe. In mining, it will sometimes happen that the ground is not firm enough, or that springs are met with, and that the miner is unable to proceed, in which case new wells are to be dug out, as before. The depth of these wells should, if possible, be 20 to 30 feet below the ground. Large mines are always very advantageous for the besieger, as they favour the construction of lodgements; but small mines, which are not seen on the surface of the ground, are of the greatest advantage to the besieger, as they are of no use to the enemy, but serve to destroy his works, and to obstruct his advances.

The mines used to take the covered way may also be applied in destroying the traverses, and even the places of arms.

As soon as the covered way is taken, and the lodgement on it finished, the construction of the breaching batteries is begun, and, if possible, in such a way that the angle of the shoulder may be struck by the balls in a perpendicular direction. But if this cannot be done, and if the front has a large demi-lune, the breach is to be attempted, 10 to 15 yards from the angle of the bastion.

The breach in the ravine is made so as to destroy the intrenchments formed on it, at the same time that the breach is made; or if this is not possible, the breach is laid 10 to 15 yards from its salient angle.

Breaches in counter-guardis, lunettes, manteaux, &c. are laid as in the demi-lunes, or nearer to their salient angles.

At the same time, with these breaching batteries, dismounting batteries are also constructed for destroying the flanks. The breaching as well as the dismounting batteries are constructed by the aid of the sappe, in a manner similar to that before described. But sandbags and wool-bags are here also of considerable advantage, and where they are to be had, they should always be used. The fire of these dismounting and breaching batteries is begun as soon as they are finished, but never sooner, that they may not be exposed too much, while they are in an unfinished state. The shots of one battery are fired at the same time, and directed at about one-half of the height of the revetment. Every embrasure is to be advantageously blindered with a gabion, a wool-sack, or a bundle of fascines, while the men are charging the guns.

During the discharge of the guns for dismounting the rampart and making breaches, the passage into the covered way is to be formed by the sappe, and from that the way to the fossé is made, either by a subterraneous passage, or by the double and covered sappe. When the subterraneous passage is formed, it is to be lined and covered with wood, and carried on to the revetment of the counterscarp. This is penetrated either by a small mine, or by piercing it, and making an entrance, which is to come about two feet above the surface of the water, or as much above the ground of a dry fossé.

The passage over the fossé is differently constructed, according to the nature of the fossé. A dry fossé may be passed by a double or by a covered sappe; a wet fossé, where the water does not flow, by a fascine dam; and a fossé where there is a current, by a kind of fascine dam constructed on scaffolds to let the water pass by. The sappe over a dry ditch is made, as described above, either by mines, or like a double or a covered sappe.

The dam over a wet ditch, where there is no current, has two parapets; one at each side, if the enemy's fire is to be feared in passing the fossé, even though all his guns at this time should be dismounted, or at least unfit for use on the attacked side. The dam is regularly and successively constructed, by forming a layer of fascines, and covering them with earth, and continuing with this till it be sufficiently high, then the parapet is constructed, a new part begun, and the work proceeds thus till the whole is finished.

A dam over a fossé which has a current, is more difficult. The first thing is to try whether the current cannot be stopped, or the water let off. When this is impossible, the scaffolds are placed gradually, the intervals are filled with fascines, the upper part formed also with fascines and earth, and then the parapet constructed. The weak parts are then strengthened, so as to guard as much as possible against all accidents.

The last part of such a dam generally is a bridge, which is constructed of long rafters, and covered with fascines and earth like the other parts of the dam.

When the dam or passage over the fossé is completed, the assault is determined upon, and secretly and unexpectedly undertaken an hour before day-break. The outworks generally are taken before the bastions can be assaulted, but sometimes, and as often as circumstances allow it, the outworks are either passed, or the bastion and the outworks attacked at the same time. As soon as a practicable breach has been made in the ravelin, a sufficient number of volunteers assault the work, and in general soon get possession of the place. If the garrison retires to an entrenchment, that also must be immediately assailed; but if this cannot be done, the soldiers lie down, and cover themselves with wool-sacks, till the lodgement is formed by a number of workmen ordered for this purpose to accompany the soldiers who make the assault.
FORTIFICATION.

If this lodgement be practicable for receiving troops, it is directly to be occupied, and this must be done by day-break at latest, that the men may not suffer too much from the fire of the enemy's small arms. Such lodgements are most expeditiously formed of sand-bags, wool-racks, &c.

If the assailing army has been repulsed, or if the lodgement has not been made in such a way as to be occupied by the men, and if they have been compelled to leave it, the attack is to be renewed as before. If any apprehensions are entertained of the enemy's mines, it will be necessary to send the miners to lay a mine and burst it, in order to form the intrenchment or lodgement there with more ease, or to force the enemy to leave it before the assault has taken place.

Works in the gorge of an outwork or a bastion, will frequently prove great impediments to the besiegers, and therefore they should be molested by shells, or be undermined, and thus rendered assailable. But if neither of these be sufficient to force a work to surrender, a breaching battery is to be constructed before the lodgement made on this work, in the same manner as before directed, and then a regular assault is to take place, as observed of outworks or a bastion. A fortress which is taken by assault is sometimes given up to plunder; but this very seldom happens in modern times. If, however, it should be the case, and the assault has succeeded, the gates are immediately to be opened, and patrols of cavalry are sent to preserve order. This last precaution becomes more necessary if the enemy retires to the citadel. If no plundering is allowed, heavy contributions may often be raised, and divided among the soldiers.

If a fortress has capitulated, or surrendered by a treaty, one gate is directly to be occupied, but no person allowed to pass without a proper passport. The articles in the treaty and capitulation are executed, and an inventory made out of all stores, provisions, &c. taken possession of. Of these articles, farther notice will be taken in a subsequent part of our subject. Should the garrison, however, by some means or other, force the besiegers to raise the siege, it is done as secretly as possible. The stores of ammunition are all fired away, or left behind; and the guns of light calibres continue their fire, till all the large ones are withdrawn. The former are then brought off, followed by the garrison on the trenches. All that is left is then set fire to, or destroyed, and pieces of ordnance are spiked and rendered totally unfit for use.

The siege of a fortress situated on a mountain is more difficult than if situated in a plain, as the trenches will frequently be so completely commanded from the fortress, as to render the progress of the works on that side impracticable. In this case those parts must be attacked, where advantage can be taken of ravines, hollow ways, or other local circumstances.

Fortresses situated in a moor, or surrounded with water, so as to communicate only with firm ground round it, by dams or small necks of land, are to be attacked on those parts, and a sappee may be conducted on them, so as to approach covered. To make the parallels longer, or to construct batteries upon, or by the side of these dams, saxes filled with earth may be usefully employed; the passages made over these earth-sacks are covered with boards, or fascines, to ensure a firm footing, and that they may be fit for carrying guns. If the water round a fortress be so deep as to carry boats with guns, either these, or batteries built on rafts or floats of wood, are to be stationed at proper places to bombard the fortress. This is also to be done from several points, where the fire can reach the fortress, in order, if possible, to destroy the stores and provisions there.

Fortresses situated on a stony or rocky soil are difficult to be attacked, and the works round them can only be constructed by earth or wool-bags, and by fascines.

Should a town have a citadel, it will be necessary to consider, before commencing the attack, whether the citadel or the fortress is to be assaulted first. In all cases where the citadel commands the fortress, and where it will not be much more difficult to attack it than the town, the first efforts should be directed against the citadel, and not against the fortress. When a fortress is to be attacked in form, the operations may frequently be shortened, by forming a brusque attack or beginning with the construction of the third parallel as the first works of the trenches, and afterwards making a communication from that to the camp. The attack proceeds then regularly, and ricochett batteries, as well as dismounting and breeching batteries, are constructed as before.

The last method of attacking a fortress is by tirsailleurs. Batteries are constructed at a great distance, and mounted with mortars and guns of large calibres. As soon as these batteries have begun their fire, a chain of tirsailleurs is formed all-round the fortress, who approach the works, covering themselves by the excavations and elevations of the ground, or by the pits, ditches, hollow ways, ravines, trees, houses, walls, hedges, &c. &c. From such places they fire at every one who appears on the rampart, or any other of the enemy's works. The tirsailleurs should always take aim, and avail themselves of every circumstance that may direct their fire with effect. In general, they have little to fear from the fire of the garrison; but, if necessary, they are still better covered, by giving them wool-bags, or by constructing a parallel for them, and also by combining their operations with a brusque attack. These tirsailleurs always approach the fortress by degrees, and inclose it as much as possible, until the covered-way can be taken by storm; and the attack is afterwards continued as circumstances may require.

The men ordered for this attack are to be properly instructed in their duty, and besides, rewards are promised to them on their executing it completely. They always retire at night, or when dark, and appear before day-light, in order that their fire may begin with the dawn of day. While this attack of the tirsailleurs is going on, the ordnance also endeavours to annoy the enemy; and ricochett batteries may be constructed to assist the others. These, however, may be brought closer to the fortress, to increase their effect. This method of attack was first practised by the French in the revolutionary war, with great success; and, combined with the attack in form, it certainly does appear well calculated to force an early surrender.

Having traced the progressive operations of the besiegers from the first opening of the trenches to the surrender of the place, we come now to consider the defensive measures adopted by the garrison.

A fortress, where a siege is to be expected, should always be put in the best possible state of defence; by repairing all the works, placing the palisades, constructing the necessary traverses, and, in short, neglecting nothing which may render it stronger. The ravelins should have scarpis and weak fronts, strong places of arms, and lunettes, all of which are to be ex-
FORTIFICATION.

Executive of the siege commences. A sufficient quantity of ammunition, ordnance, materials for repairs, and other military stores, is also to be provided. Entrenchments are to be constructed, and the ordnance partly mounted. Powder magazines are to be formed in secure places, and at proper distances from each other, and such fire-works prepared as may be used during the siege.

Inhabitants how to be treated.

Provisions to be collected.

Precautions against a surprise.

Strict discipline to be observed.

How to repel a surprise.

A surprise is always very useful in the event of a surprise, as the troops may collect there, and act against the enemy with more regularity, and with a greater chance of driving him back. Besides, the possession of a town commanded by a citadel is of very little use to the enemy. But should a surprise have taken place, all the troops are to collect at the spot fixed on, from which they proceed to join on the places to be defended. As soon as the greater part of the garrison is collected, detachments are sent to the different streets to capture the enemy, and particularly to reinforce the gates, to prevent a greater number from entering the town. The enemy may thus regularly be repulsed, and even a part of his troops be cut off.

If the garrison, however, is too weak to defend itself, it must retire to the citadel, or look out for a safe retreat. Should the inhabitants take part against the garrison, it will be necessary to set fire to the town in several places. But the greatest attention of the commander is necessary to prevent disorder, as this alone will increase the loss more than any thing, and therefore the necessary instructions are to be previously given, that every one may know his place and his proper duty in case of a surprise. In an open attack, the defenders have great advantages over the assailants, and these being duly considered, and properly represented to the garrison, will contribute much to increase its spirit. When such an attack is expected, great care is necessary in making the most judicious arrangements, both with regard to the works that are to be defended, and the number of men requisite for that purpose.

The plan of the enemy must if possible be ascertained by spies, or some other secret means. When the side of the attack is known, fire and light balls are to be thrown in that direction, and, when the enemy is perceived, he must be opposed with grape shot.

As soon as he arrives in the fossé, grenades, shells, and other artificial fire-works, are to be used. When at different points, he attempts to mount the rampart, large trees, and other heavy bodies, are to be rolled over the parapet upon him; and should he arrive, bayonets must be used. If he succeed in getting possession of the rampart, he must be charged by the cavalry, and reinforcements of infantry. Should these also be repulsed, the streets are to be defended, and finally the signal given for retreating to the citadel, which should be done with the greatest possible order.

The defence against a blockade, consists in having plenty of stores and provisions, and magazines where they can be safely preserved. All unnecessary persons are to be sent out of the town; the inhabitants that remain, are to be ordered to lay in a sufficient stock of provisions, and premiums promised for the importation of these articles. Such provisions as are in the place must be properly distributed, that they may not be consumed in a useless manner. Should provisions be scarce, the houses are searched, to know what stores the inhabitants may have, of what a part may be taken for money if necessary. Should money become scarce, some of it may be stamped to increase its nominal value. Copper may be coined, or loans contracted. The garrison besides should have safe habitations; and sometimes sorties or attacks must be made, with smaller or larger parties, against the enemy, in order to annoy him, and to procure provisions. If, however, these sorties prove unsuccessful, great care is to be taken that the enemy does not penetrate into the fortress with the troops who make the sortie.

The defence of a place against an attack in form, is subjected to greater difficulties. The first thing necess
The garrison is then properly divided, that no part may have more labour to undergo than another; and never should too large a number be ordered on duty, unless the fortress has a very large garrison. A journal is to be kept, in which every circumstance that may occur during the siege is entered.

If every thing has been prepared, and the enemy's engineers should make their appearance, they are to be received with a discharge of grape-shot or balls. This only, however, in case of their approaching in parties, as this sort of ammunition is never wasted on a single man. Small calibres are generally used for this purpose, to prevent the besieger from becoming acquainted with the range of the ordnance. That the engineers may not approach during the night, small posts are placed before the covered way. The commandant also takes care to keep up a communication with the army, or the neighbouring fortresses, that, if succours arrive, they may be able to enter with facility. Should any parts of the enemy's camp lie within reach of the fire of the garrison, it is to be cannonaded as soon as finished, but not sooner. To prevent the enemy from getting acquainted with the weakest side of the fortress, a great smoke may be made, by burning straw, or firing smoke-balls of various kinds, so as to conceal several fronts. Sometimes also false drawings, or similar devices, may serve to give the enemy an erroneous idea of the strength of different fronts.

The side which the enemy is determined to attack, may be known from the situation of his depots of materials, and from seeing the engineers constantly at work. This front, in particular, is to be put into a proper state of defence, the country before it being illuminated during the night by fire-balls, and outposts must be placed before the covered way. Small works are here also useful, in making the besieger begin his first parallel, as well as all his others, at a great distance. When it is necessary to leave these works, to prevent the enemy deriving any advantage from them, their parapets are to be sprung and destroyed by small mines.

When it has been discovered, by means of spies or light balls, when and where the enemy opens his trenches, a constant fire must be kept up, in order to disperse the workmen. Next morning the engineers are to survey the enemy's work, and a fire opened on such parts of them as can be enfiladed. In the beginning of the siege, a strong fire ought to be kept up, to hinder the enemy from completing his works; but afterwards it is directed only to those places where it may be of the greatest use, particularly where the enemy has constructed his batteries.

Should the enemy's batteries be finished, the guns are rather to be withdrawn than destroyed; but if one of the enemy's batteries can be dismounted, all the force is at first directed against one merlon, and then against the others successively.

Such parts of the fortress as have been damaged must be repaired during the night, that they may be in a proper state for service the following morning.

Should the enemy's parallel come so close to the covered way, that the fire of small arms can reach it, riflemen should be placed there, to fire at every one who may approach the trenches, particularly when the engineers or officers appear. The fire of the riflemen should also be directed against the head of the trenches, or where they are not quite finished, as also where batteries are to be erected.

For the same purpose also, small pieces of ordnance, and in particular small mortars, placed in the salient breaches, may be used with the greatest advantage. Counter approaches are sometimes used, and they are of no benefit, it being ridiculous to suppose that a garrison can, with any advantage, besiege the army by which it is itself besieged.

Another means of defence against a siege are sorties or sallies, for the purpose of procuring provisions, opening a communication with the army, or attacking some part of the enemy's works. They are undertaken sometimes before, and sometimes after the place has been invested; and they differ in the strength of the parties employed, according to the object in view.

Sorties against the enemy at some distance from the fortress, are sometimes liable to be cut off, and therefore only to be undertaken when the retreat can be secured. As such sorties also generally cost a great many men, they should only be undertaken when there is a fair prospect of obtaining some particular advantages, and where the garrison is so strong that a sufficient number will remain to defend the fortress properly.

Sorties which require a strong force, should never be undertaken unless they have a particular object in view, and then they are to be made by a sufficient number of troops to execute it without difficulty. Particular circumstances sometimes determine a garrison to make a strong sortie; but it is never in this case to be done if the men could afterwards be of greater service in the defence of the fortress. What relates to the execution of these sorties, the nature of the ground, and the different movements, will be farther illustrated under other articles.

Small sorties are generally made by parties of about 20 to 30 men, who secretly leave the covered way, and attack suddenly with great noise. They then destroy every thing belonging to the trenches, or set fire to them, spike up the enemy's guns, overload them, &c. for all which purposes they are provided with the necessary assistance of workmen, tools, and materials, taking care always to retreat as soon as the enemy's reinforcements arrive. These little attacks are particularly useful after a mine has been sprung, before the garrison of the trenches has recovered from its fright, and order restored.

The most advantageous time for attacks is midnight, or towards morning, when the troops in the trenches are still fatigued by their labours during the night.

But no sortie should be made with two large a force, lest the enemy meanwhile make a successful attack on another part, while the largest force has been drawn farther away from the fortress. In general the number of men employed in a sortie should never exceed...
FORTIFICATION.

A small garrison should never make a sortie with more than one-fourth of their number, unless it be to open a communication for retreating with all the garrison. The retreat from a sortie is always to be covered by some infantry and cavalry, but particularly by riflemen in the covered way, and by ordnance mounted on the ramparts.

The defence of a common covered way can only be made by soldiers being placed there, and covered by the traverses. They keep up a constant fire towards the enemy’s works, particularly during the night, and towards the head of the sappe, in order to prevent him effecting his lodgement along the covered way. If there is reason to suspect that a forced attack will be made on the covered way, it will be advantageous to place a greater number of soldiers to defend it, as also to make small mines under the traverses, and even under the glacis, where the enemy has to construct his lodgements. The heart of these mines should be close to the re-entering angle. If the enemy has driven the garrison out of the covered way, and it has retreated from one traverse to the other, and to the places of arms, the mines are sprung gradually, and also those under the glacis. But if the enemy has entered in a disorderly manner, he is to be attacked, and if possible repulsed.

The soldiers in the places of arms, as well as some small guns placed there, will always most beneficially direct their fire upon the enemy, and be particularly useful in taking him in flank, or in firing at him when advancing or retreating. Should the covered way be attacked by the sappe, the construction of the cavaliers of the trench is particularly obstructed by a constant fire from the covered way.

A polygon, where there are counter mines, may always be defended longer than where there are none. If the enemy should not begin to mine, the garrison must endeavour to spring theirs under some of his works, particularly his batteries. This will retard not only his advancing from the third parallel, but also force him to commence mining. The most favourable moment for making an attack on the enemy, is after a mine has been sprung, and therefore a sortie is then to be hazarded.

If the enemy has begun to mine and to dig a well, it will be necessary to discover the place, and immediately spring a mine under it. This is repeated as often as he can be discovered.

The near approach of the enemy’s mine may sometimes be detected by placing a drum on the ground, and scattering a few peas on its top. If the miner be very near, his digging will communicate a tremulous motion to the drum, and of course to the peas. When this takes place, the countermine is immediately to be sprung. If the enemy’s well is discovered before the countermine is ready, the former may be filled with the poisonous smoke of fire-balls. The miners ought always to be armed with large pistols, to defend themselves should they fall in with those of the enemy. In this case subterraneous fortifications will also be necessary.

If there be any small works in the salient angle of the covered way, they will keep the enemy at a certain distance as long as they can be occupied, and therefore this is done till he is ready to assault it, and even then they are not to be left, unless it be found impossible to defend them.

An avant-fossé that is full of water, is frequently of great use, as it prevents the enemy from passing it, or constructing a bridge, as long as there are guns to enfilade it.

A second covert way, particularly if it has a strong work in its re-entering angle, is also useful, and keeps the enemy some time longer; but in defending it, care is to be taken that it is not surprised, when the covert way before it is taken. In order to deceive the besieger as much as possible as to the number of ordnance in a fortress, the fire should be directed principally at the first parallel, at the batteries, and at the head of the sappe: in all others it may be slackened, which will induce the enemy to believe that many of the guns are dismantled.

When the enemy approaches the covered way, and is endeavouring to construct his lodgement there, or to effect his passage over the fossé, the guns that have been preserved are to be opened upon him, and an unremitted fire kept up as long as they are fit for use.

Such works as have sustained much injury, are always to be repaired with all possible dispatch, and ordnance is to be planted behind them to be ready for use. If the enemy has taken possession of the covert way, it will be necessary first to spring the mines there, in order to throw him into confusion, and then to attack him and drive him back.

The defence of the fossé is the next most essential part; but cannot be of long duration, for if the counter-scarp is lost, all is lost. Still, however, a gun, or several riflemen, will be of the greatest use to hinder the passage of the fossé; and sallies also may be made if the ditch is dry. If the fossé be wet, fire-machines will be useful to set the fascines of the enemy on fire; and where the water can be let in and out at pleasure, the enemy may be harassed for a considerable time. Even when he thinks himself master of the fossé, his works may be destroyed by a sudden inundation. The besieged always have great advantages when the enemy is among their works, as confusion is likely to take place. In such circumstances too, a sally may be successfully made.

The defence of the outworks, after the enemy has made a breach, is either attempted on the top of the breach, or from the work in its re-entering angle. In the first case, the enemy is to be attacked by small mines, artificial fire-works, and rafters thrown down upon him, care being taken that he does not overcome all these impediments, and penetrate the sections, where otherwise a good defence might have been made. As soon as the enemy has taken an outwork, and begins to construct his lodgement there, a small gun, or some riflemen, are to molest him constantly. Mines are also to be sprung under his lodgement, or any work where he has constructed a lodgement, an attack being always made upon him after every explosion.

Should an outwork be countermined, and the enemy begins a subterraneous war, he must be opposed as formerly directed.

If the enemy’s well is discovered under a work, it may be filled, as we formerly observed, with poisonous smoke; and his miner be killed by grenades and shells thrown in the fossé, or by others hung before his well, and afterwards burst.

If, after the enemy has taken an outwork, he can be again dislodged, all endeavours must be used for that purpose; and to effect this, the most probable appear to be, to make a sally after bursting a mine, and to destroy his communication over the fossé.

The defence of the rampart so often neglected, though great labour is frequently used in constructing it, is the last part of the defence of a fortress. The assault here
FORTIFICATION.

Attack and Defence of Permanent Fortifications.

may be sustained, when a strong section is to be had, or when there is a retreat to a place, where the garrison may wait till a convention be concluded, or succours arrive. Sometimes, however, circumstances do not allow the garrison to wait an assault, and, in this case, the commandant capitulates, either to save the lives of many, or to prevent the inhabitants from being plundered. When the defence of the rampart is resolved on, the same rules are to be observed as in the defence of outworks.

Defence against the assault.

Circumstances must determine whether the enemy is to be opposed on the breach, or attacked from the section. The latter is to be preferred, unless there is every reason to believe that the former will prove successful. A sally at the time of the assault may sometimes be useful; but is always in such circumstances to be undertaken with caution.

A fortress with a citadel may be defended as long as possible; and when the enemy has penetrated by an assault, and when every thing necessary has been sent into the citadel, the troops are to withdraw to it, taking care that the enemy does not enter along with them. Rather than run any risk of this, indeed, part of the garrison is to be shut out. If the commandant is at last convinced that the fortress must surrender, he orders the chamade to be beaten on the attacked front, or he sends an officer to the enemy, to propose an armistice. If this be granted, he sends some intelligent officers to the enemy to conclude a capitulation, or the capitulation may be concluded in the town, the enemy sending two or more officers, with proper powers and instructions for that purpose.

The garrison on capitulating, either has a free retreat, and immediately marches out, or it leaves the fortress and surrenders on the glacis, either as prisoners of war, or under an engagement not to serve against the country of the besieger or his allies during a certain time. The officers and men generally keep their luggage, and the former also their swords. The place to which they shall be conducted, how they shall be paid, and when exchanged, are all agreed upon in the articles of capitulation.

The prisoners of war and deserters are, if possible, kept; but are also sometimes delivered up to the enemy. The magazines are either emptied and destroyed, or delivered up. The works of the fortress, and the keys of all places, are given up. One gate is generally placed in the hands of the besiegers at the time of the ratification; but no person is allowed to pass who is not provided with a proper passport. The garrison has to leave the town on a certain day. All points which may not be well explained, are to be construed to the advantage of the garrison. A citadel near a town makes sometimes an alteration in the articles; as if the town is given up, the citadel is always retained. Sometimes it is stipulated, that if, during a certain time, no relief arrives, the articles of the capitulation are to be fulfilled. But the most advantageous points and articles are generally proposed to the enemy, and adhered to as long as possible; and therefore every commandant ought to be prepared with articles of this kind adapted to his case; for the sending copies of articles of capitulation for approval or rejection at the close of a siege, is merely done with the hope of gaining time. The enemy will always return an answer, and by this it may be known what articles are to be expected.

To see the terms of the capitulation carried into effect, two officers of high rank are given as hostages, who are set at liberty as soon as the capitulation is fulfilled. The non-execution of any of the articles of capitulation on either side, will only cause reprisals, and these frequently are attended with bad consequences. To prevent this, every thing is determined as minutely as possible, and all articles are then strictly fulfilled.

Various methods may be employed, and in some cases successfully, for obliging the enemy to raise the siege, particularly if the garrison acts in conjunction with an army. The army may in these circumstances either attack the enemy, or cut off his provisions and succours, which seldom fail in forcing him to raise the siege. The army may also attack either the besieging army, or the corps of observation; but this should always be done with the knowledge of the garrison, in order that it may act in concert.

Sometimes a siege may be raised by the exertions of the garrison alone, as by sallies judiciously conducted, and mines well applied; but by whatever means this may be effected, the garrison ought to make sallies during the night in which the besieger withdraws his ordnance, for the purpose of annoying him as much as possible.

Should a fortress be attacked by tirailleurs, as was explained in enumerating the different modes of attacking a fortress, the best defence will be made by small guns placed in the most salient parts of the works for firing grape shot. Riflemen will also be advantageous employed in attacking them, in the same manner as they attack the fortress. When, however, whole troops of the enemy's men are perceived, guns of a small calibre, charged with grape shot, are chiefly to be depended upon. In other respects, the defence is the same as has been already described.

Defence of the citadel.

On the Attack and Defence of Field Fortifications.

The attack and defence of field fortifications is neither so difficult nor so tedious as that of fortresses.

The arrangement of a whole fortified line is as follows: The camp is generally about 400 paces from the lines. The works are usually occupied two men deep, or with two rows of soldiers; the reserve is placed about 100 paces behind it, in order to give support wherever it may be required; and each battery, as well as each squadron and battalion, has its particular place assigned to it. As soon as the alarm-gun is fired, each man must repair to his post as speedily as possible, completely armed, and ready to act.

To secure the fortifications from a surprise, the light infantry posts are about 5000 paces before the works. If, however, the country is inclosed, or woods are near them, the chain of these posts is thicker, viz. about from 500 to 2000 paces distant from the works. Among these posts constant patrols are sent round. If the enemy is close to the works, at least one-half of these posts must always be under arms. During the day, the same is to be observed by all the outposts, and sometimes also by all the men in a camp. The arrival of the enemy is generally known, as in the case of fortresses, from deserters, spies, &c. When the enemy approaches, the outposts are to engage him, and to keep him as long as possible at a distance, that the troops may have
time to form. The works are then quickly occupied, the artillerists having previously made themselves acquainted with the distances before the works, that they may level their guns accordingly. The guns in the salient angles begin their fire as soon as the enemy is within reach. If a few guns, by advancing, can take a part of the enemy's force in flank, it will be of great consequence. The infantry begin their fire when the enemy is at about 300 paces distant. As soon as he has sufficiently near the works, the guns are to be dismantled, and their places filled up by infantry. But if he should advance to the ditches, artificial fireworks are made use of; and if he ascends the parapet, a brisk fire must be kept up, followed by a charge with the bayonet, and the first rank standing upon the parapet. Should the enemy have penetrated in any part, the cavalry are to charge him before he forms. The reserve must now pay the greatest attention; and the horse artillery, as soon as the enemy has penetrated, will be of great use in throwing him into disorder, of which the cavalry must take advantage. In the mean time, the infantry forms, and returns to the attack. If the enemy should be compelled to retreat, he is not to be pursued too hastily, lest, by rallying, he should succeed in entering the interior intrenchments along with the troops that retreat thither; but the ordnance must at this moment play upon the enemy with all possible vigour.

Defence of single forts. The defence of single forts is almost the same as above mentioned, except that the garrisons have to encamp in their respective forts; and that the single forts are supported by the ordnance as well as by the infantry, both being drawn up in line behind them. The artillerists is brought wherever the principal attack is made, and must be employed with the utmost effect. Should the enemy be repulsed, or be thrown into disorder at any point, the cavalry suddenly advances, charges directly, and pursues, but always keeps closed, and in good order.

If the attack of the enemy should be undertaken in the night, then the country round the fortifications is illuminated by light-balls or by fires, for which purpose wood must previously have been brought thither.

The troops should always be acquainted with what they have to expect from the works, and how they can turn them to the best account in their defence. The moment of the attack is intimated to them, as also the danger to which they will be exposed if they should be defeated; and, on the contrary, how much they will gain if victorious. Convince a soldier that his honour is at stake, and the work which he is to defend will be easily fortified.

False alarms, &c. To keep the men always on the alert, a false alarm may sometimes be given; but care must be taken that this is not too frequently resorted to, lest they neglect to be prepared when a real attack is made.

The attack of fortified lines should not be undertaken before an accurate knowledge has been procured of the works which the enemy has constructed to oppose it. The attack, as before observed, is most advantageously made an hour before day-break. The fortifications should, if possible, be taken in rear, by going round them, which may be most favourably done by a night-march, provided there be no danger of mistaking the road, which might lead to great confusion, and disastrous consequences.

Attack of fortified lines. Each attack is to be made in a column. The first are the grenadiers or volunteers; then a number of armed workmen, with shovels, fascines, woolsocks, lad-

Attack and Defence of Field Fortifications.

Attack and defence of villages.

on fire. Perhaps a secret entrance, or ladders, may be of use, and are to be applied if circumstances will permit. The defence of such a house may sometimes be kept up very long. Even if the enemy has penetrated one part, he may be again repulsed if not very strong, or if his succours do not arrive in time.

An estate, or a church-yard, which has been fortified, may always be advantageously attacked by guns; and after an opening has been made, it may be carried by assault. The defence of a fortified village requires more circumspection. All passages to it are to be kept possession of, and sufficient posts and patrols are sent out, to prevent a surprise. All works are to be occupied only by detachments; and the reserve must be near the principal work, or stationed at such a place, that it may easily afford succour to any part. As soon as an alarm is given, all the works are properly occupied, and succours sent if necessary. The side of attack is to be discovered if possible, and particularly strengthened; but other fronts are not to be neglected. To prevent the force from being too much dispersed, it will therefore always be advisable not to occupy too large a circumference, but rather to be content with the defence of a strong post by a concentrated force. The attack of a village is generally made in two or more parts, one being the real and the other a feigned attack. But before it is undertaken, every proper and necessary information respecting the works should be procured, either by spies, or by reconnoitring.

The infantry penetrates first, and are immediately followed by the cavalry. This attack is in every respect the same as that of camps, already explained.

The defence of a country town may sometimes be kept up for a considerable time. As soon as its defence is resolved upon, a general place of alarm is chosen, all the streets are ordered to be illuminated if the alarm is given at night, and no inhabitant is to appear at that time. The posts, guards, and sentinels, must be attentive, and patrols are also to be sent round the town. In the day-time, posts are placed before the gates at greater distances. No gates towards the country should be opened at night, until there has been a close examination and proper lights, lest the enemy should attempt a surprise; and never should more than one man be allowed to enter at a time. If necessary, the inhabitants are to be disarmed. The soldiers are to be quartered in such a manner, that each may soon repair to his post, and to such works as he has to defend.

To prevent the enemy from approaching secretly, the surrounding country is to be surveyed, and every thing that may favour his approach is to be levelled. The gates should be barricaded, and every one who goes out or enters must be known by an inhabitant, who must be made answerable for his conduct. No assemblages of people are allowed, and particularly near the gates. If the enemy advances to the attack, no fire is to be opened upon him till it can be done with effect. Should he penetrate at any part, a force must immediately be collected to oppose him, taking care always that a retreat be secured, even though a capitulation should be the consequence. The most advantageous mode of attack is by surprise, which is to be effected in the same way as the surprise of a fortress. The same applies to towns, and indeed to fortified places of all kinds.

When a town is set on fire, the inhabitants usually intreat or compel the commandant to surrender.

Should the enemy undertake a sortie, or if a gate can by any means be penetrated, it will hasten the surrendet of the town. In all cases, however, the retreat of the enemy is if possible to be cut off.

A most advantageous attack of such a town is made by tirailleurs, in the same manner as has been explained in the Section on the Attack of Permanent Fortifications.

Sketch of Carnot's Method of Defending Fortified Places.

From the account which we have now given of the attack and defence of fortified places, the reader must have observed, that when a fortress is regularly invested, however strong it may be, its fall after a certain period is considered as a matter of course. The maximum of that period we formerly stated at 90 days. In the actual state of things, however, it seldom exceeds the half of that, and even this is considered a good defence. In proof of these remarks, we subjoin the calculation which Vauban gives of the duration of a siege, according to Vauban.

We have already observed, that the application of such calculations to the operations of moral causes, may perhaps at first sight appear absurd. It is to be remembered, however, that from the superior force which the besiegers can always command, it is impossible that any place can hold out for an indefinite period. It seems reasonable, therefore, that certain laws should be established among nations with regard to the surrender of fortified places, in order to prevent the obstinacy of an individual being the cause of an unnecessary effusion of human blood. Such laws have accordingly been generally recognised, and those who persevere in their defence of a place, after it ought by these laws to surrender, are considered as having deprived themselves of the privileges usually granted to prisoners of war. A modern writer on fortification, M. now Count Carnot, has, however, advanced a very different doctrine. Reasoning on that fundamental principle of military discipline, that every soldier ought to die rather than give up his post, he maintains, that such calculations as we have detailed above, are generally false, and that, when they are true, they tend only to crush the spirits and paralyse the efforts of the defenders. He considers the courage and determined perseverance of the garrison as the strongest bulwark, and therefore condemns every thing that tends in the slightest degree to depress or extinguish these. Such reasoning, however, would scarcely be entitled to notice, and certainly would never contribute, in any essential degree,
cannot has proposed a new system of defence, against which he considers the present method of attack altogether inefficient. Admitting what, indeed, cannot be denied, that if the besiegers are permitted to proceed step by step, with their approaches and parallels, as in the ordinary way, the guns of the fortress will soon be silenced, and the fall of the place must follow; he sets out with showing how the progress of the enemy is to be retarded. This is principally to be done by irregular sorties, so contrived, that the sallying force may always be greater than the force to be attacked. The sallies commonly made in the present system of defence are too regular to be effectual. They are always made at the same points, where, of course, the enemy is always prepared to receive them; so that, before they can succeed in destroying any of the works, they must combat a superior force. But by contriving to have a great number of points from which sorties can be made, the garrison may have abundant opportunity of attacking the enemy inferior force, so as to insure success in destroying the works intended, without sustaining any considerable loss. By these, frequently repeated, the enemy's progress is retarded, his troops are harassed, and he is obliged to employ a much greater number in defending his workmen, as it is only by a very strong guard at every possible point of attack, that he can protect his entrenchments from the disastrous effects of these sorties. But even should he have men enough to form sufficient guards on every part of his works, by crowding great numbers into one place, he only exposes them to a more certain destruction, from the immense number of vertical fires (feux verticaux), which form the second, and indeed the principal part, of Carnot's method of defence. These consist of mortars of different calibres, elevated at an angle of about 45 degrees behind the parapet, and covered by blindages. In this way, the guns themselves, as well as the men who work them, are completely protected, both from the direct and ricochet fire of the enemy. When used, they are loaded with a charge sufficient to carry the shot to such a height, as that, by its descent, it shall acquire velocity enough to prove fatal to the person whom it may strike. Of the effect produced by these vertical fires, when substituted for the greater part of horizontal guns, in a garrison of an ordinary size and strength, Carnot gives the following calculation.

The vertical fires are supposed to commence only when the enemy opens his third parallel, as the distance previous to this would render their effects less certain. From this period till the opening of the breaches, the usual calculations allow 10 days; and the effects of the vertical fires during these 10 days may be found thus.

Supposing the third parallel to be 100 yards from the flanked angles of the bastion and of the ravelin, and the length of the exterior side of the polygon 300 yards, the field occupied by the besieging army will be nearly 36,000 square yards; but, in order to estimate the useful effect of the fire, call it 60,000 yards.

It is now necessary to ascertain how much of this space is actually covered by the bodies of the men who act as labourers and guards of the besiegers works. The number of these men is generally estimated at three-fourths of the garrison, a smaller proportion being found too weak for resisting the sallies of the besieged. Supposing then that the garrison consists only of 4000, the guard of the trenches will be at least 8000, that is, 800 men will be spread over the surface of the ground forming the avenues of the place; but these avenues, it has been shown, are contained within a space of 60,000 square yards, therefore the number of the besiegers occupying the avenues or passages, will be one-twentieth of the square yards, that is in the proportion of one man to 20 square yards.

Let it now be supposed that a man's body projected horizontally covers one square foot, and nine men will thus be required to cover completely a square yard.

But it has already been calculated that there is one man in every 20 yards of the space occupied by the besiegers, therefore the space actually covered by the bodies of the enemy's troops and workmen, will be the 180th of the whole; and, consequently, out of every 180 shots falling in an inclined or parabolic line with, in that space, one, in the course of a long continued fire, will strike the enemy. It is to be observed, however, that this is the minimum, or least possible effect to be expected from such a fire, because all the data on which the preceding estimate is founded, have been drawn on the most unfavourable suppositions. The enemy has been supposed equally distributed over all the space, instead of being very much concentrated, as they really are on the glacis, towards the capitals of the salient angles, to which the vertical fire may also be readily confined. A man's body, too, has been supposed to cover only one square foot when horizontally projected; but if he is working or marching, which must be the case with the greater part of the besiegers, it will occupy a much larger space; besides, as the line described by the shot is not perpendicular, but inclined, the surface presented to it by a man's body, must be double his horizontal projection. All these circumstances considered, it would not, perhaps, be too much to suppose that one ball in 50 takes effect; but to prevent every possible objection on this score, let it be supposed, as above, that one ball in 180 proves fatal to one of the besiegers.

Let it be supposed, in the next place, that there are mounted on the attacked front, six twelve-inch mortars, forming each of the bastions, and two on the ravelin, so situated as to fire along the capital of each. The mortars, as formerly observed, are protected from the direct fire of the enemy by the parapet, and from the ricochets by a shell-proof covering, having only one opening sufficient to allow the escape of the shot at an angle of 45°. The side towards the place may be open to prevent the collection of smoke, and surrounded with a small fosse to secure it from the shells that may fall near it.

To estimate the effect of each piece then, it is to be observed, that as the shell of a twelve-inch mortar weighs 150 pounds, the same weight of balls, each a quarter of a pound, may be fired with the same charge, that is, each mortar, at a single shot, will discharge 600 such balls, being 3600 from the whole. But it has been shown, that out of 180 balls, one may be supposed to strike the enemy; therefore at each discharge of the six mortars, twenty of the besiegers will be put hors de combat.

It remains now to inquire how many rounds may be fired in the space of 24 hours, the fire being continued during the night as well as the day. These, at a moderate calculation, may be rated at 100, which allows nearly a quarter of an hour to each round. But at every discharge 20 of the besiegers are disabled; therefore in 24 hours, 2000 men will be destroyed or rem
Advantages of the system in point of economy.

From the above calculation, Carnot concludes, that no fortified place, whatever be its size, if defended in this way, can be taken by any method of attack presently in use. Nor is the certain destruction of the besieging force the only advantage of this new method. Economy, both in men and money, is another and a powerful recommendation in favour of the system. The garrison is neither exposed to danger, nor harassed by a laborious defence. A few companies of artillerymen are alone requisite, who can carry on their operations without any danger from the enemy's fire, and without any interruption from dismounted guns, or broken carriages. The great bulk of the garrison have nothing to do but watch the most favourable moment for making a sortie; and by thus obliging the besiegers to keep strong guards on their works, they render the vertical fire more effective. It has already been shewn what execution may be done by six mortars alone; and from this it may easily be calculated what any greater number might effect in a given time. It is not necessary that all the mortars should be of the same size, nor that they should be all planted in the same places. They may be of various calibres, and mounted on different parts of the works, according to the distance of the besiegers. It is obvious, however, that, at a given expense, more execution may be done by such mortars, than by artillery of the common sort. As the charge is in general small, perhaps cast iron balls might be strong enough to resist the shock, without breaking, which would of course diminish the expense still more. But even though it were found that these did not answer, bars of iron, which are used for many other purposes during a siege, by being cut into pieces of about an inch in length, might be used instead of balls; and if the garrison were supplied with a great number of large mortars or swivels, even this expense might be saved by loading them with stones. The number of stones discharged from a single mortar at once would not be indeed above one-tenth of the iron balls; because stones, to produce the same effect, must be so many times greater. But if the number of mortars were ten times greater, the total effect would be the same.

Having stated some of the advantages of his system, Carnot proceeds to shew, that it is only by adopting it that the balance between the modern systems of attack and defence can be turned in favour of the latter. The duration of a siege, he observes, rarely ever extends to six or seven weeks, and, in most cases, does not exceed twenty-two or twenty-three days. Of these, fourteen are generally occupied in constructing the approaches; so that the actual attack on the place is reduced to eight or nine days. The cause of this very limited period of defence is to be ascribed, he thinks, partly to the impossibility, in the present system of defence, of mounting artillery, so as not to be very soon silenced, and partly to the want of such a method of firing as can reach the besiegers behind their intrenchments. Both of these desiderata are supplied by his method, which he then proceeds to vindicate from some objections that have been started against it. These objections are as follow:

1st. That the balls recommended are not large enough to produce the desired effect.

2d. That the besiegers would avoid the fall of the shot, by keeping out of their reach; and,

3d. That the method recommended would consume a great deal of iron.

In answer to the first objection, he observes, that there is nothing unreasonable in supposing that a square piece of iron, of the size of a pigeon's egg, should, in descending through 120 feet, acquire velocity sufficient to kill a man. But should this be questioned, he appeals to the example of the ancients, who with their slings, which carried to a much less distance than modern swivels, and with balls much lighter, easily killed or maimed their enemies.

To the second objection he replies, that it can only be worthy of refutation, when it has been shewn that a besieging army may take a place without approaching it. And,

On the third, he remarks, that for the very same reason a garrison should not use artillery of the common kind; because it will consume a great quantity of lead. But the force of the objection is still more completely removed, when it is remembered that stones may be substituted in the place of metal balls.

The ingenious author is not satisfied with replying to objections that have actually been made against his system; he also anticipates others that might be advanced. He observes in particular, that it would be impossible for the besiegers to approach the place under the protection of blindages, because it would be impossible for them to find either time or materials for the construction of such works; and even if they could, the slightest sortie from the garrison would throw them into confusion, and destroy in a moment the fruits of their long labour.

But it is not only before a breach has been made that this new system of defence can be employed. It is equally effectual in resisting an assault, provided there be an interior intrenchment between the rampart and the place, when a few mortars have been mounted, and reserved for the moment of the attack. At this moment, the garrison is to retire from the breach, and the mortars of the retrenchment are to open at once with a discharge of balls or stones. The consequence of this must be total destruction, or at least immense loss, to the breaching party. Should any of them in the mean time gain a footing on the rampart, they must be in great confusion, and may therefore be easily dislodged with the bayonet, the garrison taking care to attack them the moment the fire ceases.

Such is a short outline of the system of defence proposed by one who appears to have devoted the efforts of a powerful mind, and the labours of a long life, to the improvement of a science interesting above all others to his country, but which military men, in general, have been too ready to regard as incapable of further improvement. In comparing this system with what is still commonly practised, it is impossible to avoid being
FORTIFICATION.

Carnot's Method of Defence.

struck with the radical difference in the principles on which they are founded. In the old method, the garrison acts almost solely on the defensive; it waits the advance of the besiegers, and is obliged to sustain the heaviest shock after half its means of defence have been destroyed; but in Carnot's method, the garrison, by a combination of society and vertical fires, is constantly acting on the offensive. By the one it cuts off weak parties, and destroys their works, and by the other it assails the strongest force with a certainty of success unknown to every other species of artillery. In a word, it puts into the power of the defenders all the advantages that have been for so long a time exclusively possessed by the besiegers, both in offensive and defensive operations.

In enumerating the various kinds of projectiles that may be used in defending a place, Carnot also recommends common artillery in certain circumstances, but thinks they should not be fired through embrasures, at least if they are mounted on the faces. Instead of these he proposes temporary merlons, consisting of bags of earth, to be used till the enemy opens his ricochet batteries, after which the artillery is to be withdrawn. Grenades, he thinks, might also be used with great advantage, and even in some cases the manudalista and scorpon of the ancients. There is still another kind of artillery, however, which, from its singularity, merits attention. It was first suggested by M. Flachon de la Jonariere, and consists in discharging an immense quantity of water by means of pumps on the works erected by the enemy on the crest of the covert way. By this means Jonariere supposed that the earth would be so completely soaked, as to put a stop to their work. "It would not be difficult to conceive," says Carnot, "that this idea was every where turned into ridicule. It was however decreed by government, in 1785, to put the plan to the test of experiment, and that experiment, to the utter confusion of the sarcasm makers, completely succeeded. The sappers could no longer fill their baskets; the earth was converted into a liquid mud, which slipped from under them, and of which it was impossible to construct any intrenchment. Yet, notwithstanding all this, the experiment has never been followed up;—a proof that it is not always sufficient to have experience, reason, and even the good of the state on one's side—the inertia of indolence may resist all these. Perhaps an age or two hence, some extraordinary events may shew, that the idea is neither extravagant nor absurd." We should not be surprised if the sentiments which Carnot has expressed with regard to Jonarière's plan of defence, are hereafter found to be strictly applicable to his own.

As might be expected from what has been already stated, the present construction of fortifications is, in the opinion of Carnot, extremely defective. Of these defects he has given an enumeration, and has also illustrated them at considerable length.——They are as follows:

1st, There is no provision made for covering either the artillery, or the garrison on duty, from the fire of the enemy. In consequence of this, the guns of the fortress are generally dismounted in a few days.

2d, There is no interior work or entrenchment, so that whenever the besiegers make a successful assault, the place is in their power, and the inhabitants exposed to pillage.

3d, The communication between the different parts of the place and the outworks, is too difficult for the prompt execution of any necessary movement. As an improvement in this respect, Carnot proposes, that instead of a wall in the counterscarpe, there should be a gentle slope or glacis, from the covert way to the bottom of the fosse, so that if the besiegers should get possession of the former, the besieged might make an attack upon them at any point, where they had the greatest prospect of success. Should it be objected to this construction that it would enable the enemy to advance without interruption to the bottom of the enceinte, Carnot justly observes, that it is not advancing thither, but establishing themselves there, that is to be dreaded; and this they would not easily do without immense loss from the fire of the place.

4th, The covered way is not constructed so as to answer the purposes for which it is intended. These are, 1. To collect the force that may be sent to the assistance of the place. 2. To form the troops intended for a sortie. 3. To serve as advanced posts for preventing surprises. 4. To cover by its parapet the revetment of the works: And, 5. To furnish a second line of fire to the enceinte. On the first of these our author observes, that the covert way being hid by a palissade towards the field, it is a matter of great difficulty for the auxiliary troops to find out the point where they can enter it, and even after they have entered it, if they consist of cavalry or artillery, it is equally difficult to find admissione into the place. For the same reason it obstructs, rather than assists, a sortie, particularly if the sallying force consists of cavalry. As to preventing surprises, it is, in its present form, of very little use, as the besiegers can, in a few minutes, make their way over the palissade, by means of their fascines, and that too with scarcely any noise. In covering the revetment of the works, it might be useful, if its parapet were higher than the revetment; but it is well known that, in the greater part of modern fortifications, this is not the case; and, with regard to its affording an additional line of fire, it is obvious that, as the besiegers are always covered by a parapet, the raising fire which the covered way affords can be of little value. Many of these disadvantages would be avoided, by substituting a glacis for a revetted counterscarpe, as already described.

5th, In the present construction of fortified places, the ravelin does not completely cover the shoulders of the bastion, so that the enemy can reach them with his fire through the openings of the tenaille.

6th, The escarpe is too much exposed.

7th, There is no means of having a fire directed along the capitals of the salients, on which the enemy's approaches are generally constructed.

8th, The fall of the revetment at the time of the breach, generally drags with it the whole of the parapet, which greatly facilitates the assault of the enemy. This might be remedied by having a way of rounds, though that too has its inconveniences.

9th, The masonry of the works, on account of their talud or slope, is easily worn down by the action of the weather.

10th, The place, in general, is not furnished with sufficient souterrains for protecting the men and the ammunition.

11th, The present system of defence requires a much greater quantity of wood than can in most cases be procured: And,

12th, It exposes the soldiers to severe and incessant labour, without the possibility of their obtaining necessary repose.

The great length to which this article has already
extended, prevents us entering so largely, as we otherwise have done, on the system which we have now endeavoured to sketch. From the preceding observations, however, our readers will readily perceive, that the work is not unworthy of its distinguished author, and that the principle which it unfolds is peculiarly deserving the attention of engineers.

See MILITARY ARCHITECTURE for the subject of Castelation, and other topics connected with the preceding article.

FORTS, VITRIFIED. The appellation Vitrified Forts, has been given to certain melted or vitrified masses of stone, which were discovered on the tops of some hills in the north of Scotland, about the year 1775 or 1774, by Mr Williams, a mineral surveyor, who published an account of them in the year 1777. For a considerable time, they engaged the attention of some of the first literary characters, and gave exercise to the ingenuity of antiquarians. Various conjectures and theories were announced; and some went so far as to conclude, that nothing short of volcanic fire had produced the vitrifications. Whether it has been owing to an idea, that their origin was involved in impenetrable obscurity, or that there seemed to be no prospect of the learned world coming to an agreement of opinion, it is certain, that a very long time has elapsed since this field of research has been abandoned, and curiosity apparently been asleep. Happily, the spirit of inquiry is now more widely diffused, and less easily damped; and we shall consider ourselves fortunate, if the brief notices in the present article shall lead to a more general and accurate examination of the appearances under review, than has hitherto been bestowed upon them. Mr Tytler (the late Lord Woodhouselee) has very justly remarked, in a memoir written on this subject about thirty years ago, and published in the Transactions of the Royal Society of Edinburgh, "how curious it is, that the same appearances to different observers, lead to the most opposite opinions and conclusions!" This clashing of opinions may sometimes be owing to the different degrees of attention which have been bestowed on the facts, and their relative connections. It sometimes happens too, when a person has formed a theory, that he is very apt to view every thing with an eye, which sees only what accords with his own fancy, to the entire exclusion of the views of others. But circumstances of importance often escape the most accurate observers, and lie concealed till accident leads to their discovery, or till unbiassed observers remove the exaggerations, occasioned by fondness for a new discovery, or by attachment to a new theory.

It appears to us that, whatever may have been the cause which discovered to the inhabitants of the country the vitrifiable nature of the stones, of which we find these strata in question composed, or suggested the application (if ever it was made) of this discovery to any useful purpose, some confusion has arisen in the attempts to account for the present appearance of the vitrified masses, from the want of means to trace their first origin. It has fallen to our lot to discover such means; and having been so fortunate, we have some hope of being able to reconcile many opinions which at present seem to be very opposite, and to open a path which may lead to the truth. For this purpose, we shall begin by describing the facts which presented themselves to our view, while examining the top of the hill of Dun Creich in Sutherlandshire, where, we think, the true origin of the vitrifications, which have occasioned so much speculation, has been found. We trust that it will appear evident, that making signals by means of fire has occasioned not only the appearances in Dun Creich, but those on many other hills, and has probably been the origin of this singular method of cementing stones, if indeed it was ever resorted to for purposes of architecture.

Near Creich, in the county of Sutherland, a ridge projects into the Frith of Dornoch, terminating in an abrupt precipitous hill. This ridge lies nearly east and west; and from the summit there is an extensive view of the sea, and the country towards the east; and of the valley, containing the Dornoch Frith towards the west. The access to the top is by no means easy, even where it is most practicable. Round the edge of the summit there is a rampart of loose stones, marked on the plan (Plate PLATE CCLX. Fig. 1.) by the letter B, is another rampart of loose stones, which is probably the remains of a structure intended for the same use, but which has been exchanged for the more substantial and convenient building within. C is a wall, which has been filled up. There is a very good spring of water on the outside of the rampart, on the south side of the hill. D marks a line, on which there is a mass of stones bearing abundantly the marks of fire, and which we traced across the whole summit. The surface of the hill within the outer rampart is uneven and rocky; and that part of it which is crossed by the vitrified mass, is rather lower than the eastern portion.

The line D being the only one which is vitrified, no marks of fire appearing any where else, is a striking and important fact. This line extends from A to B on the sketch (Fig.3), passing over the top of the hill, and Fig. 3. in the only direction in which a range of signals could be made, so as to be distinctly seen further up the country. To be satisfied of the reason why the signal fires should be kindled on, or beside a heap of stones, we have only to imagine a gale of wind to have arisen when a fire was kindled on the bare ground. The fuel would be blown about and dispersed, to the great annoyance of those who attended. The plan for obviating the inconvenience thus occasioned, which would occur most naturally and readily, would be to raise a heap of stones, on either side of which the fuel might be placed to windward. To account for a large extent of vitrified matter, such as that along the line D, it is only necessary to allow the inhabitants of the country to have had a system of signals. A fire at one end, might denote something different from a fire at the other, or in any intermediate part. On some occasions, two or more fires might be necessary, and sometimes a fire along the whole line.

It is evident, that the people who formed the structure on Dun Creich, had no idea of applying fire for the purpose of strengthening the ramparts, and had not even taken the hint afforded them by the effects of the signal fires. Hence we consider the appearances at this place as demonstrative of the fact, that the vitrifications have been occasioned by the lighting of signal fires, to warn the inhabitants of the approach of an enemy, or to convey the orders of a chieftain to his dependants. It appears too, that such signals have been common after the use of lime mortar was known, since we find on this hill the remains of a building constructed...
with it. This may have served the double purpose of 
a watch tower, and the habitation of the people who 
had charge of the station. At the head of the valley 
are the remains of an old castle, with which the station 
was probably connected. While on the top of Dun 
Creich, it occurred to us, that marks of fire would be 
found on a hill, which obstructed the view of Dun 
Creich from Strath Carron, a valley which branches 
from that of the Dornoch Firth. We went to the spot, 
and found several masses of melted stones. A few miles 
up Strath Carron, where a stone rock occupies an angle 
formed by the river Carron and a tributary stream, are 
the remains of a fort, built in the circular form of the 
Duns, (or Danish, or Pictish forts, as they have been 
called,) with distinct traces of ditches and earthen ramp-
parts in front. With this also, the signal station of 
Dun Creich may have been connected.

We believe that nothing similar to Dun Creich, or 
other vitrified forts, has been observed farther to the 
northward; though it is probable something of the sort 
may exist at the head of other Firths. The next we shall 
take notice of is the first we meet with to the south-
ward, and is situated at the head of the Cromarty Firth. 
The name of the hill is Knock Farril, and it is one of 
those which arrested the attention of Mr Williams. It 
is about two miles from the town of Dingwall, in the 
county of Ross, and forms part of a double ridge, which 
bounds the valley of Strathpeffer on the south, and 
separates it from the valley of the river Conon. The 
ascend from the east and west ends is comparatively 
easy, but the sides of the hill are very steep. From 
the summit on the top there is an extensive view of the Firth of 
Cromarty, and of the adjacent country; and the hill of 
Craig Phadrick near Inverness, on which there are vi-
trifications which have been described by Mr Tyler, 
is distinctly seen. The flat area on the top is a good 
deal inclined towards the west; its length being about 
135 yards, and its medium breadth about 45. Round 
the area, and close to the edge of the hill, we find 
masses composed of stones cemented together by melt-
ed matter, irregular in their positions and size; and ex-
tending at each end about 50 yards from the area. 
The vitrification is every where superficial, extend-
ing but a very little way among the stones. There 
is a considerable quantity of rubbish seen in the cuts 
which Mr Williams caused to be made across the 
area in different places. This rubbish appears to have 
been collected for the purpose of extending or forming 
the area on the top; and it would seem that much la-
bour had been bestowed in accomplishing in this man-
ner what might, apparently, have been effected more 
easily by cutting down part of the summit. On the plan 
(Plate CCLX. Fig. 2), A, marks the cuts made by Mr 
Williams; B what seems to be the vestiges of a hut; 
and C the remains of a well, or rather a tank for hold-
ing rain water; for there is no appearance of spring 
water issuing from any part of the hill. The area mea-
sures nearly an English acre. This station may have 
been chosen to give warning of the approach of ships 
up the Firth of Cromarty, and was probably the signal-
post of the castle of Dingwall, formerly the residence 
of the Earls of Ross.

To account for the vitrification appearing all round 
the area, we have only to refer to our supposition of a 
system of signals, and the shifting of the wind render-
ing it necessary to change the side on which the fires 
were to be lighted. The vitrified masses appear in 
many instances to have been displaced; and one fact 
occurred to our notice which ascertains this displacement 

FORTS, VITRIFIED.

beyond a doubt. On searching below a mass, the vitrified 
side of which was considerably inclined, we observed 
some melted matter that had run down and consolidated 
in the form of stalactites. Had this mass been in its or-
iginal position, these would have been perpendicular; but 
they were at right angles to the inclined vitrified surface. 
Many fortuitous circumstances may have contributed 
to produce the present irregular appearances. It can-
not be doubted that the rampart was originally formed 
with as much regularity as the nature of the materials 
would allow, both in order to render it more durable, 
and to make it serve the purposes of defence. For we 
must believe, that so important a station as one for 
signals, was rendered sufficiently strong to resist the 
attacks of an enemy. We do not, however, consider 
that any appearance on Knock Farril indicates the fu-
sibility of the stones having been used for consolidating 
the ramparts. Dr Anderson was mistaken when he stated, 
in the 6th vol. of the Archaeology, that the vitrifications 
are to be seen only on the outside of the ramparts of 
Knock Farril. He mentions, however, the fact, that 
on the hill called Top of Noth, in Aberdeenshire, the 
vitrification is only on the inside; which is a very sa-
tisfactory confirmation of the idea that it has been pro-
duced by signal fires. Had the outside of the rampart 
on Top of Noth been vitrified, we might have been 
warranted in concluding that fire had been used to 
 strenghten it. Had the inside been vitrified with this 
view, it is impossible to conceive that no attempt was 
made to cement the outside also; since in every struc-
ture for defence, however rude, we find the strongest, 
and not, as in this instance, the weakest, part opposed 
to the approach of an enemy. On some hills, places 
apparently intended for defence have been found, 
where there are no appearances of vitrification. In 
such instances it is probable that the stones will be 
found not to be of an easily fusible nature; if in reality, 
no vitrification can be found, on accurate search being 
made. This last remark is occasioned by the discovery 
of a mass of vitrified stones on the hill of Dun Jardil, 
one of the stations along the great chain of lakes, which 
escaped the notice of Mr Tyler, but was found by Mr 
Nimmo, civil engineer, and late rector of the academy 
at Inverness.

The following considerations seem to support the 
idea of such high situations being chosen expressly for 
signal stations. Such hills only, as command an ex-
tensive view of the sea, or adjacent country, have been 
selected.

Each hill is in sight of one or more similar stations, 
as far as has yet been observed, with the exception of 
Dun Creich, which seems to have been devoted exclu-
sively to the use of the extensive valley in which it is 
placed, though hereafter others may be discovered to 
be connected with it.

There is a regular chain from Knock Farril and 
Craig Phadrick, along the great valley of Lochness to 
the west coast; and others are in sight towards the 
est. So that, on the appearance of an enemy on ei-
ther side of the island, the whole country from coast 
to coast could be informed, probably within the short 
space of an hour.

Such is the situation of vitrified forts exclusively; 
for they are not seen in any but commanding situa-
tions; while many spots more convenient, and better 
adapted in every respect for defence, are often to be 
found in their vicinity, or at no great distance.

In the statistical account of the parishes of Boleskine 
and Abertarf, the hill of Dunardile, or Dun Jardil, men-
tioned by Mr Tytler, is noticed; and it is added, "that a similar tower is in the same direction, contiguous to the house of Invergarry; and that the tradition of the country is, that those hills were watch-towers for giving signals upon the approach of an enemy by large fires." It is about seventeen years since the writer of this article suggested to several persons whom he accompanied in their visits to Knock Farril, which is near his country residence, the idea of vitrified forts having been signal stations; but this he believed was not new, though he had not before seen or heard it stated. The opinions which were at that time entertained, were, that fire had been used for the purpose of cementing the walls, by fusing the materials of which they were composed; and that the vitrifications had been caused, not in the erection, but in the destruction of the buildings, of which we now see only the ruins.

The first of these opinions, started by Mr Williams, was supported by Dr Anderson; and if we consider the possibility of forming walls which shall be cemented by the fusion of a part of the materials, there appears no reason whatever to doubt it. But it is not whether a wall can or cannot be constructed of fusible materials, which is the question; but whether appearances which now present themselves justify the assumption that they had such an origin. We have already shown that the people, who had seen the possibility of heat being applied successfully to cement a wall on the hill of Dun Creich, had not availed themselves of what must have been long apparent to them. No wall, or part of a wall, of a uniform thickness, has ever been vitrified on both sides, or throughout, so as to indicate a regular mode of procedure in its formation. We find, indeed, a regularity in the form and manner in which the ramparts are laid down, and which has been guided by the shape of the hills: but nothing else than irregularity in the mass of which they are formed. We speak of all those we have seen, and of a variety of descriptions which we have read. We often find masses of melted matter of a breadth far exceeding what can be imagined the limits of a wall; and we find them, too, as on Craig Phadrick, on the brink of immense precipices, where no wall was necessary. When a breach of the vitrified wall of Dun Creich 40 feet is mentioned, it instantly occurs as being very likely that the labour of constructing such a wall was thrown away, since one half the thickness is far beyond the strength necessary for a rampart. There is little difficulty in conceiving how signal fires, kindled sometimes in one place, sometimes in another, and varying in magnitude as occasion required, might spread over a surface of forty feet. The shifting of the wind, and the violence with which it blows on the tops of such hills, was sufficient to put those who had the charge of making signals, on some contrivance to prevent the wood from being def. serted, and themselves from being annoyed; and thus the ramparts of loose stones which they had raised to defend themselves from being surprised, may have become stronger without their having had any intention of making them so. It is Nevertheless by no means unlikely, that in some cases, the fusible nature of the stones might have been taken advantage of; but there is nothing which we have been able to discover to justify the idea that a regular method for raising walls and cementing them by fire, was ever in use. On the hill of Dun Jardi, Mr Tytler could discover no marks of vitrification; yet such marks were discovered by Mr Nimmio, on the only part of the hill where signals could be made, so as to connect the great chain of posts extending from coast to coast; and along this chain it has been found necessary to make use of hills on both sides of the valley, in order to complete the communication. 

Here, then, is another instance in which the fusibility of the stones has not suggested the idea of strengthening walls by means of fire. But we have said enough on this part of our subject.

Mr Tytler has accounted for the present irregular distribution of the vitrified matter, in a more simple and in a more ingenious manner than Mr Williams and Dr Anderson. He supposes that the cause of the vitrification is to be found, not in the mode of constructing, but in the means employed to demolish the ramparts; which, according to his theory, were originally built with stones intermixed with wood, thus presenting to an enemy a defence easily destructible by the application of fire.

It is difficult to find any reason why such structures should be made, at a time when the effects of fire upon wood must have been as well known as at present. At a period when it was the only fuel made use of or known, little ingenuity was necessary for discovering that any structure made wholly or partly of wood could easily be destroyed by fire; and the people must have been very silly indeed, who were incapable of foreseeing that the ingenuity of their enemies might enable them to find out so simple, and, to such fortifications as Mr Tytler has constructed for them, so formidable a weapon. It was necessary that such a structure should be only once destroyed by fire, to prove to the inhabitants the frail nature of their defence. And if their enemies were expelled, it is natural to suppose that they would have renewed their forts, and constructed them in a different manner, so as to resist the attacks of fire. But nothing has been found indicating any renewal of the fortifications. That a rampart may be con-structed of stones and wood, which shall not be liable to destruction by fire, and that such ramparts have been formed, there is no reason to doubt. But, in the case before us, it is necessary that the quantity of wood should have been so great, as to admit of fire being set to it easily. If Mr Tytler's conjecture be right, we ought to find the melted matter pervading indiscriminately every part of the rubbish. But the vitrification is only superficial, extending but a very little way among the stones.

These few considerations, together with what we have already stated in favour of another, has induced us to reject Mr Tytler's hypothesis. On the whole, we are of opinion, that the antiquity of these structures is by no means so great as that which has been attributed to them; and that they have served as beacons to castles in their vicinity, the remains of which are, in almost every instance, to be found. We allow that, while these hills were chosen for signal stations, they were also used as places of defence. And, indeed, it would have been strange if posts of so much importance had been left without the means of resistance. All have agreed that they were places of more or less strength, though perhaps such lofty and exposed situations were not well chosen for protracted warfare. Had they been merely places of retreat, an invading enemy would certainly overlook them, as he could overrun and pillage the country without the possibility of his being annoyed from them; or if there was any risk of his progress being inter-
The situation of the hills would render it easy for a small party to coope up the garrison. But as an enemy would always endeavour to approach unseen, and to prevent the country from being alarmed, these stations would undoubtedly be objects of attack; and hence we should be warranted in supposing that they were, to a certain extent, fortified, even were the appearance of ramparts less unequivocal.

Nor are we disposed to deny, that, in some instances, the fusibility of the stones may have been made use of to assist in strengthening the ramparts; though nothing has yet occurred to our observation, or in the course of our reading, which we consider as carrying with it any thing like demonstration, or even the suggestion of any such method of constructing them.

Our object, in this article, being chiefly to excite curiosity, and to induce such of our readers as may have an opportunity of visiting these curious remains, to apply, on the spot, the different hypotheses which have been stated, and to favour the public, through some communication of the result of their observations, we shall now proceed to point out the situations of some of the most remarkable vitrified forts in various parts of Scotland, besides those already mentioned.

In Kirkcudbrightshire, about half a mile S. E. from the church of Ancroft, is a steep rocky hill about 200 feet high, which has been fortified on the most accessible places by a double fosse. On the summit, the following appearances present themselves, as described by the Rev. Hugh Gordon. "The top, which forms a level area, 30 paces long and 20 broad, is nearly surrounded with an irregular ridge of loose stones, intermixed with vast quantities of vitrified matter. The stones, consisting of the common blue schistus of the country, have been softened, twisted, and partly fused by the fire. These heaps of loose stones and vitrified matter are scattered irregularly over the top of the fort, and exhibit no appearance of having ever formed a continued wall. The vitrification is only partial and superficial, and seems to have been the accidental effect of large fires kindled on these high rocks, either for some domestic purpose, or for signal to alarm the country on the approach of an enemy. It was formerly believed that these vitrified forts were peculiar to that part of the island which is north of the Firth. But besides the one described above, there are two others in the country, and they all command a very extensive prospect of the sea."

In the island of Bute, in the parish of Kingarth, there is a vitrified fort; and in Cantyre, at the entrance of the bay of Carradale, on a small island, vitrified masses enclose about a rood of ground. We believe that some others have been observed in Argyllshire, particularly one on the hill of Dunseighe, which commands the entrance of Loch Tarbert. On the same hill, ramparts are seen constructed with dry stones, without any vitrification.

In Perthshire, the hill called Barryhill, in the parish of Meigle, seems to have been fortified with particular care. Dr Playfair thus describes it: "Its summit was levelled into an area 180 feet long, and 72 broad. Around the area, a mound of earth was raised from 6 to 8 feet high, and 10 to 12 broad at top. On this mound a wall of freestone was built, without any cement whatever. The foundation of the wall was composed of rough granite, and still remains. It is of the same breadth with the summit of the mound; but the height of the wall cannot be known. Gordon's estimate of it is very erroneous. Among the ruins there are several pieces of vitrified stone; but these vitrifications must have been accidental, as they are few and inconsiderable. Along the west and north borders of the area, are barracks or huts of dry stone, and sufficiently sheltered by the mound and wall; but no structures of this sort can be traced in the south part of the area. As the north and west sides of the hill are steep, and of difficult access, there was no need of an outer ditch in these quarters; but towards the south and east, where the hill gently slopes, there is a ditch 10 feet broad, and 12 to 16 feet below the foundation of the wall. At the S. E. extremity of the fort, a narrow bridge was raised over the ditch, 18 feet long, and 2 broad, except towards each end, where the breadth was increased. It was composed of stones, laid together without much art, and vitrified above, below, and on both sides, so that the whole mass was firmly cemented. That an opening was left below, after the process was finished, is doubtful. On the upper part of the bridge, a stratum of gravel was laid, to render the passage smooth and easy. This is the sole part of the fort intentionally vitrified. A few yards distant from the ditch, there is an outer wall, the foundation of which is about eight feet lower than the summit of the mound. The approach to the fort is from the north-east, along the verge of a precipice; and the entrance was secured by a bulwark of stone, the ruins of which are extant. There is no vestige of a well within the fort; but, westward, between the base of the mound and the precipice, there was a deep pond or lake, recently filled up by the tenants in that neighbourhood. About a quarter of a mile eastward, on the declivity of the hill, there are some remains of another oval fort, of less extent than the preceding, consisting of a strong wall and ditch. Tradition says that there was a subterraneous communication between these forts, which is not improbable."

We could have wished that more particular attention had been given to what is denominated a bridge in the foregoing description. From the circumstance of this vitrified mass crossing the ditch, Dr Playfair is satisfied that it must have been used as a bridge. He afterwards decidedly says that the approach to the fort was on the north-east side, while this bridge is at the south-east extremity. We are inclined to think, that, at this side, the south-east, was found the most convenient spot for making signals, and that the vitrified mass was raised, in order to allow of a fire being kindled on either side, according to the direction of the wind. The plausibility of this conjecture, we must leave to the decision of future observers.

From a hill called Laws, near the village of Drum-

The vitrifications on the hill called Top of Noth, have already been noticed; on account of their being found only on the inside of the ramparts, a fact confirmed by several authorities. The following description we met with accidentally in a MS. the writer of which appears to have been Mr. Leith of Whitecraigo. "The summit, on all sides, presents to a person who ap-
proaches it, a sloping mound, or pile of loose stones, of different sizes and shapes, few of them larger than a man may lift with both hands, though some few are ten times that bulk. When you get on the top of this mound, or enter by an opening in the east end of it, you discover that it does not consist of a heap of such stones, but as to make a large cairn, but that there is an open area of grass ground in the middle, which may be about 60 yards long, by 23 wide. The mound of stones which surrounds this space has, on the inside, the appearance of a thick strong wall that had for a long time been in ruins. The height of these ruins above the inner area is pretty uniform, and may be from 9 to 12 feet. A slight inspection discovers, that what has the appearance of a ruined wall, has never been connected together by any cement, as nothing of that sort can be discovered where it might most probably be found. But, at the same time, you perceive that very large masses have been formed by the union of smaller stones fused by the force of fire in various degrees.

In the same county is the hill of Dun o’Deer, in the vale of Garioch, on which there are also vitrifications; and, as on Dun Creich, the remains of a building constructed with lime mortar. This tower is of larger dimensions, and of greater strength, than that on Dun Creich, being 60 feet square, and the walls about 12 feet in thickness. Hence it appears to have served the double purpose of a watch-tower and a stronghold. This tower is evidently of more modern date than the vitrifications, part of which have been used in its construction. This circumstance, however, does not militate against the supposition, that the hill was used as a signal-station after the tower was built.

About four miles east from Forfar, is the castle-hill of Finnhaven, the vitrifications on which have led Dr. Anderson to compare them to the effects of the fire in a limekiln; and he represents them as having been produced by the irregularity of the weather, the wind blowing sometimes hard, sometimes gently. This is exactly what we suppose to have been the cause of the vitrifications, while we assign a particular purpose to the fire.

The walls in some parts of this fort have been laid bare, so as to appear at least ten feet high. We have no perfect description of the vitrification. Dr. Anderson describes it as appearing here and there in horizontal, or nearly horizontal streaks; but it is evident, that the wall had been built previously to the application of fire, in whatever way that may have been made. The stones are in courses, and banded, as we have been informed by the Rev. Dr. Jamieson, to whom we are chiefly indebted for what we state respecting this fort, and the stones have been very unequally and irregularly affected by the fire, and many of them not at all. Seven or eight varieties of stone appear to have been made use of. Had there been an intention to vitrify this wall, the most fusible stones would appear to have been selected; but instead of this, they have been placed in the wall indiscriminately with others. We have already remarked, that much pains seem, in some instances, to have been taken to fill up irregularities in the ground, so as to form a level area on the summit. Our information respecting this fort is not so clear as to enable us to determine whether the unusual height of the wall can be accounted for in this way. For defending a fort from within, a rampart of less height would have been sufficient. There are several cross walls on this hill, and the vestiges of outworks; and altogether it seems to offer much satisfaction on a careful examination. We regret, that our information, in regard to some of its peculiarities, came too late to enable us to visit the castle-hill of Finnhaven, before it was necessary to send this article to the press. It is said, that between this hill and that of Laws, already noticed, there is another fort, which completes the communication over a very wide extent of country. By keeping in view the isles, that signals by fire have been in use at the period when these fortifications were constructed; and looking around from the summit of the hills on which they have been placed, for hills similar in situation and shape, particularly at the entrances of valleys, or on ridges which interrupt the view; many vitrified forts will, we confidently expect, be discovered, and communications far more extensive than any hitherto observed may be traced. As the repulsion of foreign invasion was an object of interest to the country at large, hostile tribes and clans would naturally unite for the common defence; and, as their Scandinavian neighbours were in the habit of frequently molesting them, no plan for alarming the country with the utmost celerity appears so natural, or so effectual, as the lighting of fires.

A few miles from Fort-William, in the parish of Killmore, is the hill of Dunhairbigall, the summit of which is surrounded by a vitrified mass of stones. This hill commands a view of a great part of Mamore, and the whole of Glen Nevis. It is extremely probable, that this was the signal station of the ancient castle of Inverlochy. In this opinion the writer of this article was confirmed by Dr. M’Knight, who visited this hill, and who has mentioned his being struck with the probability of the conjecture, in the account he has given of Ben Nevis in the Memoirs of the Wernerian Natural History Society.

In the valley of the Beauly river, in Inverness-shire, about two miles north-west of the church of Killarity, is a vitrified fort, called Dun Thomann. It is circular, and about thirty yards in diameter.

The latest writer on the subject of our article is Dr. M’Culloch, who states his opinion in a memoir, published in the Transactions of the London Geological Society. He adopts the opinion of vitrified forts having been constructed as places of defence, by cementing the walls by means of fire; and rejects, in a peremptory manner, the opinion which we have attempted to defend, viz. that the origin of the vitrifications is to be found in the practice, universally employed by our ancestors, of alarming the country, when threatened by invasion, by fires lighted on conspicuous situations.

Dr. M’Culloch has guessed, by pacing, the dimensions of the ground plan of the vitrifications on the hill of Dun Mac Niolkloch, supposed to have been part of the ruins of Bereognium. He acknowledges, that a great part was concealed by being covered with sod, which he had no means of removing; yet he has given a plan of an extensive and regular set of inclosures. He has not favoured us with the shape of the summit, on which the position of the vitrified masses observed elsewhere always depends; but, from the shading of his plan, we may presume, that the inclosures stand on different elevations, and that those elevations command a view of different portions of country. It is stated, that the portion of ground inclosed is in length about 200 yards; whereas on the plan two separate inclosures are marked, one 56 paces long, and the other 37. One side of the latter appears to be
FORTS, VITRIFIED.

528

prolonged, so as to reach the edge of the hill at both sides. There is a third enclosure, 30 paces long. The want of a vertical section, or a drawing of the hill, prevents us from judging of the extent of Dr M'Culloch's title to set aside the idea of signal fires having been the cause of the vitrifications. The facility with which our author makes room for his own opinions, may be seen in the following sentence: "The supporters of this opinion have asserted, that they (the forts) always occupy the highest elevation; and that many of them are so placed as to be visible from each other. This is not true." The vitrified forts have never been asserted to occupy the highest elevation, and we cannot discover where Dr M'Culloch could find such an assertion to have been made. We do not remember an instance, in which there is not much higher ground immediately contiguous to the hills on which the vitrifications are found. It has been asserted by others, as well as by ourselves, that they are placed in commanding situations, from which an extensive view of the sea, or inland districts, can be seen. But this is very different from the highest elevation. That many of them are so placed as to be visible from each other, is known from the testimony of several writers, and is consistent with our own observation.

The rock of which the hill in question is formed is limestone; and Dr M'Culloch very properly infers, that the stone of the hill was rejected, on account of the effects of fire upon it, and that other stones were, therefore, collected in the vicinity. He supposes, that a trap breccia, found in situ about half a mile from the hill, was chiefly made use of, on account of its being fusible. Yet he states, that only the foundation of the wall is cemented together by melted matter. The masses of this rock are said to be rare on the plain near the hill; but it cannot be inferred from this, that they were not found in sufficient plenty at the time the rampart was constructed. The building of the rampart most probably occasioned the present scarcity of stones of this kind on the plain. But this is comparatively unimportant, since we have vestiges, in various places, which demonstrate the great labour which the ancient inhabitants of the country bestowed in collecting stones of particular sizes and shapes to suit their purposes. The vitrification extending, according to Dr M'Culloch, "in no case more than a foot or two from the foundation," does not, in our opinion, exhibit any sign of intention to construct a vitrified wall; and the effects of the fire appearing, in this instance, to diminish upwards, is precisely what we should expect to be the consequence of lighting signal fires against the rampart in the manner we have supposed. The reason why the pudding-stone is the prevailing material, appears in its being more easily broken into pieces of a convenient size than any other stone, and more easily quarried (if quarrying was necessary) than the hard primitive rocks.

From what we can collect out of this description, we are inclined to think it possible that a rampart of loose stones has been constructed on the vitrified mass, which is described as the foundation. Should this conjecture prove correct, it will be an additional proof that the fusibility of the materials has not always been made use of for the purpose of cementing them. Indeed Dr M'Culloch comes nearly to the same conclusion, as he has found it necessary to state the following hypothesis, which appears to us a very lame apology for builders neglecting their work; at all events, Dr M'Culloch has satisfied us, that the art of building walls, by means of fire, was not, in the present case, sufficiently perfect to raise a structure higher than a foot or two. "The imperfect usage of the upper parts, may be easily conceived to have arisen from a partial neglect of the fire after the wall had nearly attained its requisite height; nor is there any reason why it should not have been increased in height, by the addition of cold stones, after a firm foundation had been obtained." We do not see why a foundation of vitrified stones should be firmer than the solid limestone rock, on which they are placed. Dr M'Culloch observes, that the effects on the stones appear to have been produced by repeated applications of fire; an observation which accords exactly with the supposition of signal fires. We cannot discover, along with our author, any analogy between the appearances we have been considering, and the method employed to bake mud walls employed in Hindustan. Melting and baking we consider as very different things. In regard to the plan which has been supposed to have been followed in constructing vitrified walls, and which is approved by our author, we have only to observe, that the great heat necessary to fuse the stones, could not possibly be produced between two walls built of solids, or any thing else which would prevent a proper current of air passing through the fuel. To us the analogy to the glazed wall of Gatacre House in Shropshire, appears equally remote.

We hope, by the time we come to the article Vitrified Forts, that we shall have it in our power to throw some additional light on this obscure subject. Our remarks in this article, particularly those on Dr M'Culloch's memoir, shew how difficult it is to arrive at any settled opinion at present; though to us it appears evident that, to whatever use the fusibility of some stones may have been afterwards applied, the lighting of signal fires has caused the vitrifications at least in some instances; and, if not in all, that it has afforded the hint from which the idea of cementing stones by means of their fusibility has been derived. If it be really the fact, that walls were built in this manner, it is remarkable that no trace is left by which we can determine the method which was followed in their construction. The only data we possess on which our arguments in favour of this mode of building can be founded, are, the presence of great varieties of stones, a few of which are fusible at a high temperature, and of charcoal, which indicates the nature of the combustible materials. It is evident that the hills on which these remains have been discovered have been fortified with more or less care, and to a greater or less extent; and the question that remains is simply, What has been the purpose to which the fire, which fused the stones, was applied?—Was it applied to strengthen the walls by the builders; to destroy them by an enemy; or, have the vitrifications been the accidental effects of signal fires; or can we trace their origin to all of these?

FORTUNATE ISLANDS. See Canary Isles.

FOSSILS. See Mineralogy and Petrification.

FOSTAT. See Cairo, p. 214.
FOU LOH, an island in the Atlantic Ocean, connected with Zetland, from which it is distant about 20 miles west. It is situated in North Latitude 60° 44', and West Longitude 1° 43'. It is about three miles long, and one mile broad, chiefly formed of very high ground, and presenting to the ocean several precipices from 800 to 900 feet in height. There is one landing-place, which can be taken in calm weather only. During a storm, all is foam and spray, and the island is then inaccessible. The rocks are gnarled and mica slate, supporting horizontal beds of sandstone, slate, clay, and clay-ironstone. In the cliffs of sandstone, innumerable multitudes of sea-fowl hatch their young. When approached in a boat, in the breeding season, if any noise is made, the old birds leave their nests in such numbers as to darken the air. Here the different kinds of gulls of the world, and here also the storm-finch (Procellaria pelagicus) breeds. On the hills, the Skua gull may be found; and in the corn-fields of this remote island, the voice of the land-rail proclaims summer.

The inhabitants, which do not amount to 200 souls, chiefly support themselves by fishing. They occupy about 60 marks of land, which they cultivate with the spade, and rear a few horses, sheep, hogs, and poultry. The rocks, in summer, yield the natives a rich supply of eggs and feathers. In order to procure these, they run the greatest risks among the rocks, climbing by the assistance of a rope among the most frightful precipices.

As may be expected, many of these adventurous natives meet with an untimely death. This, to the relatives, while a subject of grief, is likewise matter of exultation, as the children will often be heard to boast that they are the descendants of those who have gone afore, or of those who have perished among the rocks.

Several places along the shore were pointed out to the writer of this article, where these melancholy events had taken place.

This island is seen in clear weather from the Orkneys, and hence is supposed, with great probability, to have been the Ultima Thule of Tacitus.

FOURENTH, Comma-redundant Minor (14), in Music, is an interval whose ratio is \(\frac{5}{18} = 1131 \Sigma + 22 f + 98 m\), and its log. is \(4.4256974.9994\). It is equal to \(2V + 4\), by which it may be correctly tuned.

FOURENTH Major (XIV), or Quaterrizence, the octave or replicate of the major seventh, has the ratio of \(\frac{4}{15} = 1167 \Sigma + 23 f + 101 m\), and its log. is \(4.4256974.9994\). It is equal to \(2V + 4\), by which it may be correctly tuned.

FOURTEENTH Minor (14), the octave or replicate of the minor seventh: its ratio is \(\frac{9}{32} = 1120 \Sigma + 22 f + 97 m\), and its log. is \(4.4400925.3112\). It is \(V + 4\) 4ths, whence it may be tuned. (e)

FOURTH, in Music, is the numeral designation of an interval of four diatonic degrees, or literal gradations. Of these fourths, the different writers on music have mentioned a considerable variety, and by a still greater number of names, as follows; (see Plate XXX. Vol. II.) viz.

Bearing Fourth of Holden; its ratio is \(\frac{16}{21} = 240.0600765 \Sigma + 5f + 20 m\). See Lesser False Trumpet Fourth.

Comma-deficient Major Fourth (IV'), has the ratio \(\frac{243}{224} = 243 \Sigma + 5f + 21 m\); its common log. is \(4.8573324.9613\), \(4.73902 \times VIII = 26.44423 \times c\); is \(IV - C\), \(=4 + 3\), \(T + 1\), \(1 + \Sigma + 6f\), \(= 6f + 13\Sigma + 10\); it is also \(V + 3\), by which means it may be accurately tuned. It is the grave major fourth of Maxwell and Liston; the sharp fourth, or the greater fourth of some writers; the superfluous fourth of Chambers and Marsh; the double-deficient tritone, and the tritonus of Euler.

Comma-deficient Minor Fourth (4'), has the ratio \(\frac{326}{304} = 326 \Sigma + 6f + 21 m\); its log. is \(4.8804502.9278\), \(4.377117 \times VIII = 22.15311 \times c\); is \(IV - C\), \(= 4 + 3\), \(T + 1\), \(1 + S + 21\), \(= 21f + 12\Sigma + 5f\), \(= 5f + 11\Sigma + 8\Sigma\); it is also \(3\) 4ths - \(V - 3\), by which it may be tuned. It is the deficient fourth of Holden, the lesser fourth of Holden, the grave minor fourth of Liston, and the superfluous third of Good.

Comma-redundant Major Fourth (IV'), has the ratio \(\frac{512}{480} = 312 \Sigma + 6f + 27 m\); its log. is \(4.845249.3266\), \(4.500772 \times VIII = 28.44423 \times c\); is \(IV + C\), \(= 4 + 3\), \(T + 1\), \(S + 8\), \(T + 3\), \(S + 8\), \(= 4 + 3\), \(21\), \(27\), \(15\), \(6f\), \(= 6f + 15\Sigma + 12f\); it is also \(3\) 4ths - \(V - 3\), and may be so tuned. It is likewise the acute major fourth of Liston, &c.; the greatest sharp fourth, the sharp, the superfluous fourth of Benetrieder; the treble major tone, the acute tritone, the ancient superfluous or redundant tritone, &c.

Comma-redundant Minor Fourth (4'); its ratio is \(\frac{20}{33} = 265 \Sigma + 5f + 23 m\); its log. is \(4.689965.3150\), \(4.423958 \times VIII = 24.18311 \times c\); is \(4 + C\), \(= 11 + 3\), \(= 1X - V\), \(= 10 - 7\), \(= 3 + T\), \(= 5 + 3\), \(= 7 + 1\), \(= 4 + 3\), \(21\), \(c + 12\), \(f + 5\), \(= 5f + 15\Sigma + 10\Sigma\); it is also \(2V - VI\), by which it may be tuned. This is also the acute minor fourth of Liston, and his diminished (major) fourth, the redundant fourth of Chambers; the superfluous fourth of Galileo, and the greater fourth of Holden.

Deficient Fourth of Holden, has the ratio \(\frac{243}{320} = 243 \Sigma + 5f + 21 m\). See Comma-deficient Minor Fourth.

**Greater false Fourth, of the trumpet (IV + 1); has the ratio 8/11 = 281.102040 + 6 f + 24 m, and its log. is 0.8616973,0183.**

**Greatest sharp Fourth: has the ratio 512/729 = 312 + 6 f + 27 m. See Comma-redundant major Fourth.**

**Imperfect Fourth, of Good and Gregory; has the ratio 50625/34,54 = 228 + 4 f + 20 m; its log. = 0.8878851,0650 = 0.3724368 \times \text{VIII; } 20.781136 + c; \\
= 4 - 3 = 4V - 2 S = 20 c + 8 + 4 f = f + 12 C + 6 \Sigma; \text{ it is also } 4 + 4 + 4 + 4 + 4 III, by which it may be tuned. \text{ This is also the quadruple major semitone, } = 4 S.**
Least flat Fourth, of some writers; has the ratio

\[ \frac{231}{21} = 240.60766 \times 5f + 20m; \text{ its log.} = .8819006,3992, = .3923715 \times 11.1 = 21.80093 \times c. \]

Lesser False Fourth of the trumpet \( \left( \frac{1}{21} \right) \), &c.

has the ratio \( \frac{16}{21} = 240.60766 \times 5f + 20m; \text{ its log.} = .881906,7692, = .3923715 \times 11.1 = 21.80093 \times c. \)

Lesser Flat Fourth, of some authors; has the ratio \( \frac{1}{21} = 207.5 + 4f + 18m. \) Its logarithm is \( = .898185,6224, = .338224 \times 11.1 = 18.3798 \times c. \)

Major Fourth (IV), or Greater Fourth, has the ratio \( \frac{231}{21} = 207.5 + 4f + 26m; \) its logarithm is \( = .898193,6454, = .491833 \times 11.1 = 27.4423 \times c. \)

Major Fourth (IV), or Greater Fourth, has the ratio \( \frac{231}{21} = 207.5 + 4f + 26m; \) its logarithm is \( = .898193,6454, = .491833 \times 11.1 = 27.4423 \times c. \)

Redundant Fourth of Chambers; has the ratio \( \frac{231}{21} = 265 \times 5f + 23m; \text{ see Comma-deficient minor Fourth}. \)

Redundant (major) Fourth of Liston, has the ratio \( \frac{231}{21} = 265 \times 5f + 23m; \text{ see Comma-deficient minor Fourth}. \)

Schisma-excessive minor Fourth (4*); has the ratio \( \frac{231}{21} = 265 \times 5f + 23m; \text{ see Comma-deficient minor Fourth}. \)

Sharp Fourth, or Greater Fourth; its ratio is \( \frac{231}{21} = 301 \times 5f + 26m. \) See Major Fourth.

Sharp Fourth, of Benetrixier; has the ratio \( \frac{231}{21} = 312 \times 5f + 27m. \) See Comma-deficient major Fourth.
The following is the statistical abstract for 1811, including the town and parish:

- Inhabited houses: 227
- Families: 320
- Ditto employed in agriculture: 50
- Ditto employed in trade and manufactures: 75
- Males: 554
- Females: 765

Total population: 1319

West Long. 40° 57' 31", North Lat. of Fowey windmill, 50° 20' 7". See Polywhele's History of Cornwall; Maton's Observations on the Western Counties; and the Beauties of England and Wales, vol. ii. p. 410. (x)

FOWLING-PIECE. See Gun MANUFACTORY.

FOX, CHARLES JAMES, second son of Henry Fox, Lord Holland, and of Lady G. C. Lennox, was born on the 13th January O. S. 1748. He is said to have been extremely indulged in his childhood, and to have been gratified in all his humours, however whimsical or capricious. At an early age he was sent to Westminster school, and soon afterwards to Eton. There he was distinguished by his promising genius, his power in captivating the affections of his school-fellows, and the lead which he took in all their sports and frolics. From Eton he went to Oxford, where he was equally eminent for his literary attainments and his dissipated habits.

At a very early period of life he made a short excursion to the Continent; and in 1768, before he was of age, he took his seat in the House of Commons as member for the borough of Midhurst. His first appearance was in opposition to the popular politics of the day; and he was one of those who resisted the return of Mr Wilkes for Midldexes. Under Lord North, he was first a Lord of the Admiralty, and afterwards of the Treasury; but differed from the Premier on some questions, particularly on that of the marriage act. After the death of his father Lord Holland, he was exculpated from his seat at the Board of Treasury; and, his patronage having been already consumed by unbounded extravagance, he became unhappily much addicted to the gaming table. In the debates on the differences with the colonies in America, he came forward as a powerful speaker in opposition to the ministry; at first appearing as only the pupil of Burke, but soon rising as the equal, and in many respects the superior, of that accomplished orator. The American war, though popular in its origin, recommending itself both to the pride and avarice of the nation, yet, by the repeated failures of our military operations, soon became odious to the people; and, by the exertions of Fox and his friends, was finally condemned in Parliament. Mr Fox then became Secretary of State under the new administration, of which the Marquis of Rockingham was the nominal head; and several acts were passed, which tended to reduce the influence of the crown, and to enforce a greater degree of public economy. But the hope of peace, which the nation had been encouraged to entertain, was not realized by the new ministry; and the death of the Marquis of Rockingham produced jealousies in the cabinet, which ended in Mr Fox's secession. The Earl of Shelburne was advanced to the situation of prime minister, and Mr Pitt, at the age of twenty-three, was made Chancellor of the Exchequer. A general peace was concluded; but Lord North and Mr Fox, who had hitherto appeared as the most determined enemies to each other, having united
in a vote, declaring the terms of pacification inadequate, the treaty was condemned by Parliament, and the administration consequently resigned. A new cabinet was formed under the Duke of Portland, and Lord North and Mr Fox became joint Secretaries of State,—a coalition, which some have considered as fixing a stain on the political character of the latter; while others have marked it with high approbation, as a laudable suppression of party feuds for the good of the country. Mr Fox was, certainly, at the time, somewhat revolting to the moral feelings of friends, and of the nation; and produced a deep impression of the insincerity of public men. The only transaction of importance, during this administration, was the India Bill of Mr Fox, which he introduced with great ability, and which passed the House of Commons by a strong majority. It was represented by its advocates as a wise and generous rescue of the natives of India from oppression; but was censured, on the other hand, as not merely an unwarrantable violation of the India Company's charter, but also as a measure full of danger to the constitution, inasmuch as, by lodging the whole patronage of India in a few persons, it produced a degree of political influence, which might be equally pernicious, whether it was added or opposed to that of the crown. Some suggestions of this nature, privately conveyed to the royal ear by a person out of administration, caused its failure in the House of Lords; and a new administration was formed under Mr Pitt, in the face of a majority of the House of Commons. In consequence of a dissolution of parliament, many of Mr Fox's friends lost their seats in the House; and his own re-election for Westminster made the subject of a long and severe scrutiny, of which he loudly complained, as an unworthy persecution on the part of the court. Whatever were the views of Mr Pitt in the inquiry, whether to support the just rights of election, or to free himself from a political adversary, the House of Commons refused to concur in his wishes; and Mr Fox's return was sustained by a majority of nearly 40 votes.

For a long period, Mr Fox must be regarded, in his public life, as generally the opponent of Mr Pitt's measures; and, though his exertions, as his warmest admirers must allow, were sometimes calculated chiefly to harass the ministry, yet neither can it be denied, that, in many cases, they proved highly beneficial to the state. He vehemently opposed the commutation act, and the transfer of certain duties to the excise, a measure, of which the good effects are now generally admitted, and the commercial treaty with France in 1786, of which the principal fault certainly was, that it was too favourable to Great Britain to be long observed by the other country. He condemned also the propositions for assimilating the commercial regulations for England and Ireland, which nothing but the jealousy of political independence in the latter country could have enabled the opposition to set aside. He resisted especially the regency bill, during the king's illness in 1788; a question in which the two great political leaders of the country seem to have, in some degree, exchanged political principles. It was affirmed by Mr Fox, that the two Houses of Parliament had no other power than to declare the temporary vacancy of the throne, and that the Prince of Wales had then an unquestionable right, without any limitation in the prerogatives of royalty, to assume the vacant place. Mr Pitt protested against this doctrine, as little less than "treason against the constitution;" and maintained the right of Parliament both to appoint a regency, and to limit its powers, as circumstances might direct. He admitted, indeed, the expediency of nominating the Prince as regent, and of leaving him unfettered by any council; while Mr Fox also conceded the adjudication of the Prince's right to be the privilege of Parliament. It is scarcely possible to avoid the conclusion, that each party were in some measure, perhaps insensibly, swayed in their political views, by their own apprehensions and expectations. The bill was supported only by a majority; but the king's recovery happily prevented all further discussion of its principle, which is perhaps one of the most delicate that can be publicly agitated.

Mr Fox displayed all the vigour of his talents in pushing the trial of Mr Hastings; and it is worthy of remark, that the second article of the charge, of which he was the mover, was admitted by Mr Pitt as containing matter of impeachment. He succeeded also in resisting the design of the premier to prevent, by an armed mediation, the occupation by Russia of the conquered territory between the Bog and the Dneister; and thus probably saved the country from being involved in an expensive and unwarrantable contest. In a few instances, these rival leaders are found to have concurred in supporting some of the most important measures of finance, and most essential principles of the constitution. Mr Fox supported Mr Pitt's motion for reforming parliament, by abolishing 36 rotten boroughs; and approved of the bill for establishing a sinking fund. On the other hand, he received the concurrence of the minister in his declaratory acts for asserting the right of judges to judge in cases of libel. But the most gratifying instance of their agreement appears in the measures which were proposed for the abolition of the slave trade; and, throughout the whole of this cause, so interesting to humanity, the character of Mr Fox is placed in the most favourable point of view. He entered, from the first, and with the greatest ardour, into the condemnation of that infamous traffic; and, without waiting for any enquiry into its accidental bar- ritories, or its general impolicy, wished, as every man of right feelings must have done, to denounce it at once, as, in every aspect, iniquitous and inhuman. He was one of the many excellent and enlightened individuals in Great Britain, who hailed, with friendly feelings, the rising liberties of France in the commencement of the year 1789; but it has been considered as in some measure derogatory from his political sagacity, that he did not sooner detect, in the progress of that revolution, the principles of anarchy with which it was fraught. It was in the year 1790, in a debate on the army estimates, that the French revolution was first noticed in the British Parliament; and Mr Fox having expressed his approbation in general terms, Mr Burke took occasion to point out the dangers which it threatened to regular governments. This drew a reply from Mr Fox, guarding his commendations of the French patriots, yet differing from the doctrines of his friend; and, though both speeches were full of strongly complimentary expressions, a separation was unequivocally implied between these two eminent characters, who had so long pursued their political career as the most faithful associates. Even in a succeeding session of Parliament, after the King of France had remained another year as a prisoner in his capital, Mr Fox is understood to have characterised the revolution in that country as a stupendous and glorious edifice of liberty.
erected on the foundation of human integrity; and though he subsequently qualified his expressions, by limiting his approbation to the destruction of the absolute monarchy, yet his language unfortunately conveyed to multitudes, who revered his authority, or who wished to avail themselves of his name, a general sanction of French principles. He was very far, however, from being a republican theorist; and his lingering partiality to the French revolution may be ascribed to his general love of political freedom, his naturally ardent feelings, and particularly to his extremely unsuspicous mind, which may have led him to consider too much in the good intentions of the first revolutionists in France. When, in 1791, the French monarch was committed to custody, and preparing for trial, Mr. Fox expressed in Parliament a wish to interpose in his behalf, by some declaration of the opinion of the House; but afterwards concurred with Mr. Pitt in abstaining from all interference, lest it might serve only to exasperate the National Assembly. In 1792, when seditious societies in Great Britain were corresponding with the National Convention, and the Alien bill was proposed, in order to provide against Jacobin emissaries from France, Mr. Fox seemed to consider these precautionary measures as stronger than the apprehended dangers required; and, while he executed the murder of Louis XVI. he resisted the preparations for joining in the war against France, chiefly upon the principle, that whatever might be alleged as the ground of hostilities, the true object was to interfere in the internal government of the country. When a message from his Majesty, on the 12th of February 1793, announced the important intelligence, that the French convention had declared war against Great Britain and the States of Holland, Mr. Fox, while he still insisted that the conduct of the British government had not been sufficiently candid and conciliating, was willing that the address from the House to the Throne should convey a promise of support against every hostile attempt of France, and in such other exertions as might be necessary to procure such terms of pacification as might be consistent with the honour of his Majesty's crown, the interests of his people, and the security of his allies. There can now be little doubt, that it answered the purposes of the despotic rulers who successively directed the military energies of France, to involve the nation in war with foreign powers; and that their triumphant troops could scarcely be termed a nation of freemen resisting the invasion of tyrants; yet it must be allowed, that Mr. Fox's predictions, of the failure of the coalition against them, approached very near to the actual result. His forebodings, however, of the ruin of the British constitution, in consequence of the suspension of the Habeas Corpus Act, and the treason and sedition bills, have happily failed of their fulfilment; and, though the two last measures were no doubt infringements upon the freedom of the subject, yet as mere temporary enactments, they may be considered as justified by the alarming aspect of the times, and as sufficiently conformable to the spirit of our constitution, which supposes parliament to provide, by temporary laws, against special dangers. Even Mr. Fox's resistance to these bills evidently rested only upon his disbelieve of those seditious designs against the government, which could alone have rendered them necessary; and, although future events, particularly the confessions of O'Connor, have proved the existence of such reasonable practices, where Mr. Fox had no suspicion of their being entertained; the same discoveries have equally shewn, that he was most unjustly charged with participating in any revolutionary schemes. But so unfavourable was the impression made by his speeches in Parliament in that period of public agitation, that in 1798, his name was erased by his Majesty from the list of privy counsellors; and so decided, on the other hand, was his disapprobation of the conduct pursued by the ministry, that, contrary to the opinion of many of his political friends, he forbore his attendance in the House of Commons till his services might seem more likely to benefit his country. He appeared, however, in his place, in opposition to the triple assessment bill, the income and property tax, and particularly the Union with Ireland, which he condemned principally on the ground of its being effected by means of influence, and in defiance of the general wishes of the Irish people. He was occasionally drawn from his retirement by the state of continental affairs; and was ready to support every motion, which favoured the opening of negotiations for peace. He exerted all his powers especially in recommending a conciliating reply to the letter, which, in 1799, Bonaparte, as Grand Consul, addressed to the King of England, inviting negotiation; and, though it has since been admitted by those who concur in Mr. Fox's political views, that the able delineation given by Mr. Pitt of the principles and aims of the French Chief, was extremely correct, yet it is impossible to vindicate the lofty tone and irritating proposals expressed in the answer of the British government. When Mr. Addington's administration concluded the peace of Amiens in 1801, Mr. Fox, always consistent in pressing the spirit of pacification, joined with Mr. Pitt in approving, or rather accepting the peace, as the best that could have been expected. Indeed, however just we may regard the war in its commencement, it can scarcely be denied, that Mr. Fox faithfully pointed out several important errors in its progress, and in many respects gave good advice to his country. But his invariable and inveterate opposition to almost every measure of the administration, occasioned many of the truths which he uttered to be heard by many with nearly as invariable and inveterate prejudice. Upon the renewal of war in 1802, Mr. Fox spoke with great eloquence in support of peace; and must be allowed to have shewn, that, however clear our grounds of complaint against the conduct and designs of the French ruler, the direct and instant appeal to arms was neither justified by sound policy, nor enforced by strong necessity. The friends of Mr. Pitt, of Mr. Fox, and of Lord Grenville, having concurred without any plan of junction, in denouncing the inefficiency of the military system of the government, the prime minister announced his intention to withdraw from office; and Mr. Pitt recommended to the king the formation of a ministry on the broadest
est basis; but the mind of the sovereign was decidedly adverse to the admission of Mr Fox, who, together with Lord Grenville, continued in opposition. Upon the death of Mr Pitt, however, and in the difficult circumstances of the country at that time, his Majesty does not appear to have testified any reluctance to Mr Fox's appointment as foreign secretary of state; who, on his part, now advanced in years, and declining in health, can scarcely be considered as having been actuated in his acceptance by any views of personal ambition. One of the first acts of his administration, the introduction of the Lord Chief Justice into the cabinet, was made the subject of complaint in parliament; and such a measure, however vindicated by the right of prerogative, can scarcely be reconciled either with the views of expediency, or the principles of the constitution. In regard to foreign politics, the new government could not easily alter the course adopted by their predecessors; and Mr Fox therefore deemed it the most advisable plan to cultivate the connection, which still subsisted between Great Britain and the continental powers, and especially to draw a firmer alliance with Russia. In his financial measures, he adhered still more closely to those of his predecessor; and his increase of the property tax from 6½ to 10 per cent. was obviously rendered necessary by the state of the country. His military plans, which consisted chiefly of the training bill, and the conversion of the service of regulars for life into service for a term of years, though both of them commendable in their principle, and calculated to produce the best effects, were nevertheless obviously inadequate to supply that great and immediate addition of strength, which all parties had acknowledged to be wanting in present emergencies. His measures respecting Ireland, also, varied very little from those of Mr Pitt; and the Catholic claims were advised to be postponed. The public money, however, was not so lavishly applied to foreign subsidies; a milder exercise of power is understood to have taken place in Ireland; the interests of liberty were protected by the limitation of military service to a term of years; and, above all, the abolition of the slave trade, is sufficient of itself to immortalize the administration of Mr Fox and his friends. With these, and a few other exceptions, it must be admitted, that the change which had taken place, was more of men than of measures; that the new ministry made nearly the same apologies for the increase of public burdens, which their predecessors had used; and that the new opposition displayed nearly all that hostility and asperity towards administration, which they had condemned in the old. There is much justice, indeed, in what has been alleged by the friends of Mr Fox, that many things censured by him in the conduct of former ministers, could not, when done, be easily altered; and that it was only by the gradual application of better principles, that any great amelioration could be effected in public affairs. There can be no doubt, that many of his previous admirers were seriously disappointed, in perceiving so little apparent effect produced by his exaltation to power; and it can scarcely be denied, that these expectations, though unreasonable in themselves, had been too much encouraged by his general conduct in opposition. His administration, however, was too short in its duration to afford a full opportunity for the exertion of his talents, and the application of his principles. His declining health, also, when he entered upon the labours of office, must have contributed materially to enfeeble his hopes of accomplishing much as a public leader; and it is probable, that the prospect of being able to conclude an honourable peace with France was one of his principal inducements to accept the anxious and arduous station of a British premier. The negotiation for this great object, the last act of his political life, commenced in 1806, and originated in his indignant rejection of a proposal to assassinate the Emperor of the French. As a general basis for negotiation, he recommended "a peace honourable for both parties and their allies, and calculated to secure the tranquillity of Europe; and, as a more specific ground of the intended treaty, the French government verbally agreed to the principle of *uti possidetis.* But new objects of ambition arising to the French, and the health of Mr Fox rapidly declining, they departed from their verbal professions, and, with many personal compliments to the British Secretary of State, and a little rudeness to the British plenipotentiary at Paris, terminated the negotiation.

We have been unwilling to interrupt the preceding sketch of Mr Fox's public career, by advertting to the history of his private life; and there is little space left for more than a few slight notices on the subject. The irregular habits of his earlier years were not forsaken in the bustle of political contests; and, at one period, involved him in the greatest pecuniary difficulties, from which he was extricated by the subscriptions of his friends, upon the express condition of withdrawing his attendance from the gaming table. His better judgment seems to have condemned the immoral courses in which he engaged, and into which he appears to have frequently been drawn by unworthy associates, whom his indolent good nature, and easy urbanity, admitted too freely into his friendship. He gave proof of a taste for purer pleasures, by the ease and alacrity with which, at seasons of occasional leisure and retirement, he recurred to literary pursuits and epistolary compositions. Even in his youth, when the marriage act was under the consideration of parliament, he gave a public testimony to the miseries of a dissolute life; and, on several other occasions, clearly shewed, that he did not approve the lax morality of the French philosophy. Though deficient, therefore, in practice, in a degree not to be justified, and particularly to be lamented in a character so distinguished in other respects; he ought not to be regarded as having been, upon principle, a mere dissipated man of pleasure. His marriage, which was first announced in 1802, though said to have taken place in 1780, may be considered, it has been justly observed, as "a homage which he paid to virtue;" and his later years were spent with little interruption in the simple enjoyments of domestic life; or in an assiduous attendance on public duty. When residing in his favourite retirement at St Anne's hill, as stated by one of his biographers, he usually rose before eight o'clock in the morning; breakfasted, and read the newspapers; perused some Italian author with Mr Fox; spent an hour or two in study; sat down to a frugal but plentiful dinner at three or four; drank a few glasses of wine, followed by coffee; walked or conversed till tea-time; employed the evening in reading, or listening to the reading of history, till near ten; and concluded the day with a slight repast of fruit, or of something equally trifling. When residing in town, he generally went to his office at eleven o'clock, where he remained until three; and, as long as his health permitted, continued to bestow the most punctual and active attention upon his duties, frequently even directing in person the more mi-
nute transactions of his department. About the end
of May 1806, his health was visibly affected, and his
disorder was pronounced to be of a dropical nature.
On the 7th of August, he underwent the operation
of tapping; and, for several days after, was considered
to be in a very hazardous state. He requested to be re-
moved to his residence at St Ann's Hill; but with diffi-
culty reached the house of the Earl of Devonshire, at
Chiswick, where a second tapping was performed on
the 9th of August. After the operation, he expe-
rienced a temporary revival; but, in a few days, every
hope of his recovery vanished, and his friends were
permitted to take their leave of him. During his ill-
ess, he is said to have expressed an anxious wish that
he might live to witness the abolition of the slave trade;
and he left it as his dying charge to his political friends,
that they should persevere in their efforts for the ac-
complishment of that glorious object. In his last mo-
mments, he put the hand of Mrs Fox into that of Lord
Holland, and then, placing his own upon theirs, "God
bless you," he said, "I die in peace; I pity you."
These are reported to have been the last words which
he uttered; and he expired on the 13th of September
1806, in the 59th year of his age.

At a time when even Mr Fox's nearest relatives and
warmest friends have declared that insuperable objec-
tions exist to a memoir of his life, it is no easy task to
offer even an obscure and unpretending sketch of his cha-
ter; and, were there not some approved and experi-
cenced guides to point out the leading marks, we should
never have attempted the outlines of such a portrait.

Mr Fox, in his person, was rather under the mid-
stle stature; and, though celebrated for agility in his
youth, was of a corpulent habit during the greater part
of his life. His chest was capacious, his shoulders
broad, his hair dark and thick, his complexion dusky,
his eye-brows black and bushy, and his countenance,
especially in the course of argument, peculiarly ani-
med and expressive.

In his political life, he had been so constantly and
eagerly engaged in compassing the overthrow of mi-
istry, that he will probably appear, to every indifferent
observer, more in the character of a determined
party-leader, than of an enlightened statesman; and
yet it may be doubted whether his ardent attachment
to the political body of which he was the head, did not
proceed as much from the warmth of his friendship, as
from the spirit of party. This consideration may at
least account for honourably as most others for the un-
questionable fact, of his having consented, in the course
of his public career, to join every one of those whom
he had systematically opposed; and which, though it
will not exempt him from the charge of inconsistency,
may vindicate his name from the more heavy reproach
of insincerity. He was almost uniformly the unlaun-
ched champion of constitutional freedom; and it can
scearcely be doubted, that his resolute resistance to the
slightest encroachments of government may have often
acted as a salutary restraint. Yet, in some instances,
he was opposed not merely to the popular cause, as in
the case of Mr Wilkes, but even to the principles of li-
iberty, as in those of the Regency Bill, and the admis-
sion of the Chief Justice into the cabinet. As a speak-
er in Parliament, Mr Fox stands in the first rank; and,
though originally the pupil of Mr Burke, he soon dis-
played more commanding powers. He was more ve-
iment in manner, more forcible in argument, more
consummately master of the science of debate. He
sometimes hesitated in the commencement of a speech,
frequently indulged in digressions, and occasionally
even in repetitions, or gave loose to a flow of popular
declaration, instead of senatorial reasoning; but he was
always fluent when his feelings were roused, and
was able, with the utmost skill, to tread back his steps,
when hard pressed, without seeming to retreat from an
intenable position, or to return from an unnecessary
digression. Whatever became of his subject, he bent
his whole force to trample down his enemy; and exer-
cised a degree of talent in parliamentary warfare which
has never been rivalled. He was equally prepared to
perplex his adversary by ingenuity, to overawe him by
violence, or to overwhelm him with a torrent of elo-
quent abuse. He is acknowledged to have been pecu-
larily successful in reply, never failing to take advan-
tage of the concessions or contradictions of his oppo-
ents, and to turn upon them with their own weapons.
"I knew him," says Mr Burke, in a pamphlet written
subsequently to their separation, "when he was nine-
teen; since which time, he has risen by slow degrees
to be the most brilliant and accomplished debater that
the world ever saw."

In the accomplishments and endearments of private
life, Mr Fox's character was peculiarly attractive; and
he was at all times remarkably beloved in the circle of
his friends. He was frank and unassuming in man-
ners, kind and gentle in dispositions, and, according to
those who knew him best, possessed even the simpliti-
cy of a child. "He was," says Sir James Mackintosh,
"gentle, modest, placable, kind of simple manners, and
so avers from parade and dogmatism, as to be not on-
ly unostentatious, but even somewhat inactive in con-
versation. His superiority was never felt, but in the in-
struction which he imparted, or in the attention which
his generous preference usually directed to the more
obscure members of the company. His conversation,
when it was not repressed by modesty or indolence,
was delightful. The pleasantry, perhaps, of no man of
wit had so unlaboured an appearance. It seemed ra-
ther to escape from his mind, than to be produced by
it. His literature was various and elegant. In clas-
sical erudition, which, by the custom of England, is more
peculiarly called learning, he was inferior to few profess-
scholars. Like all men of genius, he delighte to take
refuge in poetry, from the vulgarity and irritation of
business. His own verses were easy and pleasing, and
might have claimed no low place among those which
the French call Vera de Société. He disliked political
conversation, and never willingly took any part in it.
Perhaps nothing can more strongly prove the deep im-
pression made by this amiable part of his character,
than the words of Mr Burke, who, in January 1797,
six years after all intercourse between them had ceased,
speaking to a person honoured with some degree of Mr
Fox's friendship, said, "To be sure, he is made to be
loved;" and the emphatical words were uttered with a
ferveur of manner, which left no doubt of their heart-
felt sincerity. From those qualities of his private, as
well as from his public character, it probably arose,
that no English statesman ever preserved, during so
long a period of adverse fortune, so many affectionate
friends, and so many zealous adherents.

Mr Fox was distinguished from his youth as a lite-
rary character; and various productions of his pen at-
test the elegance of his taste, and the accuracy of his
classical attainments. His compositions, while at Eton,
his fugitive poetry, and several of his speeches; his
FOX ISLANDS. A great chain of islands stretches across that part of the North Pacific Ocean bounded by the peninsula of Kamtchatka on the Asiatic continent, and that of Alaska in North America. The first of these towards the west, was discovered in the earlier part of the eighteenth century, by Capt. Vitus Behring, a Dane in the Russian service, and named after him; and the second, twenty-seven miles from it to the east, was called Copper Island. Both were greatly frequented by the Russians, on account of the valuable furs obtained from the animals of the surrounding seas; and a company of adventurers from Kamtchatka having prosecuted farther discoveries, ascertained, in the year 1745, that other islands lay farther to the east. Having ventured on one of them to kill sea otters, they continually advanced farther on; and after various successes and discomforts, at length, by means of intermediate islands, reached the American continent. This chain was known by different appellations bestowed on certain groups of it, which the progress of discovery proved were only a short way detached from the rest; and they were in general divided into the Aleutian, Andreanov, and Fox islands: but late navigators are disposed to include the whole chain under the name of Aleutian or Fox islands; while it is sometimes proposed, though without any apparent good reason, to except Behring's and Copper Island from the number. It is not difficult to anticipate, however, that this separation will soon be abandoned. The Fox Islands in position resemble a circular arc, extending from 165° to 193° of longitude east; the most southern island lies in about 53° of north latitude, and the most northern, at each extremity, in 55°. These islands are of all different sizes, below 104 miles in length, which is that of Behring's Island, and are divided by channels of very unequal width. This last is 192 miles from the harbour of St Peter and St Paul, in Kamtchatka. Copper Island, which is mountainous, and twenty-five miles long, lies due east, and is the first of the Aleutian, or Fox Islands, properly so denominated. Attwo is 60 miles in length, and 188 miles from Copper Island: Next is Agattoo, twenty miles distant, and six in length; then Buldyr, an oval rock, six miles by ten, distant 70 miles; and so on, regarding the rest, to Omnak, Oonalashka, and Oomenak, next to Alaska. Some of these islands are disposed in clusters; and although the number of the Fox Islands was originally calculated at sixteen, many more are now included. Indeed, to judge by recent occurrences, they appear to receive accessions: In the year 1795, a thick fog having obscured a rock which was the favourite resort of the Aleutians in their hunting excursions, thirty miles north-west of Oonalashka, they found the sea, on approaching it, in a state of ebullition, with vast quantities of vapour rising around. Concluding that it was haunted by evil spirits, no one would again venture thither during the lapse of five years, when a few more courageous than the rest, ascertained that a volcanic island had sprung up, discharging fire and smoke from a crater in its summit. In the year 1806, this island had augmented to about twenty miles in circuit; lava flowed from it down into the sea, and the heat was so great as to preclude landing on that particular side. There are always some volcanoes in activity among these islands; and others, once known to have blazed, are now quiescent. Earthquakes are common from such subterraneous fires, and the concussions are violent. Huts were thrown down in 1802, when a long-extin-
guished volcan in Oonalsika began to burn, and the flames from the new erupted island ceased; but they were renewed soon after. The Fox Islands are of barren aspect; the mountains are conspicuous, being in general high and conical, and covered with snow during a great portion of the year. Nothing is produced in the whole course of the Aleutian chain, except low shrubs and bushes. There are no trees; but, to compensate for this defect, recourse is had to drift wood, often of large size, floated on shore from America and other countries by the tides. The lower valleys produce abundance of fine grass, but the islands are destitute of cattle; and the different indigenous roots, as also potatoes, recently introduced by foreign settlers, which afford subsistence to the inhabitants. Berries are collected, and laid up for winter provision.

Considerable variety of fish frequent the surrounding seas, such as whales, salmon, cod, herring, and halibut, of such enormous size as to weigh several hundred pounds. These are not common food, but they are cut to pieces in the water when caught, from being too heavy for the frail canoes of the natives. On their first discovery, the Russians found innumerable phoœce, from which they obtained valuable furs; and for many years they continued to kill thousands of sea otters, whose skins bore a high price at that time, and still higher now, because, from unicessing pursuit, their numbers are wonderfully diminished. Not above two or three hundred are at present taken annually, whence their total extirpation in a short time is anticipated. But others are of even greater importance to the inhabitants, which are as ardently sought as the sea otter by strangers. Of one particular seal they eat the flesh; oil is extracted from its fat, which serves to illuminate and warm their huts; the sinews are fashioned into thread; clothes, shoes, and household utensils, are made of its skin; its paunch blown up, is used for holding liquors; and the esophagus is fashioned into boots, impenetrable by water. Nor is this all, for the thin membrane of the entrails is converted to a substitute for glass, in admitting light to their subterraneous habitations; and the whiskers are composed into plumes for ornamental head-dresses.

The feathered tribes, particularly the aquatic kinds, are also numerous here, such as wild geese and wild ducks, which are caught in spring, and salted for winter provender. Some of the rocks afford a retreat to gulls and alks during the breeding season, when their eggs are collected and preserved for the same purpose. Eagles, partridges and buntings, are among those found always on shore, and there are some species migratory.

Quadrupeds. When the Russians first discovered the Aleutian chain, they obtained the skins of foxes still more easily than those of the sea otter, and yearly carried away many thousands. These animals were so abundant on the Fox Islands, when restricted to a smaller portion of the chain, that they thence received their name; and Steller, an ingenious naturalist, who wintered on Bel-tring's Island, has left an interesting description of the habits of those found there. But from the same committing destruction, they are now almost as much reduced in proportion as the sea otter, which has induced the hunters to extend their snares still farther east. Foxes and mice are the only indigenous quadrupeds which the later visitors have observed here; but settlers have endeavoured to introduce hogs at Oonalsika, and, for want of other food, have supplied them with fish. This is said to render the fat thin and oily, and to impart a disagreeable fishy flavour to the flesh. The same has been the case with poultry fed on dried fish, which the Russians have likewise attempted; the fat becomes oily, and the flesh soft and spongy.

The natives of the Aleutian Islands are of middle size, of a very dark brown and healthy complexion, and resembling an intermediate race between the Mongul Tartars and North Americans. The face is in general round; the nose broad, small, and compressed; the eyes black; and the hair, which is strong and wiry, of the same colour. That of the men is cut short; by the women it is likewise cut short before, and made into a chib on the back of the head. The latter are rather handsome, and very complaisant. Both sexes, unlike uncivilized nations, are clean in their person; and their features, which are strongly marked, have an agreeable and benedict expression.

It is singular, that among the greater part, if not all the savage tribes with which Europeans are acquainted, some artificial disfigurement of the body is accounted ornamental. The Aleutian females practice tattooing, particularly of the upper lip, neck, arms, and chin; punctures are made in the flesh, and a sort of coal-dust or charcoal rubbed in. By this means, while the men carefully eradicate their beards, the women, by the bluish tinge, exhibit the appearance of having acquired one. But from the Russian settlers explaining to the younger females, that they do not esteem these ornaments as any accession to their beauty, tattooing has rather been brought into disrepute, and is now on the decline. However, they still practice a custom much more tedious and discrediting, in the perforation of the under lip, into which bones suspending beads and other trinkets are inserted, while the whole are retained by a kind of button in the inside of the mouth. Here in like manner, the settlers have found means to signify to the Aleutian females, that their beauty is not embelished by it, and the custom is daily decreasing. The ears of the women are perforated all around with holes, to which beads are suspended; and the nose of the men is likewise perforated to receive a piece of wood or bone the size of a small quill, to which strings of glass beads are hung on solemn occasions.

There is little difference in the external clothing of either sex, the upper garment being a kind of frock or surtouf, called parka, made of seal-skin, and formerly of that of the sea-otter, or of the skins of birds. Though simple in form, it is often neatly and variously ornamented; and the seams figured with stripes of thin leather, ingeniously worked or dyed of gaudy colours, or long white goats hair, brought hither as an article of trade from Siberia. So much care and attention is bestowed on one of these frocks, that sometimes a whole year is occupied in completing it. The Aleutians have besides a kamleika, or rain garment, made of the entrails of the seal, which, being of a mucilaginous substance, excludes the water; and although the pieces are only three inches broad, the whole are so neatly united, that the kamleika, though exposed a whole day to rain, is never penetrated. The exterior part of the Aleutian costume is now undergoing some change, by the substitution of coarse cotton, or sail-cloth. One of the most important parts of dress is a wooden hat fashioned so as to project over the eyes like an umbrella. The material composing it is not only extremely scarce, but difficult to be formed into any shape with the rude and imperfect tools of the islanders. After obtaining a thin plank, by laborious reduction, its ends are drawn together, and secured with tendons, an operation always difficult and of uncertain success. It is then
The Aleutians dwell in excavations of the earth, the sides of which are lined with beams or poles of driftwood washed ashore, inserted to support a roof formed of similar materials. These excavations are from 20 to 40 yards in length, and between six and ten in breadth; earth is thrown over the roof, which affords a soil for vegetation, so that after the habitations have stood some time, and are overgrown with grass, an Aleutian village bears no imperfect resemblance to an European church-yard. Fifty, or even an hundred and fifty individuals, dwell in the different divisions of the hut, which is lighted by a small window covered with the membraneous intestines of the seal, or with dried fish skin; and into which they descend by an aperture that at the same time gives egress to the smoke. But little cold is felt within, and their habitations are seldom heated with fire. Travellers affirm, that they are so warm that the inhabitants sometimes sit naked in them. Their different divisions are made by partitions of seal skin.

As the chief subsistence of the Aleutians is derived from hunting and fishing, a large portion of their time is devoted to these pursuits; and the greatest display of their art is in the construction of their canoes and weavings. The former are remarkably neat, consisting of a wooden framework covered with leather, and in the inside is a hole to receive the body of the navigator sitting, around which a seal skin is so tightly drawn as to exclude the water. In general, this vessel contains only one person, sometimes two, and rarely three. The length of the first is about eighteen feet, the breadth nearly two feet, and the depth eighteen inches, lightly yet firmly made, and capable of withstanding a considerable sea; insomuch, that an Aleutian, in moderate weather, can paddle his baidarka, as it is called, ten miles an hour, and can retain his seat in security, while his breast is washed by breakers. Neither is much apprehension excited by storms; for several baidarkas, when bound together, easily resist the waves. Billings, a late voyager, speaking of these vessels, exclaims, "If perfect symmetry and proportion constitute beauty, they are beautiful: to me they appeared so beyond any thing that I ever beheld. I have seen some of them as transparent as oiled paper, through which you could trace every formation of the inside, and the position of the natives sitting in, and the vessels are adorned with painted and plumèd bonnets, together with his perfect case and activity, added infinitely to its elegance." The beauty and construction of the baidarka are the subject of great emulation among the islanders. They have another large open boat, called a baidar, capable of holding fifteen or twenty people, which was formerly the common property of a village, but all of them are now in possession of the Russians.

Should a whale be discovered, the Aleutians follow it in their canoes, and watch the opportunity of raising its head to breath, to pierce it with a dart near the pectoral fin; then retiring while the animal grows faint with the loss of blood, they revisit the spot frequently in the course of the day, until at length, finding it dead, they tow it ashore. The right of property is determined by the point of the weapon which occasioned the mortal wound; a fact not difficult to ascertain, as all their implements have a particular mark. But the Russians always claim half of the whole fish. These darts, which are about four feet and a half long, are feathered; some are coloured red, some black, and fashioned differently for the different animals against which they are to be directed. They are thrown with
much force and precision, along a small board held horizontally, to the distance of sixty yards. They have likewise lances, bows, and arrows; but warfare among them is now unknown.

The Aleuts show much neatness and dexterity in their different works. Besides the fabrication of arms and baldrics, the men occupy themselves in carving diminutive figures of terrestrial or aquatic animals from the teeth of the sea cow, which are much harder than common ivory; and the women are engaged in making fine mats, little baskets, and pocket-books of straw, particularly during the long winter evenings. The latter are woven together with so much regularity, and in such symmetrical figures, that they might be supposed the work of European artists. They also dye various ornamental substances, as straw and leather, of fine and florid colours, with very simple materials.

Though reputed savages, the Aleuts are far from being deficient in capacity; they are mild, polite, and hospitable; and, in their intercourse with Europeans, are diligent and submissive; but, if roused by offence or maltreatment, they become rash and malevolent, regardless of all danger, and even expose themselves to certain destruction.

Dancing to the tambour or drum, with an accompaniment of pebbles rattled in a blown bladder, is here a favourite amusement, which is free from those lascivious gestures usually seen among barbarous tribes. Both sexes, clothed in their best attire, with richly ornamented head-dresses, join in the dance; but the masks which they formerly wore on such occasions are said to be laid aside. An amusement among the young men of the island of Tanaga, consists in leaping from the skin of a large sea-lion held up and stretched out by some of their companions, from which they spring to an astonishing height. Their love of snuff and brandy is very strong; and they will be content to labour a whole day for a single leaf of tobacco, which they contrive to grind to powder, adding a mixture of ashes and water.

Many islands of the Aleutian chain had a very considerable population, when originally visited by Europeans; but the people, along with the animal tribes, have been continually declining. Between the years 1750 and 1760, the inhabitants of Oonalashka were calculated at ten thousand; the males of the whole islands were judged not to exceed 1100 or 1500 about the year 1790; but, in 1806, their number was supposed to be reduced to 300. Probably there was a large preponderance of females, owing to various circumstances in their mode of life. Northern nations are seldom populous; and, with few exceptions, nature seems there to be alike hostile to animal and vegetable increase. It is the oppression, however, which the Aleuts have suffered ever since they became first acquainted with Europeans, that has progressively diminished their numbers. At first, they ventured to resist the usurpation of the Russians; but they were speedily subjugated, and are now held in a state of abject slavery. Their islands are resorted to solely for the profit and convenience of their invaders, to whom they pay a tribute in furs; and they have admitted of permanent establishments upon them, which send out parties of hunters, who compel the attendance of the natives. Sometimes, in the plenitude of their authority, they dispatch the hunters to distant islands, from whence many of them never return, or carry them to the continent of America, where the animals have hitherto had a wider range to escape destruction. Formerly, on arriving from Ochotzak or Kamtschatka at any of the inhabited islands, the Russians were accustomed to take a few inhabitants as hostages for their security; but now they assume possession of a village as if it belonged to themselves; distribute their traps, to be employed by the men in catching foxes; select such women as please them best; and exercise a most despotic sway over the whole. Yet the state of their hunters is represented as very miserable. They are engaged by a trading company, which pays them little regard; they remain eight or ten years together among the Fox Islands, suffering hardships and dangers, and so much exposed to the ravages of the scurry, that not many survive to revisit their native land. See Forster's Voyages in the North; Coxe's Russian Discoveries; Cook's Third Voyage, vol. ii.; Billing's Geographical and Astronomical Expedition; Langsdorff's Voyages and Travels. (c)

FOY. See HUNTING and MAMMALS.

FOYERS, FALL OF, a celebrated and most beautiful cataract in the Highlands of Scotland. It is situated in the county of Inverness, and district of Stratherrick, 19 miles south-west of Inverness, and close by the military road from thence to Fort Augustus. It is on the river Feshill, a mountain stream of considerable magnitude, which, after a rapid course of about seven miles in a northerly direction, through the rugged track of Stratherrick, precipitates itself into Loch Ness, on the south-eastern side, about half way betwixt the eastern and western extremities of that noble lake, at the romantic seat of Mr Fraser of Foyers.

This cataract is about a mile from the brink of the lake, the banks of which rise so suddenly, that the perpendicular height from its surface to the fall is not less than 300 feet. The river at the commencement of the fall becomes narrowed, by the closing of the rocks on each bank, to little more than seven or eight feet. It thence shoots forth in tremendous impetuosity over a precipice of smooth, black granitic rock, forming an uninterrupted, and almost perpendicular water fall of 165 feet from its commencement to the surface of the pool below. The chasm, or gully, into which it descends, is of a circular form, about 50 or 60 feet diameter at the bottom; its sides are wooded and rugged, and formed in many parts of rock quite perpendicular, or nearly so, and of great extent, tapering on each side of the river to the height of 350 feet above the surface of the pool, that is, 100 feet above the commencement of the cataract.

The station where the best view is to be had of this superb fall, is a projection of rock, which, on the east side of the river, extends across it so far as to bring the spectator directly opposite the face of the cataract. But this projecting rock is still 80 feet perpendicular above the bottom of the fall; nor is it practicable to have a view of it from a lower station. The upper surface of this rock is covered with grassy turf, which, from its being incessantly bedewed with spray, is ever fresh and vegetating, and has from thence obtained the name of the Green Point.

When the river is swollen after rain, on the melting of the snows on the southern mountains, the quantity of spray raised is so great, that the above-mentioned station cannot be occupied with safety; such floods of water being thrown upon it, as will in a moment thoroughly drench, or perhaps sweep away the adventurous spectator. On such grand occasions, incessant torrents are seen to flow down all sides of the immense circular basin into which the water falls; a strong cur-
rent of air is forced up from the bottom, and seems to agitate the water, as it pours from the rocks or the bushes on their surface, and to raise a cloud of spray into the atmosphere, distinctly visible at the distance of 10 or 15 miles, and not less in height than 600 or 700 feet. The writer of this article has frequently, on such occasions, seen a most beautiful rainbow formed by it, occupying a complete segment of the heavens as in an ordinary shower of rain. The inverted rainbow is also very beautifully seen at the bottom; but this fine phenomenon is observable only when there is less water in the river.

The water of this river is very strongly impregnated with moss or peat earth, so that its colour, when descending the cataract, is pretty nearly that of porter drawn from a cask; but no sooner does it strike the surface of the pool, than it flashes of the most brilliant whiteness, as if it were bursting forth into a flame, or like bluish smoke issuing from a kindling mass of wetish straw.

It has been suggested by some, and perhaps not without probability, that this conspicuous fall has given name to Loch Ness: for in the Gaelic, or Erse language, ness signifies a water-fall, and Loch-an-ness is the Loch of the fall. This is to us more probable than that ness should come from the Danish or Saxon word nesse, signifying nose or promontory, which has undoubtedly given name to many places on the sea coast of this island. For what propriety would there be in applying this word to Loch Ness? It is not a nose or projecting promontory like Caithness, Buchaneness, Fife ness, and many others.

It is worth any person's while who inspects this cascade and its scenery, to ascend to the bottom of the large gully, about 100 yards further down the river than the fall. He will there see masses of rock tumbled on one another of a size which, by viewing them from above, he had probably little conception of, and behold nature in an aspect of wild and indescribable magnificence, beyond what even poets usually represent.

Not a mile farther up this river, is another very fine waterfall, 37 feet high, nearly perpendicular, and also uninterrupted. A bridge is thrown across the river, immediately below this fall, and the height from its ledge to the water is 60 feet. These measurements, as well as those given of the great fall below, were taken by the writer of this article, with all possible accuracy, by a line. He had the opportunity of attending particularly, for several years, to the sublime phenomena of the Fall of Foyers.

FRACTIONS. See Algebra and Arithmetic.

FRACTION. Greater (F), in Music, is an interval discovered, and so named, by the indefatigable Mr Marmande Overend; its ratio in numbers is

$$F = \frac{d + 2f}{3d + 2f}$$

(1) = 14:12, 12:7, 7:5, 5:3, 3:2, 2:1.

FRACTION; Lesser (f), is the smallest interval, except one (m), that is known; which was discovered, and so named and marked, by the late Mr Overend; and has

Ancient Gaul comprehended the whole country between the Pyrenees, the Alps, the Rhine, and the Ocean; it was therefore of greater extent than modern France, as it existed previously to the Revolution; for to the dominions of that kingdom must be added, to form an accurate and complete estimate of the size of ancient Gaul, the duchy of Savoy, the cantons of Switzerland, the four electorates of the Rhine, and the territories of Liege, Luxembourg, Hainault, Flanders, and Brabant. Gaul was added to the dominions of the Roman empire, principally by the valour and talents of Julius Caesar; but it was not divided as a portion of that empire, till the reign of Augustus. This monarch introduced a division equally adapted to the course of the rivers, the progress of the legions, and the most prominent national distinctions, which had comprehended above 100 independent states. The colony of Narbonne gave its name to the sea coast of the Mediterranean, LangUEDOC, Provence, and Dauphine; the government of Aquitaine extended from the Pyrenees to the Loire; the celebrated colony of Lugdunum or Lyons bestowed its appellation on the country between the Loire and the Seine, which, however, was originally denominated Celtica Gaul. Beyond the Seine the Belgic division lay; this portion of Gaul, in more ancient times, had been bounded only by the Rhine; but a short time before the conquest of Gaul by Julius Caesar, the Germans being superior to the Gauls in number and valour, and like all savage nations, and many modern ones, regarding this as a sufficient reason for attacking their less powerful neighbours, had seized on a considerable part of the Belgic territory. The Romans gave to this portion the names of Upper and Lower Germany for no other reason, but because it was inhabited by people who had passed into Gaul from Germany. From this sketch of ancient Gaul, as compared with modern France, it will be seen, that the latter comprehends the whole of the Narbonnese, Aquitaine and Celtic, or Lyonnaise divisions of the former, and part of the divisions which were called the Belgic and the two Germanies.

The modern name of France is derived from the Franks. About the year 240, a confederation was formed under the name of Franks, by the inhabitants of the Lower Rhine and the Weser, who, in the time of Tacitus, passed under the appellations of Chauci, Cheruci, Catalii, &c. The first, in their inaccessible morasses, had long defied the Roman arms; the Cheruci were proud of the fame of Arminius; and the Catalii were formidable, on account of their firm and intrepid infantry. In the reign of Gallienus, they threatened Gaul; but at this time their ravages took another direction, and Spain and Africa trembled at their presence. For a great number of years afterwards we lose sight of the Franks, but when the throne of Valentinian was powerfully assaulted by Attila, they gained possession of part of Gaul, a small village between Louvain and Brussels, having been the residence of Clovis, the first of their kings mentioned in authentic history. Even before this conquest, they had established the right of hereditary succession in the noble family of the Merovingians. The symbol of military command was a buckler, on which the princes of this race were elevated; and the royal fashion of long hair was the exclusive mark of their birth and dignity; while the rest of the nation were obliged, either by law or custom, to shave the hinder part of the head, to comb the hair over the forehead, and to content themselves with two small whiskers. The Franks were distinguished from the inhabitants of the country in which they had now fixed themselves, by their lofty stature, and blue eyes; by their close apparel; their weighty sword suspended from a broad belt; a large shield; and their expertise in running, leaping, swimming, and darting the javelin or battle-axe with unerring aim.

Of the particular circumstances attending the extension Clovis of the conquests of the Franks, little is known: their regular and connected history begins with Clovis, in the year 481. This monarch achieved the conquest of Gaul, by the defeat of the Roman governor; and by his marriage with Clotilda, added Burgundy, of which her father was sovereign, to his dominions. Clotilda converted her husband to Christianity, and the conversion of his subjects followed. Clovis conquered Aquitaine, but retained it a short time; he died in 511. In the last year of his reign, he reformed and published the Salic laws; a few lines of these, which debarred women from inheriting what were called the Salic lands, have been applied as precluding females from the succession to the French throne.

The successors of Clovis were in general weak and wicked, till, on the death of Dagobert II. 638, who left two infant sons, the sovereignty was taken from them by the mayors of the palace, who were the first officers of the royal household. This office, from a personal dignity, became hereditary in the family of Pepin Heristel. His son, Charles Martel, succeeded to the power of his father, though he still retained the name of mayor of the palace. He delivered France from the ravages of the Saracens, by a dreadful battle, in which they were utterly defeated, fought between Tours and Poictiers, A.D. 732. His grandson, Pepin le Breuf, removing from the throne of Merovingian race, assumed, by the authority of a papal decree, the title of king, and reigned for seventeen years with dignity and success; the founder of the second race of the French monarchs, known by the name of the Carolingian race. In his time, the monarchy of the Franks was divided into two large districts, Austriæ and Neustria. On his death-bed, he called a council of his grandees, and, with their consent, divided his dominions between his two sons, Charles and Carloman.

Carloman dying a few years after his father, Charles Charlemagne succeeded to the indivisible sovereignty. This monarch, so honourably known in history by the name of Charlemagne, reigned 45 years, during which period he extended the limits of his empire beyond the Danube; subdued Dalmatia, Istria and Dacia, all the barbarous tribes to the banks of the Vistula, made himself master of a large part of Italy, and attacked the Saxons, Saracens, Bulgarians, and Huns with success. The Pope first crowned him King of France and the Lombards, and afterwards Emperor of the West. He had no fixed capital, and even
in his lifetime he divided his dominions among his children: he died A.D. 814, in the seventy-second year of his age.

In the time of Pepin le Bref, the system of annual parliaments, held first in March, and afterwards in May, had been established or restored. Charlesmartine ordered these assemblies to be held twice a year, in spring and autumn. The business of the first assembly was to prepare and digest what the second was to enact into laws. Of this assembly he constituted the people a part, so that it consisted of three estates. The sovereign never was present, unless to ratify its decrees. In this reign also, the kingdom was divided into provinces and districts; the latter were under the superintendence of royal envoys, chosen from the nobles and clergy, who were bound to visit their territories every three months, and to make their reports to the sovereign at the general assembly.

Of all Charlemagne's lawful sons, only Louis le Debonnaire survived him, who was consecrated Emperor and King of the Franks, at Aix la Chapelle, A.D. 816. Having very imprudently divided his territories, very soon after his succession, among his sons, they made open war against him, and he was compelled to surrender himself a prisoner to his rebellious children. His spirits were thus broken, his health decayed, and he terminated an inglorious and turbulent reign, A.D. 840.

Lotharius, his eldest son, was now emperor; but the quarrels among the brothers, which had begun even in their father's lifetime, still continued. Lotharius, in conjunction with Pepin his brother's son, took up arms against the two other sons of Louis, Charles the Bald, a son by a second marriage, to whom Aquitaine had been given, and Louis, who had received Bavaria from his father. A dreadful battle was fought at Fontenay, in which Lotharius was defeated. A council of bishops was immediately held; Lotharius was deposed, and his conquerors were permitted to reign by the clergy, on the condition of implicit obedience to spiritual authority. Lotharius, however, contrived to accommodate matters with his brothers in such a manner, that they agreed to a new division of the empire. By this division, A.D. 843, the western part of France, called Neustria and Aquitaine, was assigned to Charles the Bald. Lotharius retained the title of Emperor, with the nominal sovereignty of Italy, and the real possession of Lorraine, Franche Comté, Provence, and the Lyonnais; while the kingdom of Germany was allotted to Louis.

On the death of Lotharius, Charles the Bald assumed the empire, having purchased it from the Pope, on condition of holding it from the holy see. This prince was the first of the French monarchs who made dignities and honours hereditary; he died by poison, after a weak and inglorious reign, A.D. 877. During his reign, the Normans, who had first made their appearance in France in 843, sailed up the Seine, and burned Paris.

Charles the Bald was succeeded by his son Louis the Stammerer, who, after reigning only about two years, died in 879, leaving his queen Adelaide pregnant. He was succeeded by Louis III., and Carloman II., his two sons by a former marriage. On the death of these princes, in 884, the Emperor Charles the Fat, son of Louis the German, was elected king of France. He disgraced himself, by ceding Friesland to the Normans; but this cession was not only disgraceful, but impolitic, for it served only as a fresh incentive to depredation. Paris was attacked a second time, but gallantly defended by Count Eudes and Bishop Goslin. A truce was concluded, but the Normans, after leaving Paris, besieged Sens and plundered Burgundy. During these transactions, Charles was deposed by an assembly of the states, who conferred the crown on Eudes. His title to the throne, however, was never acknowledged by a great part of the states of France, who, on the contrary, gave their allegiance to Charles the Simple, son of Louis the Stammerer, by Adelaide. During a reign of ten years, Eudes manfully withstood the Normans.

After the death of Eudes, in 898, Charles succeeded to the throne of France; but his reign was by no means tranquil, the nobles aspiring openly to independence, and depressing the great body of the people. In the midst of these internal disorders, the Normans gained a permanent footing in France; Rollo the Norman, in 912, compelling the king to yield him a large portion of the territory of Neustria, and to give him his daughter in marriage. The new kingdom was called Normandy, of which Rouen was the capital. In the same year, the empire of Germany was separated from France, by the death of Louis IV. son of the Emperor Arnold. Charles the Simple being equally contemptible to the French and the Normans, was deposed in 922, and Robert, Duke of France, brother to Eudes, proclaimed king. Robert, however, was soon afterwards killed in battle. His son, Hugh the Great, instead of assuming the sovereignty, placed the crown on the head of Rodolph, Duke of Burgundy, who assumed the title of king, and was almost universally acknowledged. In this extremity, Charles endeavoured to gain the assistance of the Duke of Normandy, and the Emperor of Germany; but being betrayed, and thrown into prison by the court of Vermandois, he died there in 929.

After his death, Rodolphe being now indisputed master of France, acted with great decision and vigour. He repelled the incursions of some new tribes of Normans, restrained the licentiousness of the nobles, and restored tranquillity to his kingdom. He died without issue, in 936. An interregnum ensued, and France was again involved in troubles. At last Hugh the Great, still ambitious of sovereignty himself, recalled Louis the son of Charles, who had taken refuge in England: from this circumstance he was surnamed the Stranger.

When Louis was called to the throne he was only 17 years old, and was little acquainted with the affairs of France, or the manners of the people. Notwithstanding these disadvantages, he conducted himself with considerable propriety, though with a portion of spirit rather creditable than useful to him; for, not liking the tyranny of Hugh, who had been his tutor, he made a fruitless attempt to rescue himself from this bondage; but, after a variety of struggles, he was compelled to make peace with his vassals, and to confine to him the county of Lorraine, which comprehended almost the whole of the royal domain.

Louis the Stranger died in 954, and left his son Lothario only a shadow of royalty; for, though Hugh the Great died in 955, he was succeeded in consequence, abilities, and influence, by his son Hugh Capet, soon destined to be on the throne of France. Lothario died in 986, and was quietly succeeded by his son Louis V., who governed, under the direction of Hugh Capet, during a short reign of one year and two months. In him ended the Carolingian race of kings, A.D. 987.

Hugh Capet being the most powerful nobleman in
France, seized the crown on the death of Louis V.; and, as he possessed the dukedom of France, which extended as far as Touraine, and was also count of Paris, and in possession of large territories in Picardy and Champagne, while the royal domain was reduced to the cities of Leon and Soissons, he in fact brought more strength to the crown than he derived from it. Though the right of succession belonged to Charles, Duke of Lorraine, uncle to Louis V., yet Hugh Capet, by his power, and by securing the favour of the clergy, was acknowledged in an assembly of the nobles, and was afterwards anointed at Rheims. In order to establish the throne in his family during his lifetime, he associated his son Robert in the government of the kingdom, and prudently vested him with those insignia of royalty which he denied himself, lest he should displease those who had been very lately his equals. The Duke of Lorraine did not give up his right to the crown of France without a struggle; but, being defeated, he was made prisoner by Hugh Capet. In 996 this monarch died, and was quietly succeeded by his son Robert. This prince had married Bertha, his cousin in the fourth degree; but though this marriage had been authorised by the bishops, Pope Gregory V. undertook to dissolve it, under the pretence that it was within the forbidden degrees of consanguinity. Robert, however, persisted in keeping his wife, and was on this account excommunicated. Such was the effect of the excommunication, that he was abandoned by all his courtiers and his servants, except two, who threw to the dogs all the victuals their master left, and purified by fire the vessels in which he had been served. The king, alarmed either at his spiritual punishment, or at the commencing commotions in his kingdom, at last divorced his wife, and married Constance, daughter to the Count of Arles. The last years of his reign were rendered very unfortunate by the disorders of his family. His eldest son Hugh, whom he had associated in the sovereignty, was dead; and Constance, who was an imperious temerity of the reign was thus humbled, and Henry recovered his power, but at the expense of part of his dominions, which, out of gratitude, he made over to the Duke of Normandy.

Soon after Henry was restored, the Duke of Normandy made a pilgrimage to Jerusalem; and, dying before his return, there was a dispute concerning the succession to his dominions. His natural son William had been recognised by the nobles, before the departure of Robert; and his guardianship was entrusted to the King of France and the Duke of Bretagne. As soon as the death of Robert was known, the Norman nobles broke out into personal quarrels, which the Duke of Bretagne in vain endeavoured to appease. Under these circumstances, the King of France had an excellent opportunity of displaying his gratitude for the favours which he had received from Robert; but he seemed rather willing to deprive his infant son of his inheritance, by invading Normandy. Not finding, however, the conquest so easy as he expected, he resumed the appearance of friendship and generosity, united his forces with those of the young Duke, and the malcontents were totally routed in the battle of Val de Dunes, A.D. 1016.

In 1066, Henry I. was succeeded by his son Philip I.; Philip I. and about six years afterwards, William, Duke of Normandy, successfully invaded England. Philip was only eight years old when his father died, and remained under the guardianship of Baldwin V., surmounting the Pious, Count of Flanders, a man of strict honour and integrity, till the year 1067, when Baldwin died, having, just before his death, concluded an offensive and defensive alliance between the crowns of Scotland and France. Philip incurred the excommunication of Urban II. by his marrying Bertrand de Montfort, Duke of Anjou, while his husband and his queen were both alive; nor was the excommunication taken off till the death of the Pope and the Queen in 1097. Philip, however, though relieved from his domestic troubles, was exposed to the rapacious power of his nobles, who insulted him constantly, and cut off entirely the communication between Paris and Orleans. In order to remedy these evils, Philip associated with him his son Louis. This prince was active, vigorous, generous, affable, and free from most youthful vices. He soon perceived the full extent and the exact nature of the dangers which surrounded him, and that nothing could be accomplished by force. He therefore kept continually in the field with a small body of troops about him, whom he employed against such nobles as would not listen to the dictates of justice and equity; he demolished their castles, and laid waste their ground; and by these measures, and by compelling them to render restitution to those whom they had pillaged, he restored order to the state, preserved the monarchy from subversion, and gained the affections of the virtuous part of the nobility, and the reverence of the people.

In 1108, when he was 50 years old, he succeeded his father. From his great size in the latter part of his life, he was called Louis the Gross. Soon after his coronation, he engaged in a war with Henry I. of England, the particulars of which will be found in our history of that kingdom. After the peace between these monarchs, which took place A.D. 1128, Louis devoted himself to the regulation of the internal management of his kingdom. He re-established the commons, or third estate, which had long ceased to exercise its privileges; he enfranchised the villains, or bondsmen; diminished the authority of the seignorial jurisdictions, and sent commissaries into the provinces to receive complaints, redress wrongs, and encourage appeals to the royal judges. In the midst of these wise regulations, his excessive vileness brought on a disorder which terminated in his death, in the 60th year of his age, and 30th of his reign, A.D. 1137.

Louis VII., surnamed the Young, to distinguish him from his father, was 18 years of age when he ascended the throne. He was of a devout turn of mind, good-natured, and easy in his temper; but jealous of his lo-
The chapter of Bourges, having chosen an archbishop disagreeable to the count, he ordered them to choose another; but the chapter was supported by Pope Innocent II., who insulted the king, by calling him a young man, whom it was necessary to instruct that he had no right to interfere in the affairs of the church. Louis, however, remained firm; and his kingdom was placed under an interdict. Thibaut, Count of Champagne, had declared himself for the archbishop confirmed by the Pope, and thus gave rise to a civil war. Louis made himself master of Champagne, and set fire to the church of Vézelay, into which the inhabitants of that town had fled for refuge. The effect of this was strongly impressed on the king's mind, not only on account of the number of lives which were lost, but also on the sacrilege which he had committed; and he made a vow to visit the Holy Land, in order to expiate his crime. To this project he was further incited by Bernard, abbot of Clairvaux, who had been selected by Pope Eugenius III. to preach a crusade. In the market place of Vezelay in Burgundy, Louis was seen by the side of Bernard, seconding the exhortations of that monk for the nobles and peasantry to take the cross, both by his harangues and his example. In vain did Seiger, abbot of St Denis, a man of sound sense, and wonderfully free from the mad enthusiasm of the age, endeavour to dissuade Louis from this enterprise. He foretold the inconveniences that would result from it, and the danger to which the king would be exposed; but Bernard, on the other hand, made himself answerable for its success, and extolled it with an enthusiasm that passed for inspiration. Before his departure, however, the king had the good sense to name Seiger minister to the regent, whom he left in charge of the kingdom.

Such was the rage for the crusade in France and Germany, at this period, that Louis reckoned in his army 70,000 men in complete armour, with a very great number of light horse, besides infantry; but this force, though doubled by what the Emperor of Germany brought along with him, was rendered of little or no benefit to the cause in which they were engaged, by its very numbers, and by the total want of order and discipline. The Emperor of Germany fell into a snare set for him by the Sultan of Iconium; and the same misfortune soon afterwards befell Louis. He met likewise with another calamity still more grievous, and which gave him more uneasiness than the loss of his army; for his queen Eleanor, whose affection and zeal led her to embrace the cross, and accompany him into Asia, was suspected of an amour with the prince of Antioch. His marriage with her had been entered into contrary to the advice of Seiger; and, after the death of that minister, Louis, convinced of the soundness of his opinion by the conduct of his wife, divorced her, and restored to her the provinces of Guienne and Poitou, which he had received with her in marriage. Eleanor, soon after her divorce, married Henry Plantagenet, Duke of Normandy, who, the following year, became King of England, under the name of Henry II. The remainder of Louis's reign presents nothing worthy of notice. He frequently quarrelled with Henry II. of England; but their quarrels were soon made up. In 1179, he made his son Philip, who was then 14 years old, be crowned at Rheims; and the following year he died of a paralytic stroke, at the age of 60.

Philip II., who was afterwards surnamed Augustus, on account of his exploits, had as his guardian the Count of Flanders. He signalized the commencement of his reign by confiscating the property of the Jews in France, and banishing them from the kingdom. He next turned his attention to the improvement of Paris, which he enlarged and paved. It was soon apparent, that Philip was by no means disposed to suffer his authority to be tampered with or curtailed, even by the clergy; for, on an emergency, finding it necessary to raise some troops, he demanded a subsidy from the clergy of Rheims; they refused the subsidy, but offered their prayers for his success. Soon afterwards, their territories were laid waste by some of the neighbouring nobles, and they applied to the king for succour; but his reply was, that he would use his intercessions to these nobles to respect the territory of the church. He did so, but they continued their ravages; and at length the clergy found themselves under the necessity of complying with the demand of the king, in order that they might obtain his assistance against their invaders. Philip next turned his attention to the extinction of the brigands, who, under the name of Roturiers, infested France, setting at nought both the civil and ecclesiastical power. In one battle he destroyed 7000 of them.

The quarrels which had existed between Philip's father and the King of England still existed; Philip exasperating Henry's sons in their undutiful behaviour towards their father. But the quarrels being in some degree quieted, by the death of Henry's two most rebellious sons, the monarchs assumed the cross, and prepared for the Holy Land. This enterprise, however, was surrounded with great obstacles. Philip still jealous of heresy, entered into a private confederacy with Richard, now heir apparent to the throne of England, and Henry found himself obliged, at an advanced age, to defend his dominions against France and his own son. Being unsuccessful, he engaged to pay Philip a compensation for the charges of the war. Notwithstanding this success, however, Philip felt himself relieved by the death of Henry, which took place A.D. 1189. The project of a holy war was again entertained. Both Philip and Richard King of England partook of the superstitious prejudices and zeal of the age, and they both were ever after military glory. Thus they expected to satisfy both their religious and their military feelings, by an expedition to the Holy Land. As, however, former attempts had been so unsuccessful, it was necessary to try another road; and they accordingly resolved to conduct their armies by sea, to carry their provisions along with them, and by means of their naval power, to preserve an open and regular communication with their own states, and with the western parts of Europe. On the plains of Fezeli, in Burgundy, the monarchs assembled their armies, which amounted to 100,000 men. After renewing their oaths of friendship, and pledging their faith not to invade each other's dominions during the crusade, they separated, Philip taking the road to Genoa, Richard to Marseilles. From these parts, they both put to sea; and both were compelled by a storm to take shelter in Messina, where they were detained the whole of the winter A.D. 1190-1191. The siege and capture of Acre was the sole fruit of this immense expedition. Philip fell sick, and returned to France. Richard remained some time afterwards; and on his return, having been made prisoner in Germany, the French king, forgetful of his oath, endeavoured to profit by the absence of
Richard, and entered into a treaty with John, his perfidious brother. As soon as Richard recovered his freedom, he turned his thoughts towards vengeance on Philip. But the latter gained several advantages over his opponent; and these two princes continued to harass each other, till the death of Richard, A.D. 1199. John, who succeeded to the throne of England, having refused to appear as a vassal of France, to answer for the death of Arthur of Bretagne, all his territories that were situated in that kingdom were confiscated by Philip, who took possession of Normandy, and united it to his crown. Touraine, Anjou, and Maine, were also wrested from John, so that nothing remained to him, but Guienne.

In 1213, Philip was chosen by the Pope to carry into execution the sentence of excommunication pronounced against John; and as a reward, he was to receive the remission of all his sins, endless spiritual benefits, and the kingdom of England. Philip accordingly levied a great army, and prepared for the invasion of England. Nor was John idle or unprepared. But while Europe was in expectation of a dreadful contest, the Pope persuaded John to hold his dominions as a feudatory territory of the Church of Rome. Philip was enraged at being thus duped: his fleet put to sea, but it was utterly destroyed by that of England; and John was strengthened by an alliance with the Emperor Otho IV. At Rouenisis, a small village between Lisle and Tournay, the Emperor’s army, amounting to upwards of 50,000 men, was met by that of Philip, which was rather inferior. A dreadful battle was fought; the Emperor and his allies were routed, and 30,000 Germans are said to have been slain. After this victory, Philip entered Paris in triumph; the Counts of Flanders and Boulogne, his prisoners, gracing the ear of the conqueror.

In 1215, the Barons of England, dreading the total loss of their liberties, their possessions; and their lives, in consequence of the proceedings of John, offered the crown to Louis, the eldest son of Philip. Louis accepted the offer; landed in England; but disgusted the people by his partiality to his own countrymen, so that, on the death of John, and the Barons agreeing to acknowledge the authority of his son Henry III. Louis was obliged to return to France. Soon after his return in 1223, Philip died, leaving the kingdom of France twice as large as he had received it.

Louis VIII. reigned but about three years, the greatest part of which was chiefly spent in a crusade against the Albigenses. He was succeeded, A.D. 1226, by his son Louis IX., commonly called Saint Louis, then only 12 years of age. Blanche of Castile, the Queen-mother, had been appointed regent; and during the minority of her son, she repressed the ambition of the powerful and turbulent barons, by her prudence and firmness. As Louis advanced to manhood, his singular character developed itself. He was infected with a mean and abject superstition, yet endowed with a large portion of courage and magnanimity. His justice and integrity were conspicuous; and where superstition did not turn him aside from the bent of his natural inclination, he was mild and humane. But the barbarous devotion of the times led him often astray. He favoured the tribunal of the Inquisition, persecuted heretics, and considered a war against the Infidels as the most meritorious action he could perform. This turn of mind was strengthened by a dangerous illness with which he was attacked; for his heated imagination made him fancy that he heard a voice from heaven, commanding him to shed the blood of Infidels. Accordingly, he made a vow to take the cross, and spent four years in preparing for his expedition. He entrusted the government of the kingdom to the care of his mother; and at last, every thing being arranged, A.D. 1248, he sailed for Cyprus, accompanied by his queen; his three brothers, and almost all the knights of France. From this island, he proceeded to Egypt, instead of going directly to the Holy Land; and, in 1249, he landed with his army near the city of Damietta. Soon afterwards, having received a reinforcement from France, his army amounted to 60,000 men. But this expedition was as unfortunate as those which had preceded it. Nearly half the French troops fell a prey to sickness and debauchery. The rest were defeated by the Sultan of Egypt at Massoura, where Louis, two of his brothers, and all his nobility, were taken prisoners; his third brother having been killed by his side. The Queen of France had been left in Damietta; this place was besieged, but it made a gallant defence, till a treaty was concluded with the Sultan, by which it was given up in consideration of the king’s liberty; and a large sum paid for the ransom of the other prisoners. Louis, notwithstanding all chance of success had long been at an end, was still so bent on fulfilling his vow, that he set out for Palestine, where he remained four years, without being able to accomplish any thing. In the mean time, the affairs of France were in the greatest disorder, in consequence of a monk having collected upwards of 100,000 men, under the pretence of leading them to the assistance of their sovereign. This multitude robbed and pillaged wherever they came; nor were they dispersed without considerable difficulty. In 1258, the Queen-mother having died, Louis returned to France, where he repaired the evils occasioned by his absence, and atoned for the folly of his crusade, by his zeal for justice, his wise laws, and his virtuous example. He established, on a more solid basis than before, the right of appeal to the royal judges; prohibited private wars; substituted juridical proofs, instead of those by duel; and restored France from the exactions of Rome. In his transactions with other sovereigns, he was also highly praise-worthy, and consulted the real interests of his own kingdom, while he behaved with justice and moderation towards them. He invaded Roussillon and Catalonia to the King of Aragon, in exchange for the claims of that monarch to some fiefs in Provence and Languedoc, and persuaded the King of England to renounce all claim to Normandy, Maine, and other forfeited provinces, by restoring to him Querci, Perigord, and the Limosin. Such was his moderation, that he was chosen, A.D. 1264, arbiter between the King of England and his barons; and his sentence, though rejected by Leicester and his party, was undoubtedly that of justice as well as wisdom. In one instance he was deserted by his love of justice. He permitted a crusade to be preached in France against the King of Sicily, in behalf of his brother, who had no right to that throne. Soon after this, A.D. 1270, he prepared for another holy war. His object was now the conquest of Tunis, or the violent conversion of its sovereign to Christianity. The Infidel rejected the alternative: but the French army, soon after its landing, was seized with an epidemic distemper, of which Louis himself, and one of his sons, as well as numbers of his troops, were the victims, A.D. 1271.
Philip III. surnamed the Hardy, succeeded to the throne when he was 25 years old. Had it not been for the assistance afforded him by his uncle, Charles of Anjou, he would have found it impossible to have extricated himself and the remnant of his army from the Infidels; but he having defeated them, concluded a peace for his nephew, on the favourable conditions that the King of Tunis should pay him a large sum of money; Charles himself the ancient tribute due to him as King of Sicily; that the Christians in Tunis should enjoy the full exercise of their religion; and that the prisoners on each side should be exchanged. Little of moment occurred after Philip's return to France. In 1274, he declared war against Alphonso of Castile, on the subject of the succession to that crown; but the war soon terminated without producing any event of consequence. Philip's character led him frequently to engage in enterprises with great acacity and zeal; but he had not sufficient firmness to persevere in them. He was much under the influence of the Pope; and to him the papal government was indebted for the Venaisir, which they retained till the Revolution.

Philip naturally took great interest in the affairs of his uncle, Charles Duke of Anjou, King of Sicily. And this leads us to notice the Sicilian Vespers. The inhabitants of Sicily, when Charles governed with more strictness than policy, resolved to rid themselves entirely of the French. They were farther excited to revolt by Peter III. King of Arragon, who laid claim to the throne of Sicily, and promised the Sicilians his assistance to expel the French. On the evening of Easter day, A.D. 1282, the massacre began. Not a Frenchman was spared. Peter arrived; was crowned at Palermo, and Charles was compelled to abandon the island. The Pope, however, embraced the side of the latter; excommunicated Peter, and gave his kingdom to Charles the second son of Philip. The King of France immediately prepared to establish his son on his new throne by force of arms; but he was not successful, and in 1285, as he was returning from this expedition, he died at Perpignan. Letters of nobility were first used in France during this reign. They were granted to Raoul, a goldsmith. This, however, was only a restoration of the old custom of the Franks, who were all esteemed equally noble. A distinct and privileged nobility first arose at the close of the second race of kings.

Philip was succeeded by his son Philip IV. surnamed the Fair. The first object of this monarch was to compose all differences with his neighbours. To this step he was led by the derangement of his finances. Although in thus settling his differences, he was much indebted to Edward I. of England, yet he ungratefully, as well as impolitically, soon afterwards engaged in hostilities with him; and he also rashly attempted to gain possession of Flanders, which had joined England. But in this enterprise he was unsuccessful; though it cost him much blood and treasure. These events, however, were of trifling moment, compared to the quarrel between him and the Pope Boniface VIII. a man of a turbulent disposition, arrogant, and overbearing. He had prohibited the clergy from granting any aids. But Philip, being equally determined to support his own power, and being moreover very poor, resolved that the clergy in France should contribute, equally with his other subjects, to the exigencies of the state; and he resolved not only on this, but also forbade them to send money abroad without his permission. This gave rise to the quarrel between Boniface and the king. The former was by no means disposed to yield; on the contrary, he appointed as his legate to the court of France, Bernard Saissette, who had rebelled against the king, and who on this, as well as on account of his disposition, Boniface must have known would be particularly obnoxious to him. This legate fully acted up to the orders of his master; he bravely Philip at his own court, and threatened him with an interdict. Philip was so much under the influence of superstition, or so afraid of the impression it might make on his subjects, that he did not bring the legate to trial, but contested himself with delivering him into the hands of his metropolitan. On this the Pope, enraged, issued a bull, declaring that the Vicar of Christ is vested with full authority over the kings and kingdoms of the earth; and at the same time, the French clergy were ordered to repair to Rome. Philip commanded the bull to be commuted to the flames, and the bishops not to leave France; and he seized the possessions of those who did leave it. In this state of things, he had recourse to a most politic measure. He assembled the states of the kingdom, and they disavowed the claim of the Pope, and recognised him as an independent sovereign in his own kingdom. Having proceeded thus far, Philip resolved to wage open war against Boniface; but the Pope was not intimidated. He displayed great coolness and courage. Having been insulted, however, in his own territories, by a band of desperadoes hired at the instigation of Philip, he was so much affected that he died in a few days. Benedict XI. his successor, a mild and good man, took the interdict off Philip; but this Pope was too good and wise for the age in which he lived. He was taken off by poison A.D. 1303; and his successor Clement V. being a Frenchman, and entirely in the interest of France, fixed his residence in that kingdom. Philip being now at peace, turned his attention to the internal affairs of his kingdom. Supreme tribunals, called Parliaments, were instituted, and the commons, or third estate, were formally admitted into the assemblies of the nation. So far his measures were wise and popular; but, in what regarded the finances, they were of an opposite character. The royal treasury was exhausted; and, to remedy this evil, the nominal value of money was raised. The dilapidation of his finances led the king also to adopt another measure still more unjust. The Knights Templars, a religious and military order, had acquired large possessions in almost every part of Europe, but especially in France. In consequence of the severity of the taxes which Philip levied, a sedition arose in Paris; the Knights Templars were accused of having fomented it; orders were issued that they should all be committed to prison in one day; and absurd and enormous crimes were imputed to them. They were put to the rack; confession extorted, or forged confessions imputed to such as were firm; and at last Philip succeeded in destroying most of them, and in obtaining possession of their riches. Soon after this disgraceful proceeding, A.D. 1314, Philip again unsuccessfully attempted to unite Flanders to the crown of France; and his death is supposed to have been in a great measure occasioned by his failure.

He was succeeded by his son Louis XI., surnamed Louis the Hunt, who was scarcely seated on his throne when he ordered his prime minister Marigny to be executed, under the pretence of his being guilty of magic, but, in reality, that he might gain possession of his wealth,
Louis, however, being improvident, soon spent the money he had thus unjustly acquired; and he was obliged, to satisfy his wants, to extort money from the nobility; to levy a tenth from the clergy, to sell their liberty to the slaves who belonged to the royal domains; and even to compel such of them to be free as wished to continue slaves. Thus the king’s avarice, or prodigality benefited his subjects. It is remarkable that the edict of enfranchisement, dated 3d July 1315, declares that every person is born free by nature. The following year this monarch died, in consequence it is said of having taken ice when he was warm: it is suspected, however, that he was poisoned.

He was succeeded by his brother Philip V. sur-named the Long, on account of his remarkable stature. It was on occasion of this succession that the Salic law was recognised and enforced by the states of the kingdom; for Louis having left one daughter by his wife Margaret of Burgundy, the Duke of Burgundy wished to support the claims of his niece: the states, however, having been assembled, excluded her, and declared all females for ever incapable of succeeding to the throne of France. This reign presents no foreign affairs of any moment; but it may be noticed, that during it the Jews were banished, being suspected, or rather accus-san for (it is probable that they were not even suspected, much less proved guilty) of having poisoned the wells and fountains at the instigation of the kings of Tunis and Grenada. Philip excluded the bishops from the parliament, where they had possessed too great authority. He also obliged the burgurers to deposit their arms in the arsenals, whence they were not permitted to take them, except in case of war. He likewise appointed their officers, and established a numerous militia. In another enterprise he was not successful: for he in vain attempted to establish, over all his kingdom, the same denominations of money, weights, and measures. In the midst of these projects, he died A.D. 1322.

He was succeeded by his brother Charles IV. named the Fair. This prince, immediately on his accession, turned his attention to the finances, in the management of which there were many abuses. At this period, the Italians in every part of Europe had almost entire management of money concerns; and Charles having discovered that they were guilty of extortion, as well as dishonesty, confiscated their property, and put some of them to death. During this reign, a short war took place between France and England, respecting a castle which Edward II. pretended belonged to him: but, in 1326, Edward III. having succeeded to the throne of England, peace was concluded between the two monarchs. Charles the Fair died in 1328, leaving the kingdom loaded with debts. He was the last of three brothers, successors of Philip the Fair, all of whom died in a short space of time.

Charles left only one child, a daughter, who of course could not succeed him; but as his queen was pregnant at the time of his death, Philip de Valois, the next male heir, was appointed regent; and, on a daughter being born, was unanimously placed on the throne of France. Though his title was indisputable, yet Edward III. of England put in his claim; and this gave rise to the most memorable events in the history both of England and France, for upwards of a century. As these, however, have been noticed in the History of England, they shall be but very briefly narrated here. As the contest for the throne of France was one of very great importance, and likely to be long and arduous, both the competitors endeavoured to strengthen themselves by alliances. In 1346, Edward invaded France with an army of 30,000 men, and Philip advanced to meet him at the head of 100,000. On the 26th of August, in that year, the famous battle of Cressy was fought, in which the French were defeated with great slaughter. In 1347, Edward took Calais; and in the following year, he returned in triumph to England, having concluded a truce with France. In the midst of his misfortunes, Philip had the satisfaction of seeing Dauphiny annexed to the crown of France, the last Count of that province dying without issue; having ceded his territories to the crown of France, on the condition that the eldest son of the French monarch should assume the name of Dauphin. Philip died in 1350, at the age of 57, worn out with distress and anxiety. During his reign, a change took place in the constitution of the parliament, by the incorporation of the counsellors named jureurs, who had formerly been taken exclusively from the noblesse, and the counsellors named rapporteurs, who had been taken from the class of citizens. It was also in this reign that the famous tax on salt, the gabelle, was imposed, or rather established and augmented.

John, the eldest son of Philip, succeeded to the throne; but an act of injustice towards the Constable Raoul, whom he ordered to be beheaded without any form of trial, rendered him soon very unpopular. Of this, and of other circumstances, Edward III. took advantage; for Charles, King of Navarre, setting up a claim to the throne of France, Edward resolved to support him. In this emergency, John convoked the states-general in 1355, who agreed to a levy of 30,000 lancers, besides 100,000 other troops, and to a subsidy to support them. At this assembly, a decree was passed, that no proposition should be admitted without the unanimous consent of the three branches or their deputies. Thus, the third estate, which hitherto had been too much and too often the slaves of the nobility or clergy, obtained their due share of authority. In 1355, Edward invaded France again, and sent into Guienne the Prince of Wales, who had gained so much fame at the battle of Cressy. On the 19th of September in the following year, this prince was again successful, at the battle of Poictiers, in which the French were completely defeated, and their king taken prisoner. John was treated with great attention and generosity by his captor, who, having concluded a truce for two years, brought him over to England. In consequence of the captivity of their monarch, the people of France were plunged into the greatest disorder and confusion. The Dauphin, indeed, assumed the management of affairs, but his authority and influence were not sufficient to restore tranquility; and, as he was totally destitute of supplies, he found himself under the necessity of convo-ning the national assembly; but that body, instead of supporting his administration, seized the opportunity to demand limitations of the regal power. Paris itself was entirely under the domination of the provost of the merchants: the dauphin was detained in a kind of captivity. In the midst of these disorders, the King of Navarre, who had been thrown into prison by John in the year 1355, contrived to escape, and put himself at the head of the malcontents; but his conduct was so at-rosious, that even those who had previously favoured his claims, now forsook him, and resolved to strengthen the power of the dauphin. For this purpose they rallied round him, and the provost of the merchants having been slain in an attempt to deliver Paris up to the
After considerable but he never abandoned them, and the French army met with no resistance at A.D. 1360, so that he invaded France with the whole military force of England. In 1360, he concluded an advantageous treaty of peace with his prisoner King John, who thus obtained his liberty. On his return to France, however, finding that his nobility were by no means disposed to allow him to fulfil his engagements, he voluntarily came back to England, where he died at his lodgings in the Savoy, 1364.

John was succeeded by his son Charles V, surnamed the Wise, an epithet which he well deserved, by the prudence and policy of his conduct: his first care was to repair the losses which his kingdom had sustained from the errors of his predecessors: and having been made too sensible that the recent calamities of France had, in a great measure, sprung from the captivity and absence of the monarch, he formed a resolution never to appear personally at the head of his army. Charles was resolved to render France, if possible, a match for England; but, in order to do this, it was necessary not only to restore tranquillity, and to introduce order and economy into all his internal arrangements, but also to bring under subjection, or weaken the King of Navarre, who, from the vicinity of his dominions, had it in his power always to prove a restless and formidable opponent. Against him, therefore, he first turned his arms; and he soon, principally by the valour of Bertrand de Guescin, one of the most accomplished captains of the age, obliged him to sue for peace, A.D. 1365. He next settled the affairs of Bretagne. Thus having succeeded in these enterprises, he turned his attention to the immense number of military adventurers, who, having followed Edward into France, had, under the name of Companies, become a terror to the peaceable inhabitants; these Charles soon found were too numerous and formidable to be reduced by force; he therefore had recourse to policy. Alphonso XI, King of Castile, was succeeded by his brother Peter I, surnamed the Cruel; against him, Henry, Count of Trastamara, took up arms; but being obliged to flee into France, he obtained permission from Charles to instil the companies in his service. They readily embarked in an enterprise which promised them employment and booty; and thus Charles freed his kingdom of these adventurers. As soon as Charles was satisfied of the internal peace of France, he directed his thoughts to the reformation of the coin: he likewise lessened the taxes, encouraged agriculture and commerce, and embellished his capital. In the midst of peace, however, he was still preparing for war, and anxious to wipe off the disgrace which the successes of England had inflicted on the arms of France. An opportunity soon presented itself: the inhabitants of Guienne, oppressed by the taxes of the Prince of Wales, to whom that province had been given by his father, laid their complaints before the King of France. The Prince of Wales was cited to appear and answer these complaints: he answered that he would certainly come to Paris, but it should be at the head of 60,000 troops: but he was no longer that Black Prince, who performed even more than he threatened; he was worn out both in body and mind by sickness. In 1360, war was declared. The French were successful. Charles, relying on his superiority, pronounced a sentence of condemnation against the Prince of Wales for his contumacy in not appearing when cited; declared him and his father rebels; and confiscated all their territory in France. In a few years, the English were stript of all their ancient possessions in that kingdom, except Bourdeaux and Bayonne, and of all their conquests except Calais. Charles died in 1380, after a reign of great glory and benefit to his subjects. With respect to his domestic life, there are some curious particulars recorded: he always rose at six o'clock; and having performed his private devotions, as well as attended mass, he gave audience to all who presented themselves, rich and poor, receiving their petitions, and reading them himself: at 10 o'clock he dined, spending but a very short time at table, and eating only of one sort of dish; he always diluted his wine with a considerable portion of water. During dinner, he was instructed by the discourse of some wise and virtuous man. After dinner, he gave audience to the foreign ambassadors; he next admitted his ministers, and learned from them the state of the kingdom. At one o'clock, he retired into his chamber and repose himself; an hour afterwards, his chamberlains entered and entertained him with light conversation; at three he attended vespers, and afterwards walked in his garden. On his return, the queen brought in his children, whom he interrogated respecting their progress in education. In winter, instead of walking, he employed himself in reading the Holy Scriptures. He took little supper, and went to bed early. Though he spent his time at home in this plain and simple manner, he always appeared abroad with a considerable degree of dignity and splendour: before his subjects he was always a king. His dress was magnificent; his gendarmes preceded him; his squires carried his ermine mantle, his sword, and his regal hat: he walked always by himself, his brothers and the princes of the blood following him at some distance. He seems to have been fond of literature, and no present was more acceptable to him than books. King John had left only 20 volumes in the royal library; he increased them to 900. In the year 1370, Charles, in order to rouse his subjects to feats of arms, forbade all games of hazard, and substituted in their place exercises with the common and the crossbow. By another ordinance in the following year, he granted letters of nobility to all the citizens of Paris. This privilege they enjoyed till 1577, when it was restricted to the provost of the merchants, and a few others. It was entirely suppressed in 1667, and re-established in 1707; and again suppressed in 1715.

Charles the Wise was succeeded by his eldest son Charles VI. A.D. 1380. Charles VI, a minor: a few years before his death, Charles thinking it probable that he should leave his son very young, passed the ordinance, which fixed the majority of the French King at the age of 15. Charles VI, when he mounted the throne, was 15. His uncle, the Dukes of Anjou, Berne, and Burgundy, differed respecting the regency; but it was settled by those to whom they referred their difference, that the king should be crowned in a few months, and that in the interval he should govern in his own name, but with the advice of his uncle. Till the coronation, the Duke of Anjou seems to have had the principal management of affairs, but he employed his authority rather for his own advantage than for the benefit of the king and the people. Charles did not assume the sovereignty till the death of the Duke of Anjou in 1388: at first, it was hoped that he would prove a man of spirit and enterprise; but he soon fell into a fit of frenzy; and though he recovered, he was unequal to the government of the kingdom, on
account of his frequent relapse, and his general imbecility. His first relapse was occasioned by a singular incident. At a masquerade, he, with some of his nobles, covered their bodies with rosin, powdered over, while hot, with fur. The combustible habit of one of them was accidentally set on fire: the flames communicated to some of the others, and the king was so much affected by the fright, and his narrow escape, that his disorder returned, and it afterwards generally attacked him four or five times a year to the end of his life. It is scarcely possible to conceive a court more profligate and debauched than that of France at this period. While things were in such a situation, the Duke of Burgundy died. He was succeeded by his son, who hoped to govern France as his father had done, during the illness of Charles; but he was opposed by the Duke of Orleans, the king's brother, who relied for his authority, not so much on his relationship, as on the influence which the duchess had over Charles's mind, even in its most violent and disordered state. The quarrels between the two Dukes were carried to a great height; but at last, A.D. 1407, by the interposition of common friends, they were persuaded to enter into a league of amity, in the most solemn manner. But the Duke of Burgundy was meditating treachery, even while he was professing friendship; for he hired ruffians, who assassinated his rival in the streets of Paris, and when the ruffians gave him as their instigator, he avowed and justified the action. What is still more strange, the parliament of Paris passed over the crime, and even seemed to admit the Duke of Burgundy's justification. The consequences were such as might have been anticipated: The princes of the blood, combining with the young Duke of Orleans and his brothers, made war against the Duke of Burgundy, and the unhappy king was a prisoner, sometimes with one party and sometimes with another. The provinces were laid waste; assassinations were frequent; and law, order, justice, and humanity, were equally set at nought. Each party endeavoured to strengthen their adherents by every mode in their power, and the fraternity of butchers in Paris having declared for the Duke of Burgundy, the adherents of the Duke of Orleans made interest with the carpenters;—the fate of the capital depending on the prevalence of either party.

During this calamitous state of France, England remained from invading her, till Henry V. ascended the throne; but soon after his accession, he landed in Normandy at the head of 50,000 men: the battle of Agincourt followed, in which the French were defeated with great slaughter. Notwithstanding his success, Henry was obliged to return to England for a supply of men and money. In the mean time France was exposed to all the ills of civil war. The Duke of Burgundy, who had been worsted by his antagonists, attempted to regain possession of his power and of the person of the king; and these objects he was enabled to accomplish, in consequence of some quarrels in the royal family; the person of the king was seized by him; the dauphin made his escape with difficulty; and great numbers of the opposite faction were butchered. By this time Henry was again in a state to revisit France with a large force; he landed in Normandy and carried everything before him; afterwards he concluded the treaty of Troyes, with the Queen and the Duke of Burgundy, by which the succession to the throne of France was secured to the King of England, and he received the princess Catherine in marriage, A.D. 1420. As soon as the dauphin heard of this treaty, he assumed the style and authority of regent, and appealed to God and his sword for the maintenance of his title; but being unequal to his adversary, he was obliged to avoid a battle. In less than two months after the death of Henry V. A.D. 1422, Charles VI. terminated his unhappy life; and the dauphin was crowned at Poitiers, (Rheims being in the possession of the English) under the name of Charles VII.

This sovereign was very popular in France; and the situation of that kingdom required the exercise of all his talents, and the influence of all his popularity. On the other hand, the Duke of Bedford, the regent during the minority of Henry VI. was a man of great talents and prudence, and fully sensible of the difficulty of preserving a newly acquired kingdom against the legitimate sovereign, so well beloved as Charles was. At first, the Duke of Bedford was successful. He defeated the French, and their allies the Scots, in 1424, in the battle of Verneuil; but his next enterprise was destined to reduce the ruin of the English, and their expulsion from France, by means so extraordinary, as in that age universally to be deemed miraculous. In 1428, the Duke of Bedford undertook the siege of Orleans. The affairs of Charles seemed desperate. He entertained thoughts of retiring into the remote provinces of his kingdom, where the influence of his Queen, Mary of Anjou, and of his mistress, Agnes Sorelle, who lived in perfect amity with the Queen, changed his mind; and he declared his resolution to perish with honour in the midst of his friends, rather than yield ingloriously to his enemies. In the meantime Orleans still held out; and the Maid of Orleans appeared, who, by inspring her countrymen, and appealing the English, obliged the latter to raise the siege. This extraordinary woman had promised not only to raise the siege of this city, but also to crown Charles at Rheims, which was still in possession of the English. As soon as she had achieved the first part of her prediction, she insisted that the King should march against Rheims. She was obeyed. Charles set out for that city at the head of 12,000 men, and scarcely perceived as he passed along, that he was marching through an enemy's country. Every place opened its gates to him, and Rheims sent him its keys. He was accordingly crowned there King of France with the usual ceremonies. Soon after this, the Maid of Orleans was taken prisoner, and condemned to be burnt for sorcery and magic; but she had already completely recovered the King's affairs; and the Duke of Bedford dying soon after, Henry VI., who was a very weak prince, was obliged to withdraw his forces entirely from France, the English being expelled from all their possessions on the continent except Calais.

Charles now had time to direct his industry and judgment, to remove the numerous and oppressive evils to which France had been so long exposed. He restored the regular course of public justice; introduced order into the finances; established discipline among his troops; repressed faction in his court; revived the languid state of agriculture and the arts; and in the course of a few years, rendered the kingdom flourishing within itself, and formible to its neighbours. In the midst of his prosperity and wise administration, Charles was extremely troubled by the conduct of the Dauphin. This young prince was possessed of spirit and courage; but his good qualities were tarnished by the roughness of his manners, and the savageness of his disposition. Discontented at court, he retired into his province of
Dauphin; but understanding that his father would not permit him to return to Paris, he took refuge with Philip the Bold, Duke of Burgundy, who willingly gave him an asylum, but would by no means encourage him in the seditious projects which he entertained against his father. When the latter heard of the place where his son had taken refuge, he observed, "The Duke of Burgundy is nourishing a fox, that will eat out his entrails." But in fact, the Dauphin was the cause of the death of the king; for the latter being apprehensive that he would poison him, refused for several days to taste any food, and being thus overcome with hunger and chagrin, he died in 1461. The Dauphin, under the name of Louis XI., succeeded his father. His first and leading object was to aggrandize the monarchy, by depressing the power of the nobles; but the latter took the alarm, and armed to defend their privileges. The King also armed. The battle of Montleroi was fought 1465, which decided nothing; but a peace was concluded on terms advantageous to the nobles. These terms, however, Louis never meant to fulfil; for having gained over many of his opponents, he used his influence with the Assembly of the States, to declare those articles of the treaty void which were most disadvantageous to him. Scarcely, however, had he succeeded in reducing his nobles to subjection by these dishonourable means, when he was again involved in trouble by his own incapacity, and became the dupe of his own artifice. For on the death of Philip the Good, Duke of Burgundy, Charles the Bold, who succeeded him, made preparations against Louis. To these he was prompt, from a thoroughknowledge of his character, with a strong suspicion that Louis would soon attack him. Louis also armed; but as he was always averse to war, he agreed to pay the Duke a large sum of money, and he appointed a personal interview at a place in Picardy, then in the possession of the Duke. Louis went to the place with only a few attendants, in the hope that Charles would come with as few; but at the same time, his emissaries persuaded the inhabitants of Liege to revolt against the Duke. The latter was at first pleased with the apparent confidence of Louis in coming with so few attendants; but intelligence arriving, during the conference, that a rebellion had broken out in Liege, and that it had been instigated by the emissaries of Louis, Charles ordered the King into confinement. In this state Louis remained three days, when he was released by the Duke, on condition, that he should march along with him, and assist him in bringing the inhabitants of Liege back to their duty. Liege was reduced, and Louis was permitted to depart for his own dominions. During the remainder of his reign, this monarch continued to act with his habitual duplicity. He first excited his people to revolt, and then having crushed them, divided with his ministers, who were equally infamous with himself, their possessions. At last even his ministers conspired against him; but being defeated in their schemes, they suffered those punishments which they had so often inflicted on others. His brother Charles was poisoned; the Constable St Paul, his brother-in-law the Count of Armagnac, and the Dukes of Alencon and Nemours, were beheaded; and the children of the last named nobleman were sprinkled with the warm blood of their father, and sent in that condition to the Bastille. With England he formed an ignominious truce for seven years, engaging to pay annually 50,000 crowns of gold; and subsequently, he concluded a treaty at London with Edward IV. by which he stipulated, that the truce should be kept for 100 years after the death of each of the parties, under the original conditions. On the death of the Duke of Burgundy in 1477, Louis proposed a marriage between his son Charles, then only seven years old, and the heiress to the large possessions of that duchy, comprehending not only Burgundy, but Franche Comte, Artois, Flanders, and nearly all the rest of the Netherlands; but he was overreached by his rapacity, for having, even after he proposed marriage, seized on Burgundy as a male fee, the Princess Mary of Burgundy was alarmed, and, by the advice of her Flemish subjects, she married the Archduke Maximilian, son of the Emperor Frederic III. Hence arose those wars, which so long desolated the Low Countries, and created an implacable hatred between the houses of France and Austria.

Notwithstanding this marriage, Louis retained those places in Burgundy of which he had taken possession; and, by the further acquisition of Anjou, Maine, Provence, Bar, Roussillon, and Boulogne, he greatly augmented the kingdom of France. Soon after he had succeeded in these objects, he was suddenly seized with a fit of apoplexy, and, after enduring dreadful torments both of body and mind, died A.D. 1483. The character of Louis XI. is not easily understood: he was undoubtedly a man of considerable talents, which would have been more useful to him, had he not, in so many instances, trusted rather to his artifice than to them. He was absolute, yet not dignified; popular with the great mass of his subjects, by humbling the great; but not generous. The system on which he acted was unjust; yet, where his own views were not to be served, he was so zealous for the administration of justice, that such a character, so composed of contradictions, must always be extraordinary; but, considering the age in which he lived, it is not surprising that he violated every moral principle, and yet resigned himself to the most ridiculous superstition. Yet to this king, the Pope gave the title of Most Christian.

Among the useful establishments of Louis, France is indebted to him for that of posts: he also paid great attention to commerce and manufactures; and, to encourage the latter, he invited silk manufacturers from Greece and Italy, whom he exempted from all taxes, as well as their wives and children. He issued an ordinance, permitting the clergy, nobility, and all other persons, to carry on commerce, without derogating from their rank or civil privileges. He proposed to make a collection of all the written and unwritten laws, in order to compose a regular code, and to abridge the forms of process. He also attempted to introduce uniformity of weights and measures throughout the kingdom; but, on the other hand, he increased the taxes, saying that he levied contributions on the purses of his nobles, in order to spare their blood. On his death-bed, however, he advised his son to lighten the taxes. In short, his predominant character was duplicity and dissimulation; and he frequently said, "If my hat knew my secret, I would burn it." His education of his son, from whatever motives adopted, was by no means qualified to render him fit for a throne; for he was brought up in retirement, seen by nobody but the king's servants, and permitted to engage only in the most childish amusements. He was not even instructed in letters; the king saying, that the only maxim in the Latin language worth knowing, was this: quis non sit dissimulare, nescit regnare.

Had not Charles VIII. his son, been naturally of VIII. good talents, as well as a good disposition, he must have A.D. 1483.
FRANCE.

been ruined by such a mode of education. He was only 13 years old when his father died; and the Duke of Orleans, as first prince of the blood, claimed the regency; but he found a competitor in the Duke of Bourbon, who maintained, that as the Duke of Orleans was only 24 years old, he himself stood in need of a guardian. The states-general were assembled at Tours, and declared that there was no necessity for a regency; they at the same time confirmed the last will of Louis, by which the care of the person of the king was entrusted to his sister Anne of France, lady of Beaujol. This princess being a woman of talents and prudence, and, what was of more consequence, determined to discharge the duties of her situation, made choice of a council for the government of the kingdom, and gave the constable's sword to the Duke of Bourbon, brother of her husband. The speech of the deputy of the noblesse of Burgundy, at the meeting of the states, in 1484, deserves notice: “If,” said he, “any dispute should arise, either with respect to the succession to the throne, or with respect to the regency, who ought to decide it but the people, from whom all sovereigns derive their authority, and in whom actually resides the sovereign power. When I say the people, I mean all the citizens, comprehending the princes of the blood themselves, as the chiefs of the order of the nobility.” The common, or third estate, made a very strong and touching representation respecting the poverty of the kingdom, and they complained of the multiplication of judicial offices, many of which were publicly sold: they demanded that the tribunals should select three men of merit, of whom the king should choose one, to fill any vacant office; that all arbitrary and unequal taxes and impositions should be abolished; and that henceforward, in conformity to the natural freedom of France, no taxes should be imposed without the free consent of the states-general. These representations had not their full effect; nevertheless, the taxes were considerably diminished.

The Duke of Orleans, disappointed in his expectations of the regency, went into Brittany, where he persuaded the Duke of that province to commence an insurrection; but the war was of short duration. The king was everywhere successful; and the victory which his troops gained at Saint Aubin, completed the destruction of the rebels. The Duke of Orleans was made prisoner, and shut up in the Tower of Bourges. It is supposed that his captivity was prolonged, and rendered more irksome than it otherwise would have been, in consequence of the resentment of Anne of France, whose passion he had slighted. As soon, however, as Charles took the sovereignty into his own power, he set him at liberty; and the Duke's gratitude and good sense induced him to become a loyal subject: he even used his influence with Anne of Bretagne, though he was enamoured of her, to induce her to marry the king. This happy union took place in 1491, and put an end to all the civil wars which that duchy had occasioned.

But Charles was not destitute of ambition: Louis XI. as heir of the house of Anjou, had acquired a claim on the kingdom of Naples; he was, however, too prudent, as well as too little inclined to war, to enforce his claim. Charles, on the contrary, as soon as his kingdom was secured in tranquillity, resolved to attempt the conquest of Naples; and he accordingly set out on this hazardous expedition in 1494, almost without money, and with very few troops. At first, every thing promised success; the Italians were not warlike; Florence opened its gates; Charles made his entry into Rome as a conqueror; and the Pope was compelled to grant him the investiture of the kingdom of Naples. He lost no time, but immediately left Rome for his new kingdom. Ferdinand, his competitor, fled at his approach; the city of Naples instantly declared for him; and, while in his whole kingdom, only three towns continued in the interest of Ferdinand. Had Charles not been dazzled by the rapidity and splendour of his success, he would instantly have secured his conquests; but he wasted his time at Naples in festivals and triumphs, and was indulging in the vain and presumptuous hope of being able even to extend his victorious arms to Constantinople, and to subvert the Ottoman empire; while a combination was forming against him of almost all the Italian states, supported by the Emperor Maximilian, and Ferdinando King of Arragon. Charles, therefore, was soon too fatally convinced, that, instead of extending his conquests, or even retaining the kingdom he had acquired, it would be absolutely necessary for him to secure his retreat into France. On every side, his enemies collected in great force; while, to add to the difficulties and embarrassments of his situation, the Duke of Orleans neglected the cause of his sovereign and his country, to engage in an attempt against Ludovico Sforza. Charles's vigour of mind was of great avail in this emergency: At the head of not more than 5000 men, he traversed the Alps, while the confederates, though they had 30,000, were afraid to encounter him in the mountains, and patiently waited for him in an open plain near Placentia. Here the battle of Fornova was fought. Charles was among the first who charged the enemy; and his officers and soldiers, animated by the example of their sovereign, fought nobly and successfully. The Italians fled; but Charles, on account of the very great inferiority of his forces, either was not able or did not deem it prudent to pursue them, but continued his march un molested, and soon afterwards relieved the Duke of Orleans, who was blocked up in the city of Novara by Sforza. Notwithstanding his success, the King of France would probably have found it very difficult to have extricated himself, had not a reinforcement of 16,000 Swiss troops joined him, by means of which he was placed in a situation to dictate the terms of peace with Sforza. In the mean time, Ferdinand returned to Naples, which, however, he did not reconquer, till after an obstinate defence by the Duke of Montpensier, to whom the government of it had been entrusted by Charles.

In 1496, the King of France again prepared to invade Italy, not for the purpose of renewing his attempt on Naples, but in order to support the pretensions of the house of Orleans to the duchy of Milan. But the Duke of Orleans, who was heir to the crown of France, refused to take upon himself the command of the army destined for this purpose. This refusal probably originated not so much from his apprehension of the danger and difficulty of the enterprise, as from his belief that Charles, worn out by debauchery, could not possibly long survive. In consequence of his refusal, and of some other circumstances, particularly his apparent satisfaction at the death of the dauphin, which opened up to him the immediate and almost certain prospect of the throne, he was disgraced, and retired from court to the castle of Blois. The king being thus disappointed in his hopes respecting Italy, and being too sensible that his health was rapidly declining, turned his thoughts entirely to the internal economy of his
Louis XII.
A.D. 1498.

The French again invaded Italy.

In Charles VIII. ended the direct line of the house of Valois; the crown on his death descended to Louis Duke of Orleans, grandson to the first Duke of Orleans. He was 36 years of age when he became king; his disposition and temper were excellent; and he was by no means destitute either of prudence or experience. He soon discovered that he was resolved to forgive the indignities he might have suffered before he came to the throne, remarking, with true magnanimity, that it was not for the king of France to revenge the quarrels of the Duke of Orleans. Louis the XII. (for so he was called) married a daughter of Louis XI.; a princess deformed in her person, and incapable of bearing children, but of excellent qualities. As, however, it was on many accounts desirable that he should have an heir to the throne, he procured a divorce from the Pope, and married Anne of Bretagne, widow of his predecessor. Soon after this marriage, he turned his thoughts to the claims which his family had to the duchy of Milan. Sforza, anticipating Louis' intentions, had made every preparation to defend his dukedom. He repaired all the fortifications, augmented his garrisons, and replenished his magazines; but he wanted the support and good opinions of his own subjects; and he had too much reason to apprehend, that whenever Louis should appear in Italy, they would desert him. The republic of Venice also, to whom some part of the Milanese territory lay very convenient, were tempted to unite with Louis in the hope, or on the condition, of sharing in his conquests. Maximilian, who before had opposed the French in their invasion of Italy, was now on good terms with Louis; so that Sforza had every cause for despondency. Louis himself was persuaded not to lead his army in person; but to give the command to Louis of Luxembourg, Robert Stuart, Lord D'Aubigny, and John Trotman, native of England.

The French army amounted to 50,000 excellent troops; with these, the assistance of the Venetians, and the disaffection of the Milanese to Sforza, success beyond expectation was accomplished. Even the castle of Milan was given up. As soon as the king of France was informed of these successes, he hastened to cross the Alps, and entered the capital of his newly acquired territories. He continued three months in Milan, during which period he gave great satisfaction, by recalling those who had been banished by Sforza, remitting a fourth of the imposts, and establishing a court of justice. But, either from the natural fickleness of the Italians, from their dislike of the dominion of a foreigner, and that foreigner a Frenchman, or from some other cause, scarcely had Louis reached France, when Sforza, who had retired to Inspruck, returned, and found the gates of the principal cities of the Milanese opened at his approach. Even Milan itself received him. But his success was of short duration: He had in his pay a body of Swiss troops: these conspired against him, and delivered him up to the French, by whom he was sent to Lyons, where Louis then resided. The humanity of the king of France pleaded powerfully for Sforza, notwithstanding his repeated treachery and enormities, so that he was not put to death, but only confined in the castle of Loches, where every thing that he could wish for was granted him. Here he died after a captivity of ten years.

The success of Louis with respect to Milan, induced him to extend his views to Naples; but this kingdom he could not expect to conquer without assistance; he therefore agreed to divide it with Ferdinand of Aragon: the city of Naples and the northern half were to be the portion of Louis. He also entered into a treaty with Pope Alexander VI.; but the simplicity and honour of the French monarch were no match either for Ferdinand or Alexander. The confederates indeed were successful. The King of Naples fled from his own territories; and distrusting Ferdinand, who had betrayed him, after having actually concluded a treaty of alliance with him, he threw himself on the liberalism of Louis, who assigned him an asylum in Anjou, with a pension of 30,000 crowns. But scarcely was the conquest of Naples achieved, when Louis and Ferdinand turned their arms against each other: the Spaniards began the quarrel, but the French were slow in revenging the insult offered them, and Louis in a short time was so successful against his new enemies, that he might have added Ferdinand's portion of Naples to his own, had he not been persuaded to a reconcilement of their differences. In 1503, Philip, son of the Emperor Maximilian, who had married the daughter of Ferdinand, passing through France, had an interview with Louis, at which he concluded a treaty with him in the name of the King of Spain, who had granted him full powers for that purpose. By this treaty, among other conditions, the two monarchs were bound to a cessation of arms, and the provinces of Naples originally ceded, were to be guaranteed to each. As soon as the treaty was concluded, it was announced to the commanders of the French and Spanish troops in Italy. The French commander immediately offered to retire with his troops, but Goncalvo, who command ed the Spaniards, under the pretext that Philip had acted without powers from Ferdinand, stated his determination to wait for further instructions. In the mean time he was reinforced by 10,000 German soldiers by Maximilian, and receiving information that Louis was likely to be deserted by his allies, the Pope and the Venetians, and that 4000 French troops which had been intended for their army in Naples were disbanded, under the idea of peace, he was influenced by these circumstances to attack the French general. The result of the battle of Cerignoles was the utter defeat of the French, the death of their commander, and the acquisition of the whole of Naples, with the exception of a few places. As soon as Philip was informed of this treacherous behaviour, considering his own character and honour as deeply concerned, he returned instantly to France, and placed himself in the power of the French monarch. He also restoronly strongly with Ferdinand; his remonstrances, however, were of no effect. Ferdinand preferred power to reputation; but in order
still to deceive Louis, he publicly offered to restore Naples to its rightful sovereign, while at the same time he sent orders to use every endeavour to expel the French. These orders were obeyed, and were successful. Louis at first took this treacherous conduct of Ferdinand very coolly; but soon afterwards he changed his feelings and his determination. He assembled three large armies, for the purpose of invading Arragon on every side, while, at the same time, a considerable fleet was fitted out, to insult the coasts of Catalonia and Valencia, and to intercept the communication between Spain and Naples. But a variety of unforeseen and untoward circumstances disappointed the hopes and the projects of Louis, while he himself was attacked by a fever that threatened his life. As soon as he recovered, A.D. 1509, he diligently applied himself to terminate a war, which had proved so unfortunate; and a treaty was at length concluded, according to which, the Neapolitan nobility, who had been the adherents of Louis, and on that account had been imprisoned by the Spanish commander, were to be released.

Soon after this treaty, the states-general were assembled at Tours. One of their first acts was to bestow on Louis the title of Father of his people. Their next was to repair a fault that their sovereign had committed. He had promised his eldest daughter in marriage to Charles of Austria, afterwards so well known under the name of Charles V. and along with her part of the French territories. To this promise, the assembly objected most strongly, urging that the king had no right to give away any portion of the French territory. Influenced by their reasons or remonstrances, he recalled his promise, and his daughter espoused Francis, Count of Angouleme, heir apparent of the throne.

In 1507, the city of Genoa, which was then dependent on Milan, revolted from the French. Louis resolved immediately to crush the insurgents; and for this purpose, he assembled a numerous and formidable army, forced the passes which the Genoese had occupied, and stormed their entrenchments. He then entered Genoa in triumph. But in the midst of his success, his natural mildness of temper was conspicuous, for he put to death only two of the insurgents, and levied a fine upon the city.

At this period, no monarchy in Europe was more proud than the republic of Venice; while their wealth, acquired by commerce, excited the envy and jealousy of all their neighbours. Pope Julius II. in particular, regarded this state with peculiar eminence; and influenced by this motive, he laid the foundation of the famous league of Cambrai. This league was composed of the Pope, the Emperor, the King of France, and the King of Spain. Louis was induced to join in it, from the belief that the Venetians had contributed to his loss of the kingdom of Naples; but true policy should have kept under such a motive for going to war with the Venetians, as they were the only state beyond the Alps, on whose alliance he could depend. The Pope contented himself with issuing his anathemas against Venice; and afterwards repeating of the alliance which he had formed, he offered to make peace with the Venetians, if they would give up to him two places, that formerly belonged to the church. This condition the republic decidedly refused. Louis seemed most in earnest of all the confederates; he assembled a large army, and put himself at the head of it. He even crossed the Alps; those barriers which had seldom been passed without calamity, by the sovereigns of France. The valour of his troops, animated by the example of their monarch, triumphed over every obstacle. In the battle of Ghiaador, the Venetians were defeated with the loss of 8,000 men. The Pope now was active for his own benefit; immediately seizing all the towns which the republic possessed in the ecclesiastical territories. Ferdinand, on his part, renounced Calabria to his Neapolitan dominions. At the same time, the city of Venice itself was threatened by the armies of Maximilian and Louis; and the absolute ruin of the republic seemed near at hand, when the confederates began to quarrel with each other. The senate of Venice lost no time in profiting by this circumstance, and by well-termed concessions to Ferdinand and the Pope, dissolved the confederacy.

Julius II. now projected a more arduous and extensive undertaking than the humiliation or conquest of the republic of Venice, he hoped, by his efforts, to expel every foreign power from Italy; and his first efforts were directed against the French, against whom he declared war, invading the duchy of Ferrara, and laying siege to Mirandola. At first the King of France was disposed to behold with contempt these efforts of the Pope. Perhaps he was retracted by religious feelings towards the head of the church; but at length, A.D. 1511, he ordered his troops to repel the invasion of Julius, and even to penetrate into the Roman territories. Julius was soon under the necessity of retracting his steps, when the French general was suddenly seized with a mortal distemper, which gave Julius a temporary respite and advantage; but another commander having been appointed, he was again pressed so closely, that he was under well-grounded apprehensions, that it was the intention of Louis to depose him from his holy dignity. To this extremity the French monarch might probably have pushed him, had not his queen interceded and saved his Holiness.

Julius, in return for this clemency, displayed only increased bitterness and enmity against France, which he hoped to render efficient, by forming a new confederacy, called the Holy League. The principal parties of this confederacy against France, were Ferdinand, the Swiss, and the Venetians. At first their armies were successful; but the valour and skill of Gaston de Foix, a name celebrated among heroes, retrieved the affairs of France. This general, after relieving Bologna, and Brescia, and defeating the Venetians with a very inferior force, laid siege to Ravenna with the professed object of compelling or inducing the army of the confederates to give him battle. The two armies were nearly equal in numbers, being about 20,000 each. The battle was long and obstinate. The French were victorious, but their victory cost them the life of Gaston. The day was already gained, when he received information that a body of 4,000 Spaniards still maintained their ground: anxious to render his victory complete, he rushed forward to the charge, with about 20 gentlemen; his horse was killed under him, and he himself, after having fought with the greatest courage, fell, pierced with wounds. The death of this hero was a fatal blow to the French, for they soon afterwards lost all the places which they possessed in Italy; their generals did not agree with each other; the king was without money; the confederates were much superior; and there was no alternative left, but to evacuate the country.

Louis now, A.D. 1513, was threatened with a confe-
deracy similar to that which had so lately humbled Venice. The Pope, Leo X., was to enter Dauphine; the emperor, Champagne; the Swiss, Burgundy; the King of England, Picardy; and the King of Spain, Guienne and Languedoc. But the elements of this confederacy were too discordant long to hang together; the Pope was not fond of war; the emperor accepted subsidies, but neglected to supply an army; and Ferdinand looked to his more immediate interest, as well as to an easier enterprise, in seizing on the kingdom of Navarre. All the confederates, therefore, Henry, King of England, was the only formidable one that remained; and he was eager after glory: this he obtained at the battle of Spurs. But the Swiss, who had entered Dauphine, having retreated, and the rest of the allies, as we have mentioned, having deserted the cause, the King of England, on the approach of winter, re-embarked for his own country.

Anne of Bretagne died the following year, 1514, and Louis, in the hope of having an heir, and in order to destroy effectually the confederacy against him, married the sister of the King of England. Louis was much older than his wife; this he forgot; and in three months after his nuptials, he was seized with a violent disorder, which carried him off. In him expired the older branch of the house of Orleans, and the crown of France passed to that of Angoulême.

The taxes, which had been lessened by Charles VIII., were still further diminished by Louis, while, at the same time, by a judicious mode of levying and collecting them, he rendered those who were constables less irksome and unpopular. Even in the midst of his Italian wars, he laid on no new burdens. It is true, he extended and systematized the practice of disposing of offices for money, but he carefully excepted the judicial functions from this danger and disgrace; they were always filled by men distinguished for their intelligence and virtue. The parliament of Paris not being adequate to the discharge of its duties, since it had been made sedentary, Philip the Fair and his successors had instituted several other parliaments.

Louis XII. still further increased their number, and he issued an edict, by which he gave them authority to recall him to the fundamental laws of the state, if ever he discovered a disposition to evade or abrogate them—a proof of this his wish to govern according to law, but no surety of the object which he had in view. It is said that he always kept two lists, one of the places and favours which he had to bestow, the other of the persons in each province most fit to fill or enjoy them; and on such alone they were conferred. This monarch made a wise, just, and humane distinction between those who offended him in his private character, and those who offended him as the sovereign of France: the last he punished, because he was of opinion that he thus best secured the safety and prosperity of the state; the former he suffered to pass unpunished. Perhaps in no part of his conduct did he display more good sense, or better consult the welfare of his subjects, than in the choice of his ministers; and in the case of the Cardinal Amboise, he even seems to have had the merit, or the talent, of making the same man, under him, the instrument of happiness, who, under another, would probably have been the instrument of oppression and misery.

As soon as it was ascertained that the widow of Louis XII. was not pregnant, Francis, Count of Angoulême, and Duke of Valois, took the title of king. He was at this time 21 years of age, full of spirit and confidence, fond of war and glory, and disposed, as well as enabled, from the circumstances in which he was placed, to give way to that propensity. Before he ascended the throne, he married Claude, the daughter of the late montreux, by Anne of Bretagne. Mary the widow of Louis bestowed her hand on Charles Brandon, Duke of Suffolk.

The first and darling object of the new sovereign, was the recovery of the Milanese; and he resolved to profit by the preparations which had been made by his predecessor; but as money was still wanting, Francis, by the advice of his chancellor Duprat, not only restored the taxes which Louis had abolished, but exposed the offices of the crown to sale, and endeavoured to augment his treasures, by means, if possible, still more unjust, impolitic, and arbitrary. As soon as he deemed himself quite prepared for the conquest, he openly avowed his determination to march against Milan. As his designs had been suspected, a confederacy had been formed against him, consisting of Maximilian, Ferdinand of Aragon, Leo X., Sforza, and the Swiss. But the character of Francis was of such a cast, that the knowledge of this confederacy, instead of leading him to drop or suspend his designs, only prompted him to their more speedy and resolute execution. As the Swiss guarded the Alps, it was necessary either to force the passes of the mountains, or to elude the vigilance of their protectors. Francis chose the latter. His soldiers, into whom he had inspired his own zeal and ardour, cut new roads; and his forces were in Italy, before his opponents thought that he had disentangled himself from the Alps. The first enemy which the forces of Francis encountered, were the papal troops, which were negligently, and securely, as they thought, encamped on the banks of the Po. On these the French poured down, so unexpectedly and with so much violence, that they were speedily and easily discomfited. Hitherto Francis had remained in his own kingdom; but as soon as he learnt of this success, he hastened to put himself at the head of his armies, leaving his mother, Louise of Savoy, regent during his absence.

As soon as Francis assumed the command, he entered the Milanese, and pressed forward to its capital. For its protection and defence, only the Swiss troops were prepared; they were encamped about a league from the city, at a place called Marignano. Francis knew that they were brave; but he also suspected that they might be allured to withdraw from their post. His suspicions were not unfounded. An offer of 700,000 crowns made a strong impression on them, and they were preparing to yield Milan up to the French king, when they were joined by 10,000 of their own countrymen. These troops were not disposed to desert the cause in which they were embarked, and Francis found, that if Milan were to be his, the Swiss must be fought and conquered.

The Swiss, probably ashamed of having listened to the offers of Francis, and resolved to wipe off their disgrace, fought with more than their usual bravery and perseverance. The battle began about four in the afternoon, in the month of September 1515, and three hours after dark, the combatants, fatigued with their exertions, separated, but only to renew the contest, if possible, with more valour and animosity next morning. For some time the issue was dubious, for the Swiss, though inferior to the French, fought only on that account more obstinately: at last they were obliged to give way; 10,000 of them perished on the field of battle; the rest fled, but in their flight they remembered their character, and no
disorder or confusion was visible. The French army also suffered severely, 6000 of their troops having been killed and wounded. On this occasion Francis displayed the valour of a brave man; Charles of Bourbon, his constable, the wisdom and experience of a great commander: to him the success of the battle of Marignano is justly ascribed.

The Swiss were now tired of a contest, in the issue of which they had no immediate concern; and their army was recalled. Sforza, therefore, was left to defend his territories by his own forces alone. His cause was hopeless; but he sought to prolong his fate, by retiring into the castle of Milan. The French army, however, full of ardour, flushed with victory, and guided by the coolness and skill of the Constable, soon compelled Sforza to surrender the castle, on the condition that he should enjoy a retreat and a pension in France.

It was always the policy of the Popes to be among the first to set on foot confederacies to protect Italy from the French, and among the first to desert them. Leo X. acted in conformity with this policy. He sought an interview with Francis, whom he received with a flattery which he knew would find its way to the feelings of the French monarch. After this interview, Francis returned to Lyons.

Had not Francis been more ardent than penetrating, he would not have forsaken Italy at this moment; but he uniformly displayed, through his whole life, qualities and feelings which prompted him to enterprise, but forbade the ultimate and permanent success of his plans. Among the confederates against him was Ferdinand of Arragon. Soon after the return of Francis to his own kingdom, this monarch died. He had always opposed the designs of the French against Naples; his death, therefore, seemed to have removed a serious obstacle to those designs, which, it is probable, were still cherished by Francis. At any rate, a rival was removed, whose experience, subtle arts, and numerous resources, Francis had just reason to dread. Francis, however, did not profit by the death of Ferdinand, though his successor was only 16 years old; and by this want of foresight— for history compels us to ascribe his conduct to any other motive but a scrupulous regard to justice—not that Francis was more lax in this respect than the other sovereigns of his age,—he suffered a rival to rise up in the fulness of his strength, still more formidable than the one from whom death had just freed him. The successor of Ferdinand was Charles V.; and under him were now united a most formidable kingdom in the Old World, and territories in the New, which promised an inexhaustible source of riches.

In the mean time, the Emperor Maximilian had invaded the Milanese with an army of 40,000 men; but the Constable Bourbon, with an inferior force, obliged him to retire. Francis also made an attempt to rescue Navarre from Spain, and to reinstate on its throne its legitimate monarch; but in this attempt he was defeated, principally by the sagacity and prudence of Cardinal Ximenes, who at that time ruled Spain.

Charles V., at his accession to the throne of Ferdinand, was disposed to continue the war with Francis, especially on the side of Flanders, where he was when Ferdinand died; but the Flemings were averse to a war, which exposed them to the loss of their commerce. Francis, on his side, was desirous of securing his conquests in Italy. Under these circumstances, a treaty of peace was easily and speedily concluded at Noyon between the two monarchs. By this treaty, Francis was to give in marriage to Charles his eldest daughter, and with her resign all his pretensions to the throne of Naples. Charles, till the marriage took place, was to pay 100,000 crowns a year to the King of France, in consideration of his being already in possession of Naples; and Francis was left at liberty to support the heirs of the King of Navarre, provided they could not make out their claim to the satisfaction of Charles. Peace was thus restored for a short time; but in 1519, the Emperor Maximilian expired; and it was easy to foresee, that the election of a successor would give rise to hostilities. The probability of this event was still further increased, when it was known that Charles and Francis were competitors for the imperial dignity. They had indeed, from the first, agreed to carry on the competition with emulation, but without enmity; and Francis, with his natural and characteristic vivacity and frankness, declared to Charles, "We are both suitors to the same mistress; the more fortunate will win her, but the other must remain contented." It was, however, not to be expected that the loser would be contented. The prize was of infinitely too great value to be sought for and lost with quiet feelings. As the sovereignty at which they aimed could be obtained only by means of the electors, money and influence, not arms, were to decide to whom it was to fall. Francis was profuse in his expenditure of money on this occasion, but his influence was small. The Germans were partial to the house of Austria; and the voice of Frederick of Saxony decided the contest. Charles was raised to the imperial dignity, and Francis retired disappointed, and ranking after revenge. Influenced by these feelings, he sought and obtained the alliance of Henry of England; but Henry was too fickle a character to be long faithful to his promises. Charles knew this, and a very short time saw the emperor and Henry united. Francis next turned his thoughts towards the Pope, who, hoping to serve his own interest, by employing one monarch to expel the other from Italy, gave encouragement to the expectations and wishes of Francis. By the German constitution, the kings of Naples were for ever excluded from the imperial dignity. According to this regulation, Charles ought not to have been elected emperor; but as his election had taken place, Leo and Francis declared that he had forfeited his right to Naples. This was one cause for war; and another was not wanting. The emperor, as king of Spain, refused to do justice to the heirs of the king of Navarre; and in this event, by the treaty of Noyon, Francis was at liberty to support them. The kingdom of Navarre received the French with open arms. Charles was taken unprepared; his forces were employed in quelling some commotions which had arisen in Spain; and Navarre seemed on the point of being completely conquered, when it was saved to Charles by the rashness of the French general, who, before he had completed the conquest, entered Catalonia, whence he was driven with disgrace, and his army afterwards defeated, and himself taken prisoner. As this war had been carried on by Francis in the name of Henry D'Albret, who claimed the kingdom of Navarre, it did not immediately occasion hostilities between Francis and Charles. In the mean time, the former was nearly deprived of his life by an accident. While he was engaged in the diversion of attacking with snow-balls the house of the Count de Pol, he was wounded in the head by a torch. For a long
time he was seriously ill; and, during the cure of his wound, it was deemed necessary to cut off his hair, which he never would permit to grow again, but introduced the fashion of wearing it short.

As soon as he was sufficiently recovered, he prepared for hostilities; and, taking the field with a numerous army, spread terror through the Low Countries. Charles, on his part, was not slow in meeting his antagonist; and near Valenciennes, the two monarchs, at the head of their respective forces, were opposed to each other. A thick fog at this time prevailed, and the Constable Bourbon entertained his sovereign to take advantage of it, and commence the attack. Francis, however, jealous of the military reputation of the Constable, refused to listen to his advice, and even manifested his jealousy, by bestowing the command of the van, to which the Constable, by virtue of his office, had an undoubted right, on Charles D'Alençon, the first prince of the blood. From this period, the Constable's dislike of Francis may naturally be dated.

Nothing of consequence occurred in the Netherlands; but Charles, who trusted as much, or more, to his intrigues as to his army, contrived to engage Henry VIII. and the Pope on his side. By the treaty entered into by them, it was agreed, that the Pope and the Emperor should unite their forces, for the purpose of driving the French from the Milanese, which was to be restored to Francisco Sforza; that Parma and Placentia should be restored to the Pope, whom the Emperor should also assist in conquering Ferrara. Henry, on his part, agreed to invade France on the side of Picardy with 40,000 men, and to bestow on Charles his only daughter, the Princess Mary.

As soon as Francis was apprised of the storm which threatened his Italian dominions, he prepared for their defence; but as his forces were either employed in the Low Countries, or assembling on the frontiers of Spain, he was obliged to hire a body of men from the Swiss. For this purpose, he raised a large sum of money, which, however, his mother intercepted; and, in consequence of the Swiss troops not receiving their pay, they retired from the standard of Francis. At this juncture, Milan was betrayed to the general of the Pope; the other cities of the duchy followed its example; and the castle of Milan, with a few inconsiderable forts, alone remained to Francis. This great success, however, was indirectly the cause of the dissolution of the confederacy; for Leo X. received the news with such transports of joy, as brought on a fever and occasioned his death. He had kept alive the confederacy, which expired with him. But Francis was still unable to reconquer his territories in the Milanese; and in 1522, Francisco Sforza was restored to the whole of his paternal dominions.

The loss of the Milanese was not the only misfortune which assailed Francis at this time. Genoa expelled the French troops, and opened her gates to the army of Charles. Henry of England openly declared war; and his forces, united with the Flemings, invaded Picardy. But the French, inferior in numbers, baffled the designs of the invaders, by adhering to the politic plan of not fighting; so that at last the English and Flemings were compelled to retreat. As soon as Francis saw that his territories were secure on the side of Flanders, he resolved to march himself into the Milanese. Before, however, he could put this plan into execution, he was alarmed by a conspiracy formed against him at home. The jealousy of the king with regard to the Constable Bourbon, has been already noticed. This nobleman, on his part, could not but feel indignant at the treatment to which this jealousy had given rise. His services, especially at the famous battle of Marignano, had never been required; on the contrary, the king, in more than one instance, had purposely slighted him. Perhaps, however, the feelings which this conduct on the part of the king produced, would not have stirred up the Constable to rebellion, had it not been for another circumstance. The mother of Francis, forgetting her age, fell in love with him. She offered him marriage. He refused her. Her love was thus converted into the most deadly hatred and revenge. A law-suit was commenced against him for the estates, which he held in right of his deceased wife. The issue was such as might be expected; justice was set at nought, and the Constable Bourbon found himself deprived of the greatest part of his property. In this state, he began or renewed his intrigues with Henry and Charles, who gladly embraced his alliances, and formed an actual treaty with him, according to which the conquest of France was projected, and if it were effected, Provence and Dauphine were to be assigned to the constable, with the title of King. In furtherance of this plan, the English monarch was to invade Picardy; the emperor was to enter France by the Pyrenees; and Bourbon was to penetrate with an army of Germans into Burgundy, where he expected to be joined by his numerous and powerful adherents. The period for carrying these enterprises into execution was fixed; as soon as Francis had crossed the Alps, the confederates were to put their respective armies into motion.

As soon as Francis was informed of this conspiracy, he attempted to seize Bourbon; but he escaped, and fled into Italy. Not deeming it prudent to leave his kingdom at this juncture, he entrusted the command of the army destined for the invasion of Italy to Admiral Bonivet, who was totally unfit for his station. The general of the Pope, however, being much inferior in force, was compelled to retire. The greatest part of the duchy of Milan submitted to the arms of France; and had Bonivet known how to act, Milan itself must have fallen. But he delayed attacking it till it was too late; the winter set in, and Bonivet was obliged to protect his troops from its inclemency in quarters. In Burgundy and Guienne, the success of Francis was most complete; the Spaniards and Germans were repulsed. Paris, however, was threatened by the English, who, having landed in Picardy, advanced to within 11 leagues of the capital. Their career was, however, soon checked by the Duke of Vendome; and they were driven out of the French territories with disgrace.

At the commencement of the next campaign, the affairs of Francis in Italy wore a very unfavourable aspect. A numerous army of the allies threatened that part of the Milanese which the French had conquered; and Bonivet was quite unable to contend, either with the superior numbers or the superior talents of his opponents. He was accordingly under the necessity of abandoning his entrenched camp, and crossing the river. During this latter movement, he received a wound in his arm, which obliged him to quit the field. The famous Chevalier Bayard was entrusted with the command during the absence of Bonivet. He animated the cavalry by his presence and example, to withstand the whole of the enemy's troops; but in this service he received a
wound, which he immediately perceived to be mortal. Incapable any longer of sitting on horseback, he was placed on the ground, with his face towards the enemy, and his eyes fixed on the guard of his sword, which he held up instead of a cross. In this posture, he addressed his prayers to God, and expired, regretted equally by his countrymen and his foes, as his ancestors for several generations had done, in the field of battle. Just as he was about to draw his last breath, Bourbon arrived where he lay, and expressed his sorrow at his fate—"Crieve not for me (said the hero), I die, as I lived, true to my king; but I pity you, who fight against your king, your country, and your oath!"

In consequence of the retreat of Bonnivet, which was continued into France, the whole of Italy was wrested from his master. The Cardinal Bourbon, eager after revenge for the insults he had suffered, as well as anxious to conquer his promised kingdom, wished to have invaded Provence; but he was restrained by Charles, who advised or commanded him to lay siege to Marseilles. In this siege, forty days were unprofitably consumed. The King of France advanced to its defence, and Bourbon retired into Italy. Francis, again elated by his success, and untaught by all the reverses which his predecessors, as well as himself, had suffered in their attempts against Italy, resolved to enter that country, and endeavour to regain the Milanese. From this attempt he was in vain dissuaded by the most prudent and experienced of his generals, as well as by his mother. He persevered, and success seemed to sanction his design. The city of Milan opened its gates; the army of Bourbon fled; but Francis did not improve his successes. He consumed the precious time in besieging Pavia, when he ought to have pursued and attacked the enemy in the midst of their consternation and flight. He was still further elated by the Pope and the republic of Florence deserting his adversary, and uniting themselves to his cause. It seemed to him as if the period were at length come, at which it was decreed that the French should be universally and permanently successful in Italy. Regarding the Milanese as secure, he dispatched 60,000 men into Naples, while he himself pressed forward the siege of Pavia. This city, though defended with the utmost gallantry, must have fallen, as it was reduced to the last extremity, when an imperial army advanced to its relief.

The battle of Pavia decided the fate of that city and of Francis. Lannoy and Pescara, the generals who advanced to its relief, were reinforced by 12,000 Germans, dispatched by Bourbon. Still Francis would not have been unfortunate, had he either raised the siege, or continued in his intrenchments; but a false shame prevented him from adopting the first measure, and the foolish and rash advice of Bonnivet induced him to leave his advantage, and enter into battle with his adversaries. This was what they wished for, but it was hardly expected. Even after the imperialists had their advantage under circumstances most favourable to themselves, their success was extremely doubtful; and, in all probability, Francis would have witnessed a drawn and indecisive battle, or at least would not have suffered such a severe and fatal loss, had it not been for the treachery of part of his own army. In the midst of the engagement, the Duke of Alençon, with the troops under his immediate command, that formed part of the left wing, went over to the enemy. About the same time, the garrison of Pavia sallied out on the rear of the French; and the cavalry of the latter, unable to withstand the imperial horse, gave way. Under these circumstances, notwithstanding the exhortations, the example, and the exertions of Francis, the rout became general. The king was himself wounded, and thrown from his horse; yet he defended himself bravely, till at length, exhausted by fatigue and his wounds, he was under the necessity of delivering his sword to Lannoy. On the day after the battle, Francis was conducted to a strong castle near Cremona, and committed to the charge of an officer of great vigilance and integrity.

As soon as the regent Louisa was acquainted with the disastrous battle of Pavia, by a letter from her son, containing these words, "Madam, all is lost except our honour," she put forth all her talents, which had hitherto been expended on useless or dangerous objects, towards the safety of the kingdom; and that it was saved in this hour of unparalleled and imminent danger, must be ascribed to her exertions and talents. She immediately assembled the nobles at Lyons; collected the remains of the army, and recruited it so as to render it fit again to take the field; levied new troops; and, above all, endeavoured to conciliate the King of England. Henry had long been jealous, or afraid of Charles; and Wolsey had not forgotten the promises of the papal dignity, with which the emperor had deceived him. But it was evident, that whatever steps the King of England might be induced to take, immediate measures on the part of France itself were indispensably necessary; and when the storm had passed away for a little time, it was discovered that it was not in the power of the Imperialists to profit so much by the victory of Pavia as they had hoped, and France had dreaded. Lannoy found himself under the necessity of disbanding the greatest part of his army for want of money. The character of Charles in a great measure saved France; for, instead of drawing his advantage by the same means by which he had acquired them; instead of augmenting his armies and pushing his conquests into France,—he endeavoured to gain from his royal captive, by intrigue and negotiation, what he probably could have wrested by force. But Francis indignantly rejected the base and dishonourable terms, and displayed, on the occasion, such spirit, that Lannoy thought it more prudent to send him into Spain, for the purpose of a personal interview between him and Charles. But this interview, at first, was productive of no effect. Charles behaved to him with so much duplicity, and evidently endeavoured to extort from him such dishonourable terms, that Francis, in despair, entrusted to his sister, the Duchess of Alençon, a deed, by which he resigned his kingdom to the Dauphin. This circumstance at last induced Charles to behave with more openness and honour towards his captive. He was also threatened with a confederacy against him, which had for its objects to liberate Francis, and to humble and curtail the power of his conqueror. By the treaty of Madrid, Francis regained his liberty, and, as the price of it, restored Burgundy to the emperor in full sovereignty, as well as Artois and Flanders. As hostages for the regular and honourable fulfilment of these conditions, Francis gave his two eldest sons. In order to render the union between him and the emperor more binding and lasting, he was to marry the emperor's sister, the queen-dowager of Portugal, and to cause all the articles to be ratified and registered by the states. Even these terms did not satisfy the emperor; for, suspicious of the integrity of Francis, he bound him by an oath to return as a prisoner into Spain, if, within a limited time, all the stipulations were not fulfilled. It was not indeed probable, that the French sovereign
would himself be willing to execute such stipulations, or, if he were, that his states would permit the kingdom to be so disannointed; and, even while he was yet at Madrid, he assembled the few councillors in whom he could confide, and before them solemnly protested against a treaty which had been extorted from him, and which he therefore deemed null and void. The articles, however, were ratified in France, as, till that ratification arrived at Madrid, Francis was not to be liberty to depart; but, as soon as Francis passed the boundaries between France and Spain, he mounted his horse, waved his hand over his head, and joyfully explained several times, "I am yet a king!"

Scarcely had he reached Paris, before he disavowed the principal article of the treaty of Madrid, that by which he agreed to cede the province of Burgundy to Charles; but, in order to colour and excuse this infraction of the treaty, the deputies of that province waited on the king, in the presence of the ambassadors from Charles, and represented, that no sovereign could alienate their country from the crown, or transfer it to another, without their consent; and that, therefore, as Francis had done that, which he had no right or authority to do, the cession of Burgundy must be looked upon as void. Francis assented to these arguments; but at the same time he offered, in lieu of Burgundy, to pay the emperor two millions of crowns. Charles, as might be expected, rejected the proposal; and resolved to have recourse to arms, for the purpose of compelling his adversary to fulfil the treaty of Madrid.

But while the fate of Francis had excited the pity,—the ambition and power of Charles had roused the jealousy, or the apprehensions of the other European sovereigns. The Pope, the republic of Venice, and the Duke of Milan, entered into the confederacy, of which, under the appellation of the Holy League, Henry King of England was declared the head and the protector. Scarcely, however, was this confederacy formed A.D. 1527, when its dissolution appeared at hand: The Milanese, indeed, had been over-run by the Constable Bourbon; but his soldiers not reaping from the conquest of this exhausted territory all the plunder they had anticipated, he was obliged to march them against Rome. This march, perhaps as much as any of the exploits of the Cardinal, proved the greatness of his military talents: it was executed in the depth of winter, with an army of 25,000 men, destitute of money, magazines, and artillery, and in the face of a superior army; but Rome was reached; and Bourbon was on the point of witnessing the capture of the capital of the ancient world, when a random shot deprived him of life. The command of his troops devolved on the Prince of Orange; they were eager for booty, and for revenge, on account of the death of their general; and Rome became a theatre of carnage and desolation, the Pope himself being made prisoner.

But the splendour of this expedition, and its immediate success, by no means compensated for the injury which it did to the cause of Charles: the Milanese were left exposed; Catholic Europe was indignant and horrified at the conduct of the Pope; the states of Italy were wearied with the yoke of Charles, and an army sent under these circumstances by Francis, was received with congratulation and gratitude. After the French commander had succeeded in reconquering nearly the whole of the Milanese, he directed his march towards Rome, from which place, after having liberated the Pope, he resolved to proceed to Naples. The imperial army was unable to contend with him; all the Neapolitan territory, with the exception of the capital and Gaeta, submitted to the invaders; the fleet of the emperor was defeated; and the French at last seemed to have secured the object, after which they had so long and so frequently directed their efforts. But Francis' character was much better suited for rapid and splendid enterprises, than for such as required continued effort, circumspection, and foresight: Elated with his success, he forgot that his troops still must be supported and paid; he neglected or disgraced his Admiral Doria, to whose skill and valour he had been indebted for his naval victory; he even ordered him to be arrested, because, with a freedom, which the circumstances justified, which his republican birth and education might have excused, and which probably arose in some degree from his attachment to Francis, he opposed some designs of the king, which he deemed injurious to his honour, as well as to the interests of Genoa. Doria, apprised of his danger, escaped the meditated arrest, entered into a negotiation with the emperor, and sailed back to Naples, which he protected and delivered. In the mean time, the discontents of the French army increased; they were in great want of provisions; constantly harassed by their opponents, and at last attacked with a contagious disorder: of this their general died; and his successor found himself under the necessity of evacuating Naples. Doria now triumphing over Francis, was resolved to effect the liberation of his native city; and as the French garrison of Genoa was reduced by desertion to a very inconsiderable number, he had soon the satisfaction of entering it, where he was hailed as the father of his country, and the restorer of its liberty.

The dreams of conquest which Francis had indulged, being thus dispelled by his reverses, he turned his thoughts to peace; which, however, he might have found it difficult to have gained, had not Charles at this time been alarmed at the progress of the Turks, the progress of the Protestant religion in Germany, and the discontents in Spain. In consequence of this mutual disposition for peace, the treaty of Cambray was formed. Charles gave up his pretensions to Burgundy, Francis, on his part, renounced all his right to the Milanese, Flanders, and Artois, and espoused Charles' sister, the widow of the King of Portugal. He also agreed to give two millions of crowns of gold for the ransom of his sons. With this money he was supplied by Henry VIII. of England. These terms were not very honourable or advantageous to France. But the French monarch stained his reputation, by abandoning his allies, the Venetians, the Florentines, and the Duke of Ferrara, to the mercy of Charles.

Francis now had been for nine years, from 1525 to 1534, almost constantly at war. His kingdom was nearly exhausted; and not only did its finances require his care, but its internal regulations in almost every other respect. To these objects, therefore, he devoted some part of his time; but a larger portion of it was given up to luxury, the patronage of letters, and the protection of the fine arts. During this repose from war, the most important events were the annexation of the province of Bretagne, to the crown of France with the consent of the dukes, and the marriage of his second son Henry with the celebrated Catherine of Medici, by which union he hoped again to open a path for the entrance of the French into Italy.

Francis had never regarded the terms of the peace of Cambray, as advantageous or honourable to himself; and consequently had eagerly looked forward.
France.

History.

Francis breaks the treaty.

A.D. 1533.

for a good opportunity or excuse, in order to break them. This opportunity occurred in the year 1535; five years after the treaty was concluded. Charles, at this time, was absent on an expedition to Africa. Sforza had put to death the French agent at Milan. Thus an excuse for hostilities was afforded, as well as a good opportunity for commencing them. The Duke of Savoy, however, refused permission to the French to pass through his dominions; but he could make no effectual resistance. Savoy itself was soon conquered; and Piedmont alone remained to the Duke. Sforza, alarmed at the approach of the French army, is said to have expired with terror; and every thing seemed to promise a rapid fulfilment of the wishes of Francis. Again, however, he was destined to be disappointed. The Pope would not second his enterprise. Henry of England offered to support him, but on the condition that Francis should, like him, throw off the papal supremacy. To this condition, Francis refused his assent. The Protestant princes of Germany, to whom, as the natural opponents of Charles, he next turned his attention, renounced his alliance, because he persecuted their brethren in religion. He then began to feel that, on his own resources and vigour alone he must depend in his war with Charles. But this consideration failed of producing corresponding conduct. Instead of profiting by the unprepared state of Charles, he suffered himself to be duped by his professions. At last he saw his folly. While the emperor was amusing him with the hope that the Milanese should be restored to France, he entered Piedmont with an army of 40,000 infantry, and 10,000 cavalry. This country soon yielded to him; and Francis next saw him direct his attention and his march against the southern provinces of his kingdom. On this occasion, Francis conducted himself with a degree of prudence, which could not have been expected from his sanguine disposition. Instead of marching to the frontier to give his opponent battle, he resolved to act entirely on the defensive; to garrison the strongest towns; and to lay waste the country as the enemy advanced, so as to deprive him of subsistence. This plan was entrusted to Montmorency; and to no other person could it have been entrusted. He acted strictly according to the directions and the design of his sovereign. Charles advanced into Provence, but he found it deserted and desolate. There were no inhabitants, no cattle, no grain. The open towns submitted, but the fortified places resisted. Before one of these, the French general had encamped his army; but in such a situation that he was invincible, and the town was safe, unless the emperor could tempt or provoke him to give battle. This Montmorency cautiously avoided. For two months, Charles besieged the town; but he made not the least progress, while famine and disease thinned his ranks, and dispirited his troops. At last he was compelled to retreat. Now Montmorency came forth, and hung upon the rear of his opponent. Perhaps the emperor and his army might have been totally destroyed; but the French general, even under the most favourable circumstances, would not depart from his plan, and hazard a battle; declaring that a bridge of gold a Frenchman was made for a flying enemy.

About the same time that Charles entered Provence, another of his armies invaded Picardy; but it was equally unsuccessful. Francis now was at the height of his prosperity: His great rival was defeated and disgraced: His dominions were proved to be invulnerable when properly defended. He himself had gained pru-
dence and experience: The rashness and folly of youth had yielded to the cool and comprehensive wisdom of age; but in the midst of these flattering circumstances, a most poignant disaster overtook him,—the dauphin died suddenly, not without suspicion of being poisoned.

In the beginning of 1537 a curious scene was exhibited, which seems to prove, that the natural foibles of Francis' character were too deeply implanted to be entirely extirpated by age and experience. He summoned the emperor to appear before the parliament of Paris, to answer as his vassal for the counties of Artois and Flanders; and on his refusal, declared them forfeited to the crown of France. He even marched into the Low Countries; but either not being sincere, or not able to carry his purpose into effect, a suspension of arms was agreed upon, which was afterwards followed, A.D. 1538, by a truce for ten years. Shortly after this truce was agreed upon, Charles, on his voyage to Barcelona, was driven to take refuge in a small island on the coast of Provence. As soon as Francis heard of this, he proposed a personal interview, to which the emperor consented; and thus these two rivals, after twenty years of hostility, met each other, and vied in expressions of respect and friendship.

In the following year they had another interview. In consequence of the revolt of the people of Ghent, it was necessary for Charles to pass into the Netherlands from Spain. As expedition was necessary, he did not wish to pass through Germany, in which country, he must have travelled with so much ceremony and pomp, as must have delayed his progress. He did not like the uncertainty and risk of a voyage; he therefore resolved to pass through France; and, in order to induce Francis to permit this passage, and not to take advantage of it, by detaining him, he represented to that monarch, that he would cede the Milanese to him. Francis agreed to the proposal, and received and treated Charles with the utmost respect and magnificence, during his six days abode in Paris. A banquet of Triboulet, the fool at the court of Francis, on this occasion, is recorded: He wrote on his tablet, that Charles was a greater fool than himself, thus to expose himself in passing through the territories of his rival. "But what will you say, (observed Francis,) if I let him pass unmolested?" "I shall efface his name, and put yours in its stead," replied the fool.

As soon as the emperor had arrived in Flanders, the ambassadors of Francis required that the Milanese should be restored to their master. At first Charles gave no direct or decisive reply, till at last having reduced the Flemings to submission, he boldly averred that he had never given any promise to restore the Milanese. Francis was completely ashamed at his own folly, in thus being the dupe of the emperor, and at the same time was filled with indignation and the spirit of revenge; but he could not immediately commence a war, for, by his interview with Charles, he had excited the suspicion, or produced the indifference, of the king of England. The pope seemed resolved to maintain his neutrality. The sultan alone listened to his schemes of revenge and warfare. Still, however, Francis could scarcely feel himself justified in the eyes of Europe to commence hostilities, merely because the emperor had given him a loose promise to restore the Milanese, and had not kept that promise; but a more solid reason was not long wanting. Two French am-
The Duke of Orleans reduced the greater part of Luxembourg; the dauphin laid siege to Perpignan: but, on a report that the emperor was advancing to its relief, the duke abandoned his conquests in Luxembourg, and hastened to support the dauphin. Perpignan was defended by the Duke of Alva, who had instructions from his master to hold out to the last extremity, as it did not enter into his plan to raise the siege. The event proved that Charles was wise in his determination; for three months the French endeavored to reduce it, but their troops fell before fatigue and disease; and after that period, they were under the necessity of retiring from before it. The armies of Francis were equally unsuccessful in their other attempts against the dominions of the emperor, so that he saw his vast preparations came to an utter uselessness.

The year 1544 was distinguished by few events of moment. Rochelle had revolted, but it was soon reduced. Luxembourg was occupied by the armies of Francis; and the city of Nice was besieged by that monarch, in conjunction with his ally the sultan: but this alliance was by no means prudent or politic, as it gave great offence to those who might otherwise have united with Francis, that he should have allied himself to an infidel; and this evil consequence of his alliance was not counterbalanced by success, for Nice was not reduced. The year 1544 was distinguished by the battle of Cerizoles. The young Count D'Enghien, had penetrated into Piedmont, where he was opposed by the imperial general the Marquis del Guasto. The armies met at Cerizoles, and the Imperialists were defeated; but the victory of the count was of little avail. The emperor, and Henry of England, (who at length had taken a decided part against Francis,) had entered Picardy with two numerous armies; and, as Francis was by no means equal in force to his opponents in this quarter, the count was obliged to abandon the fruits of his victory in Italy, and hasten to the north of France.

The year 1545 were the affairs of the French monarch, to all appearance, more desperate than at this period. The force of his enemies was so powerful, and his own means of resisting that force, or delaying its progress, so inadequate, that had Charles and Henry united their armies, Paris, in all probability, would have fallen:

But they were not men likely to agree long in opinion; besides being suspicious of each other, they were both obstinate in their dispositions. Charles wasted his time in the siege of St Dizier, while Henry's immediate interest directed him against Boulogne. From these attempts neither of them would desist, even though they might have perceived, that if they gave them up for the present, Paris would be their immediate reward, and St Dizier and Boulogne would not long hold out after the capital was reduced. At this crisis, Francis, who had been long unable, from illness, to head his armies, committed the command of them to the dauphin, who was not insensible to the dangers and difficulties of his situation, but who conducted himself, on this occasion, with considerable skill and prudence. St Dizier was bravely defended; nor would it have fallen if artifice had not been employed. On its reduction, though the emperor's army was considerably weakened by the losses it had sustained during the siege, he resolved to penetrate still farther into France. Champagne was invaded, and Château-Thierry was taken,—a place within two days march of Paris. The fate of the capital seemed inevitable, when the dauphin threw himself between it and the enemy; but he still cautiously avoided a battle, contenting himself with incessant skirmishes, and with depriving the enemy of the resources of the country. This plan had its desired effect: Charles, straitened for forage and necessaries, listened to terms of accommodation, and a definitive treaty was signed at Crespy. By this treaty, Francis resigned his acquisitions in Piedmont and Savoy; and the emperor engaged, in the space of two years, to grant his daughter or his niece in marriage to the Duke of Orleans; and, as a portion, to give up either the Low Countries or the Milanese. It is evident, that this treaty, like the rest which Francis had entered into with his opponent, was favourable to the latter, in so far as the cessions to him were immediate and certain; and of doubtful advantage to the former, in so far as it contained merely a promise of a future cession to him; while, by such arrangements, reasons for future warfare were supplied.

While the negotiations between the Emperor and Francis were going on at Crespy, Boulogne had fallen into the possession of the king of England; and as that treaty contained no stipulation respecting Charles' ally, it was necessary for Francis to recover Boulogne, either by force or negotiation. He chose the former, and sent an army, under the Duke of Orleans, for that purpose. But, at a place between Abbeville and Montreuil, the duke died, and the enterprise was abandoned. The insincerity of Charles in this condition of the treaty of Crespy, was immediately made manifest; for he declared that the death of the Duke had freed him from all his agreements respecting the Low Countries, or the Milanese.

The Count D'Enghien did not long survive the Duke; and the mind of Francis, already weakened by his long and severe illness, sunk before the impression of these calamitous events. Even an advantageous peace with England did not mitigate his grief, and renew his energy; for it was more than counterbalanced by the enmity and intrigues of his own mistress, the Duchess D'Estampes, and of Diam de Pottier, the mistress of the Dauphin, who divided the court into open and implacable factions. The death of Henry of England, which happened in 1547, also preyed on the mind of Francis, as he had long known and personally loved that monarch. In this state of grief and despondency, he wandered about from place to place, in the vain hope of restoring his health of body, or recovering his tranquillity and firmness of mind; at length he died at Rambouillet, in the 33rd year of his age, and 32d of his reign.

The character of Francis was strongly marked. One of the distinguishing features of his mind was promptitude and decision: his quick perception and his great activity, led him to resolve instantly, and to follow up his resolutions by vigorous action; but he did not persevere; difficulties, which at first only prompted him to greater efforts, if they were of long continuance, and especially if they did not promise anything splendid in their overcoming, soon wearied him out. Thus he often abandoned his first designs, and relaxed from his original vigour,—often through impatience, and sometimes...
through mere fickleness. His courage was undoubtedly great; but it was rather courage which could act than support; which rose above the greatest dangers, if they called for activity and exertion, but which cooled, if these dangers were to be shunned or endured rather than overcome. He possessed wonderful quickness and activity of mind, which often enabled him to foresee and defeat the more secret plans of the Emperor; but which, at other times, were rendered comparatively useless in this view, from the thoughtlessness of his disposition and the warm sincerity of his heart. His mode of carrying on war was stamped by the peculiarities of his character. At the commencement of a campaign, his mind was on his enemy with all his force, and he endeavoured to attain his object, by the decision and rapidity of his first movements; but he seldom had any regular and comprehensive plan of warfare, the consequence of which was, that with whatever appearance of ultimate and permanent success he commenced hostilities, he generally found himself, at the end of the campaign, in a much worse condition than he had been at the beginning of it.

It will appear from this sketch, that his faults as a sovereign were of that nature which seldom fail to captivate the multitude, as they all proceeded from a frank disposition and a generous heart. Indeed his subjects seem to have overlooked his failings, and the consequences on their tranquility to which they gave rise, in the splendour of his talents and amiable qualities. It may, perhaps, be with strict justice asserted, that Francis is the first gentleman, in the strict and most honourable sense of the word, of whom we have any record; there was a polish about his manners, an amiability about his manner of acting which was common and his mode of performing them, a delicacy and sense of honour about his whole conduct, which characterised the real gentleman. To the period of his reign, therefore, we may justly trace those features in the character of the higher society in France, for which it was so long and so justly celebrated in Europe. Anne of Bretagne had begun to introduce ladies at court; but it was not till the reign of Francis that they appeared there regularly, or that they were considered as an essential part of it. The consequences were soon experienced; they insensibly gave a softness and a polish to that rudeness of manners, which the comparative ignorance and barbarism of the age, as well as its martial habits, necessarily generated. To the reign of Francis, we may also trace that spirit of intrigue, both political and personal, which long distinguished the French court, equally with the polish of their manners. In short, those who are desirous of detecting the germ of many of the characteristics of the manners of French high life, and of the maxims and practices of the court, such as they existed before the revolution, ought carefully to study the reign of Francis I.

It was during this period, that the religious disputes commenced, which afterwards agitated France so generally, and gave rise to such long and bitter civil wars. Calvin was a native of Noyon in Picardy, and was protected by Margaret of Navarre, sister of Francis; these circumstances had some influence in causing his tenets to take root and spread in France. But those who embraced them soon became the objects of persecution. Francis at one period (as has been already mentioned) was desirous of uniting himself with the Protestant Princes of Germany, against the Emperor Charles; but fearful of awakening the indignation of the Roman pontiff, and the prejudices of his people, by his negotiations with avowed heretics, he seized the first opportunity to prove the soundness of his faith, by ordering six of his subjects, who had embraced the Protestant religion, to be publicly burnt; he himself being present at the execution, and declaring, with his usual and characteristic vehemence, that if one of his hands were infected with heresy he would cut it off with the other, and would not spare even his own children if found guilty of that crime. Even before the time of Calvin, it appears that the French had imbibed the reformed religion; for the inhabitants of Cabrieres and Merindol, small towns in Provence, followed the opinions of the Waldenses; and on this account the Parliament of Provence issued against them a decree, so barbarous and cruel, that the execution of it was suspended by orders from the court. But some years afterwards, in 1545, from what cause is not known, it was carried into execution by the Cardinal de Tournon, a man of a most cruel and bigotted disposition. At this period, part of the French army was returning from Italy; and these were employed against the defenceless inhabitants of Cabrieres and Merindol, 3000 of whom, without distinction of age or sex, are said to have been massacred. Nor was this barbarous work confined to these places; twenty-two other villages or towns were reduced to ashes, in the vain hope of utterly extirpating the heresy.

When Henry II. son of Francis I. mounted the throne, he was 29 years of age. One of the last and most urgent commands or requests of the dying Francis to his son was, that he should never recall the Constable Montmorency, and that he should, by all means in his power, repress the ambition of the family of Guise. Henry, however, was inattentive to the injunctions of his dying father. The Constable Montmorency was recalled and loaded with honours; and the house of Guise were entrusted with his confidence. Henry did not long remain faithful to his wife Catherine of Medici; indeed it would appear, that at this period she either did not possess, or exercise, those qualities and seducing arts for which she afterwards became so famous; since her husband deserted her, and gave himself up, a blind and willing slave, to Diana de Poitiers, whom he created Duchess de Valentinoin, though she was 20 years older than himself.

Before Henry had ascended the throne, his Queen had brought him a son, who was named Francis. In 1548, on the death of James V. of Scotland, Mary his daughter, then an infant, succeeded to the throne of that kingdom. Taking advantage of this circumstance, the ministers of England endeavoured, by force of arms, to obtain for Edward VI. the hand of the infant Queen of Scotland. This the ministers of Mary resisted, and the King of France sent a powerful army to the support of his ancient allies. In return for this assistance, the Scotch entrusted their Queen to the French admiral, on his return to France; and soon after her arrival in Paris, she was betrothed to the Dauphin.

In 1549, a dangerous rebellion broke out in the province of Guienne; and, as Montmorency and the Duke of Guise were the most confidential ministers of the King, they were dispatched to quell it. Their conduct on this occasion was diametrically opposite: the constable endeavoured to repress the rebellion by the most violent and cruel measures; while, on the contrary, the Duke of Guise claimed the insurgents by his conciliating address, and lenient measures. To this line of conduct he was probably led, by that ambition which afterwards so decidedly marked the character of his fa
Henry prepares for war with Charles.

To obtain the objects of this ambition, it was necessary that they should become popular; and the Duke, by his measures in Guienne, undoubtedly acquired great popularity. The reformed religion at this time was making certain, though not very rapid progress in some parts of France. The King was naturally of a mild temper, and a humane disposition; but these qualities were not sufficiently strong or enlightened, to withstand the blind and intemperate zeal of the age; and Henry commanded a number of proslavets to the new doctrines to be burnt in his presence.

The following year, Henry, by the advice of his ministers, directed his attention to the recovery of Boulogne from the English. It is not improbable, that if he had gone to war with this object, he might have been successful, as the English councils, during the short reign of Edward VI., were weak and distracted; but this very circumstance induced him to hope, that, by means of negotiation, he should succeed with even more certainty, and with much less expense and trouble. He accordingly opened a negotiation with the ministers of Edward for the restoration of Boulogne; and on his offering 400,000 crowns, they immediately accepted it, and surrendered this important place. A formal peace was soon afterwards concluded between France and England, in which Scotland was included.

It was scarcely to be imagined, that the long and arduous struggles in which Francis I. had been engaged with the Emperor Charles V. should not have made an impression on the mind of Henry, and led him to regard that monarch almost as his hereditary and natural enemy. His personal feeling was strengthened and confirmed by political motives and views. The treaty of Crespy could not be regarded as advantageous or honourable to France. The only provision in it, which in the smallest degree bore this appearance, related to the Duke of Orleans; and even had he survived, and had Charles fulfilled this provision respecting him, the crown of France could only have been indirectly benefited: but there was too much reason to suspect, that Charles never intended to fulfil this part of the treaty, and at any rate, by the death of the Duke of Orleans, he publicly declared, that he was no longer bound by it. Henry, therefore, considering the treaty of Crespy as injurious to his interest, was not sorry that Charles, by refusing on the plea of the Duke of Orleans, to fulfil his part of it, had afforded him a very fair pretext openly to protest against it. This he accordingly did, and immediately afterwards prepared for war. His great object was the reconquest of the possessions which the French formerly held in Italy; and the state of that country filled him with the hope, that he should attain that object. The duchy of Parma had been given to Octavio Farnese, the grandson of Pope Paul III.; and Julius III. on his accession to the apostolical throne, had at first confirmed him in the possession of it. But he withdrew his support, and revoked his grant, as soon as Gonzaga, governor of Milan, a sworn enemy of the house of Farnese, prepared, by permission of the Emperor, to make himself master of Parma. In this critical emergency, Octavio applied to Henry, as the only prince powerful enough to protect him against Charles, and at the same time disposed, both from his antipathy to Charles, and his anxiety to re-establish himself in Italy, to afford him support. Henry having not only settled his own domestic concerns, but brought his transactions with the two British kingdoms to such an issue as he desired, was at complete leisure to pursue the measures, which his hereditary jealousy of the Emperor's power naturally suggested. He accordingly listened to the overtures of Octavio; and, glad of an opportunity of gaining a footing in Italy, furnished him with what assistance he desired. The army which Henry sent into Italy, was commanded by the Marshal Brissac. The imperial troops were under Gonzaga. Still, however, the two monarchs issued no declaration of war, but, on the contrary, affected to maintain inviolably the treaty of Crespy. The war of Parma, as it is called, was distinguished by no memorable event. The army of France ravaged part of the ecclesiastical territories, while the Imperialists penetrated to the gates of Parma; but they were obliged to relinquish the siege of that city with disgrace.

At this period, the council of Trent was summoned to meet; but the alarm occasioned in Italy by the war, prevented most of the Italian prelates from repairing to it on the day appointed, so that the legate and municii found it necessary to adjourn to a future day, hoping that such a number would then assemble, as would enable them to begin their deliberations. While that day elapsed, the French ambassadors demanded audience, and protested, in his master's name, against an assembly, called at such an improper juncture, when a war wantonly kindled by the Pope, made it impossible for the deputies from the Gallican church to resort to Trent in safety, or to deliberate concerning articles of faith and discipline with the requisite tranquillity. He declared, that Henry did not acknowledge this to be a general ecclesiastic council, but must consider and would treat it as a particular and partial convention. The legate, however, affected to despise the protest of the King of France; the prelates proceeded to determine the great points in controversy; and the Emperor, by his authority and confluence, endeavoured to establish the competency and jurisdiction of the assembly. It is unnecessary here to particularize the proceedings of the council of Trent. They were so directly against the Protestants, that Maurice of Saxony, and the other Lutheran princes, who, under the promise of liberty of conscience, and other advantages, had been induced to assist the Emperor against the confederates of Smalkalde, were now made sensible that they had been duped by him, and that by their own force alone, could they expect to preserve the religion which they had embraced, from persecution and probable ruin. But Maurice, who, from his superior talents, as well as his superior power, took the lead among the Lutheran princes, was fully convinced, by his knowledge of the character of the Emperor, that it would be absolutely necessary to proceed with the utmost degree of circumspection and caution, so as to excite no suspicion, till all his measures were taken, and his scheme was completely ready to be carried into full execution. By his former conduct he had lost, in a great measure, the good will and confidence of the Protestants. These it was necessary for him to regain; but while he was regaining them, it was equally desirable and necessary, though still more difficult, to retain the good will and confidence of the Emperor. In the execution of his enterprise he succeeded most thoroughly, conducting an intricate plan of policy in such a manner, as to deceive the most artful, experienced, and suspicious prince in Europe. Having negotiated a new confederacy of the Protestants, of which he was appointed the head, it became necessary to strengthen that confederacy by every means in his power. With this view, Maurice turned his thoughts to the King of France. There could be no doubt that Henry would most cheerfully embrace any plan, the object of which
was to curtail the power and influence of the Emperor, provided his religious opinions did not create an objection. These, therefore, it was necessary to consider in the negotiation. It was also necessary for Maurice to anticipate and obviate any scruples or jealousies, which the Protestant princes of Germany might feel on forming an alliance with a prince, who was not only a Catholic, but who had already persecuted the reformed religion in his dominions. The repugnance and scruples of both parties were overcome, when Maurice was convinced of the policy of Maurice; and a treaty was concluded between Henry and the Protestant confederation.

As soon as the preparations of Maurice were completed, and he had assembled his army amounting to 25,000 men, he published a manifesto, containing his reasons for taking arms; to secure the Protestant religion; to maintain the constitution of Germany; and to deliver the Landgrave of Hesse from his protracted and unjust imprisonment. To this the King of France, in his own name, added a manifesto, in which he assumed the extraordinary appellation of "Protector of the liberties of Germany, and its captive princes."

As the Emperor was totally unconscious of the intentions, and uninformed of the hostile preparations, of the Protestant confederates, and of Henry, he was not in a condition to oppose such formidable enemies. Lorraine was immediately invaded by the French armies. The young Duke Charles, the nephew of the Emperor, was seized. Toul, Verdun, and Metz were occupied. Nor was the enterprise of Maurice in vain, as the young Duke Charles, opposed the conquest of Lorraine by the French; for, while they were thus rapid and successful in this quarter, Maurice marched directly towards Inspruck, where the Emperor was, hoping to surprise him in that open town.

But in this he was disappointed, as Charles, informed of his danger a few hours before the arrival of the enemy, hastily fled; nor did he stop till he arrived at Villach in Carinthia.

Charles now found himself under the necessity of dividing his enemies, in order to save himself from ruin. He accordingly agreed that the king of the Romans should meet Maurice at Passau, where, after considerable delay and difficulty, in the month of July 1552, the memorable treaty of Passau was signed, by which the civil and ecclesiastical independence of the German princes was secured. In this treaty, however, the confederates totally overlooked the services of Henry, and the union they had formed with him. There appears, indeed, to have been some reason for this forgetfulness of their ally; since his measures and operations, though undoubtedly such as weakened Charles, seemed too openly directed to his own aggrandizement, even at the expense of the Germanic empire. For Henry had endeavoured, by artifice, to possess himself of the city of Strasburgh; and had he succeeded in his attempt, the navigation of the Rhine would have fallen into his power. But he was compelled to desist, by the interference of the German princes, and the Swiss cantons.

As Metz, Toul, and Verdun, which Henry had conquered, formed the barrier of the empire on the side of France, Charles was deeply affected by their loss; and as soon as he had concluded the treaty of Passau, he resolved to employ the most vigorous and powerful measures for their recovery. He therefore left his retreat at Villach, and put himself at the head of the forces, which he had assembled against the confederates. This army amounted to 60,000 men. At first, in order to conceal his real object, he circulated a report, that he intended to lead it into Hungary against the Turks; and when the line of his march unequivocally proved that such was not his intention, he pretended that he was marching, in the first place, to chastise Albert of Brandenburgh, who had refused to be included in the treaty of Passau. Henry, however, was not deceived; but guessing at the true object of the emperor's armament, he resolved vigorously to defend his conquests. As it was easy to foresee that the reduction of Metz would be the first object of the emperor, Henry resolved that it should be defended in the best possible manner. He therefore appointed to the command of it Francisco of Lorraine, Duke of Guise. No finer man could possibly have been chosen for this arduous enterprise. He was full of military ardour and zeal; anxious to distinguish himself, and to be classed among the heroes of France; delighting in bold enterprises, and aspiring after fame by splendid and extraordinary actions. These qualities, however, had they not been united with others, more solid and useful, though not so dazzling, would, perhaps, have prevented his sovereign from making choice of him on this occasion. But he was no less distinguished for sagacity and presence of mind, than for zeal and enthusiasm. To this nobleman the defence of Metz was intrusted; and he received the commission with joy. His zeal and enthusiasm were hardly necessary to induce many others of the French nobility to offer their services, so that Metz soon saw within its walls, some of the best blood of France, which, if necessary, would be most cheerfully shed to preserve it to the French kingdom. As soon as the Duke of Guise entered the place, he carefully examined it; it was of great extent, ill fortified, and the suburbs large. These defects, therefore, it was absolutely necessary immediately to remedy. For this purpose, the Duke ordered the old fortifications to be repaired with all possible expedition, even assisting and animating the labourers by his example. The officers and soldiers thus encouraged, cheerfully submitted to the most severe toil. After repairing the old fortifications, the Duke directed his skill to the erection of new ones. The suburbs were levelled to the ground, in order that they might not favour or protect the approaches of the enemy; and with a similar object in view, he gave orders that the country, for several miles round, should be laid waste. At the same time, he filled the magazines with provisions and military stores, and compelled all useless persons to leave the place; yet such were his popular talents, and his power of acquiring an ascendancy over the minds of men, that the citizens not only refrained from murmuring, but seconded him, with no less ardour than his soldiers, in all his operations; even in the ruin of their estates, and in the destruction of their public and private buildings.

In the mean time, Albert of Brandenburgh entered Lorraine, with 30,000 men, seemingly with an intention to join the French. The emperor, notwithstanding the vicinity of this army, and the advanced season of the year, for it was now the month of October, resolved to lay siege to Metz, contrary to the advice of his most experienced officers. One of his first attempts was to secure the co-operation, or at least the neutrality of Albert. He affected, by coming up to his price, and he joined the imperial army. The emperor now flattered himself that Metz would be soon reduced; but he was most lamentably mistaken. The winter set in with unusual rigour, in little more than a month from the commencement of the siege. The imperial camp was exposed to almost constant alternations of snow and rain, which, of course, produced disease even among the hardy Germans; while the Spaniards and Italians,
acclimated to more genial climates, were rendered still more sickly and ineffective. In vain the generals and officers endeavoured to animate and rouse their men; their exertions, their threats, their example, scarcely produced any effect. When they were ordered to advance to the assault, they remained motionless and silent. The emperor, blinded by his obstinacy to the cause of this conduct in his soldiers, retired to his tent, complaining that he was deserted by them, and upbraiding them with indiscretion or cowardice. In vain did his generals endeavour to persuade him to give up the hopeless and fatal enterprise; in vain did they represent to him, that he was his own enemy, in weakening and dispiriting that army, which, though it was not equal to the task of reducing Metz, so defended, at such a season of the year, might yet, if not totally destroyed in organization, strength and spirit, be adequate to the achievement of such conquests as would compensate for the loss of Metz. Charles was still obstinate, even when he must have lost all hope; nor did he raise the siege, till after the lapse of 65 days, spent in fruitless efforts, and after the loss of 35,000 men. Not withstanding this, the army was very near falling into his power, by a conspiracy of monks. The superior of the cordeliers of that city was a man of a bold and intriguing spirit, and warmly attached, either from habit, or principle, or interest, to the cause of the emperor. This man, by his address, had contrived to insinuate himself into the good graces and confidence of the governor, and then treacherously formed a design to deliver up the town to the enemy. The monks of his monastery being privy to his plan, he introduced into it a number of soldiers disguised as cordeliers, who were to open the gates to the garrison of Thionville. The plot was so well concealed, that it was not discovered or suspected till the very day on which it was to be executed. On its discovery, the superior was condemned to death, with twenty of the monks. Before the sentence was to be carried into effect, the criminals were put into a cell, for the purpose of confessing one another; and in this place they murdered the superior, and beat to death five of their brethren, who had been chiefly instrumental in effecting the rest.

When, at length, Charles found himself under the painful necessity of raising the siege of Metz, A.D. 1553, his army resembled rather an assemblage of worn out, diseased, and undisciplined people, than those troops which he had always been accustomed to bring into the field, and with which he had advanced against this place. He was compelled to abandon a large proportion, who were utterly unable to keep up with the main body, on account of their debility; while others, no longer under discipline, fell behind, either for the purpose of plunder, or to throw themselves into the hands of the enemy, from whom they expected the infliction of less misery than they had suffered during this unfortunate siege. Under these circumstances, the Duke of Guise might easily and safely have increased the disorder and the loss—perhaps have pressed on, almost to utter destruction, the army of his opponent: but either from motives of policy, or from the influence of humanity, he did not take all the possible advantages of his success. On the contrary, his attention and care were almost exclusively directed to heal the wounded, and restore the famished; and those who recovered, he sent home, under a safe escort, and with money to bear their charges; so that the courage and skill which he had displayed during the siege were paralleled, if not exceeded, by his humane treatment of his prisoners.

The misfortunes of the emperor were not confined to Germany. In Italy, the Sienese threw off the imperial yoke; and the fleets of Solymans, the ally of the King of France, struck consternation into the city of Naples; so that, had the latter been able to have invaded Italy at this juncture, it is probable he might have regained his footing in that country.

The disgrace which his army had suffered before Metz, sunk deeply into the bosom of Charles; and he resolved to wipe it away by a more powerful effort. For this purpose he invaded France, with a numerous and well appointed army, and laid siege to Terouanne, the fortifications of which were out of repair. It was, however, defended with great courage by D'Esse; but after his death, the Imperialists pressed the siege with increased vigour, and it was soon taken by assault. Charles immediately ordered the fortifications to be raised, and the inhabitants to be sent into the neighbouring towns. He then hastened his army, which he had placed under the command of Emanuel Philebert, the Duke of Savoy, towards Heslen, which was also carried by assault, though Henry had warned the town of its danger to its relief. Charles, however, carefully avoided an engagement; notwithstanding the French threatened to lay siege to Cambray, and the latter were under the necessity of retiring without accomplishing the object for which they had advanced.

In A.D. 1554, Henry beheld his rival's power, already too powerful for the repose of France, still farther augmented, by the marriage of his son Philip with Mary of England. But this event only served to increase the jealousy, without intimidating the King of France. He immediately augmented his forces, and resolved, by carrying on the war in Italy and the Low Countries at the same time, to compel the emperor to listen to equitable terms of peace, before the English sent any large reinforcements to him. Three large armies were accordingly equipped, with which he invaded and laid waste the provinces of Hainault, Liege, and Artois, reduced Marienburg, took Antwerp and Bouvignies by assault, and invested Ronti. Charles was now drawn down by years, fatigue and illness; yet, on hearing of the rapid march of the French, he put himself at the head of his army, and advanced to the relief of Ronti. Henry did not avoid the conflict; an obstinate skirmish took place. The imperial army suffered the loss of a considerable number of men and artillery. The Duke of Guise behaved in a manner worthy his reputation; and had the constable Montmorency acted with skill, vigour, activity, and courage, it is highly probable that the imperial army would have been completely routed; but the latter was jealous of the talents and fame of the Duke, and, influenced by these dishonourable motives, he would not second his efforts. The consequences were, not only that the imperial army escaped with comparatively little loss, but the French themselves were soon afterwards under the necessity of retiring. Charles was not slow in taking advantage of these circumstances. Immediately on the retreat of his opponents, he entered Picardy, where he retaliated the ravages which the French had committed in Hainault, Artois and Liege.

In Italy, the French were equally unfortunate: their unfortuunate army there was placed under the command of Strozzi, in Italy, a Florentine exile, who was defeated with the loss of 4000 men, in the battle of Marciano, by the Marquis of Marignano, general to Cosimo de' Medici. The Imperialists, fully sensible of the advantages that might be reaped from this defeat, immediately laid siege to Siena,
which was garrisoned by French troops, under the command of Montluč. This commander did all in his power to protract the loss of the place; for 10 months he defended it with the greatest gallantry; nor is it likely that it would ultimately have fallen, had it not been for the ravages which famine committed among the garrison. The Imperialists did justice to the valour of the besieged, in the terms which they granted to them, Montluč, with his French troops, being allowed to march out with all the honours of war.

In Piedmont, Henry was more successful. His army there was under the command of the Marshal Brisac, who was opposed to the Duke of Alva. Notwithstanding the great talents of his rival, and the equally discouraging circumstance, that his troops were inferior in numbers to the Imperialists, he not only dismissed the Duke, who had boasted that he would soon compel him to retreat into France, but he even penetrated into that part of the country which the emperor had hitherto preserved; and, in all probability, would have extended his incursions farther, had not the jealousy of the Guises and the Constable Montmorency operated in cutting off his supplies.

About this period the Emperor had come to the determination of abandoning his throne, and spending the remainder of his days in retirement. To this determination he was probably led by witnessing the decline of his military glory, and by having felt the weight of age and disease. He was also disappointed in the death of Pope Julius III, and the election of Cardinal Caraffa to the pontifical throne. The new pontiff, who assumed the name of Paul IV, immediately demanded the protection of the French, affirmed the investiture of Naples to Henry, and used every endeavour to negotiate a strict alliance with him. This alarmed Charles, and probably hastened his resolution to resign his dominions. Before, therefore, he left the Low Countries for Spain, which he had fixed upon as the place of his retreat, he took some steps towards a peace with France. The great bar against such a pacification, on the part of France, was the treaty which Henry had just concluded with the court of Rome. An expedition was therefore proposed of terminating their hostilities by a truce for five years, during which period, without discussing their respective pretensions, each should retain what was in his possession. Still, however, Henry was embarrassed by his treaty with the Pope; but the Constable Montmorency represented to him the imprudence and injustice of sacrificing the undoubted and real interests of his country to any rash engagements into which he might have entered; and this representation, with an express stipulation that the Roman pontiff should be included in the truce, removed the doubts and scruples of the French monarch.

As soon as Paul IV, was informed of the truce between Charles and Henry, terror and astonishment, mixed with rage and indignation, took possession of his breast; but it was necessary to conceal his emotions and feelings, as the Duke of Alva was already encamped on the frontiers of the ecclesiastical territories. Paul, therefore, in order to avert the immediate danger, affected highly to approve of the truce, and he even offered his mediation in order to bring about a permanent peace. Under this pretence, he sent Cardinal Rebiba, as his nuncio, to the court of Brussel; and his own nephew, Cardinal Caraffa, to Paris. To these were given private as well as public instructions; the latter, of course, were entirely pacific, and answering to his professions and avowed wishes; while, by the former, Cardinal Rebiba was directed to protract his negotiation as long as possible; and Cardinal Caraffa was empowered to urge the King of France to renounce the treaty, or to elude its engagements, and to renew his alliance with the court of Rome. The Cardinal was by no means unacquainted with the feeble and yielding parts of Henry's character: he knew that he was entirely under the guidance and influence of his queen, the Guises, and his mistress Diana of Poitiers: to these, therefore, he applied; and having gained them by his address, they easily swayed the king, who already leaned to that side towards which they wished him to incline, his own genius, warlike and enterprising, his habits and his hopes, that the successor of Charles would be a less formidable rival, strongly urging him again to try the fate of war. The only person of consequence in the French court, who opposed the measures of the Cardinal, the influence of the Guises, the queen, and Henry's mistress, and the secret wishes of the monarch himself, was Montmorency; but his efforts and remonstrances were unavailing. The broken by nuncio, by powers from Rome, absolved Henry from his oath, and he signed a new league with the Pope.

Paul, as soon as he learnt the success of his intrigues, immediately threw off the mask, and no longer professed himself the friend of peace, or the mediator between the monarchs; on the contrary, he ordered the Spanish ambassador to be imprisoned; he excommunicated the Colonnas, because they were attached to the cause of Philip; and when that monarch received this noble family in his dominions, the Pope proclaimed him guilty of high treason, and to have forfeited his right to the kingdom of Naples, which he was supposed to hold of the Holy See. Against those proceedings of the sovereign pontiff, the superstitious education of Philip I had first prevented him from proceeding in the manner in which a regard to his own dignity, and to the interests of his kingdom, imperiously demanded; but as the arrogance and hostility of the Pope were only augmented by the moderation and superstitions reverence which Philip displayed, that monarch at length resolved to adopt a more vigorous and determined line of conduct; and the Duke of Alva was commanded to enter the ecclesiastical territories. No sooner had the light troops of his army reached the gates of Rome, than Paul proposed a cessation of arms. To this, Alva consented; and a truce, first for 10, and then for 40 days, was concluded.

Henry entered on the new war with great alacrity and vigour. A numerous army, well appointed, was placed under the command of the Duke of Guise, who was ordered to lose no time in crossing the Alps, and advancing into Italy. This he accordingly did, A. D. 1557. As soon as the Pope heard of the advance of this powerful army, he threw aside all disguise; breathed nothing but war and revenge; and became more arrogant than ever. He probably judged not so soon as he had displayed his real character and wishes, had not the Duke of Alva judged it prudent to leave the papal territories, and advance to the protection of Naples, against which it was supposed the Duke of Guise would direct his more immediate and principal efforts. But the latter, though he had been eager for the war, and hoped to measure his talents against the Spanish commander, soon found that he should be able to achieve nothing of importance. The Pope, though so indignant against Philip, had neglected to raise both the pecuniary and military aids, with which he had engaged to supply the French when they entered Italy, and the
No sooner had Philip learnt that the King of France had been induced, by the intrigues of the Pope, to break the truce, than he resolved to penetrate into that kingdom, and, by one vigorous effort to convince Henry that he was not to be thus treated with impunity. With this object in view, he assembled in the Netherlands a body of 50,000 men. He exerted his influence over his consort, Mary of England, so successfully, that, notwithstanding the repugnance of her subjects, she declared war against France, and sent 10,000 men to assist his projects against that country; and he gave the command of his army to Emanuel Philibert, Duke of Savoy, one of the greatest generals of that age. Philip himself fixed his head-quarters at Ambray, while the Duke, after having kept the French for a considerable time in utter ignorance of his views and destination—threatening Champagne till he succeeded in drawing all their troops in that direction—suddenly marched to the right, and invested St Quintin in Picardy. This was a place of considerable strength, but its fortifications had not recently been put in a state of repair, and a large portion of its garrison had been drawn off towards Champagne. It is probable, therefore, that it must soon have surrendered, had not Admiral Coligny taken the gallant resolution of throwing himself into it, with such troops as he could suddenly collect for that purpose. This he accomplished, notwithstanding all the circumspetion and efforts of the enemy, breaking through their main body with 700 horse and 200 foot. To this hazardous step the admiral was probably incited, from the consideration that the town was within his own immediate jurisdiction. Henry was fully sensible of the importance of preserving it, as, if the enemy succeeded in taking it, the road to Paris was nearly quite open to them. He therefore hastily assembled a small body of troops, not half the number of the army which was besieging it, and gave the command of them to the Constable Montmorency. This general had hitherto been distinguished, not less by his prudence and caution, than by his skill and bravery. On this occasion, however, anxions to extricate his nephew, he conducted himself with fatal rashness. At first, indeed, his attempt to relieve the town was attended with success, for, by approaching the camp of the enemy, the brother of Coligny, with 500 troops, was enabled to force his entrance into the town. Here, however, his success ended; for, in the execution of this design, Montmorency had drawn too near the entrenchments of the besiegers. The Duke of Savoy, always on the alert, took advantage of this circumstance; and, as soon as the French general began to retire, he pressed on him with superior numbers. In vain did Montmorency use his utmost endeavours to keep his men firm and in order. The Count Egmont, at the head of the Duke of Savoy's cavalry, made a furious charge, which the French could not withstand; their ranks were broken; and their men at arms, who had hitherto displayed the most cool and determined courage in the midst of the most imminent danger, sought shelter in a precipitate and disorderly flight. As soon as the horse gave way, the foot, who had depended on them for support and protection, were wrecked. A second charge decided their fate; they also fled in the utmost terror and confusion. Above 4000 perished in the field; and the Constable himself, after in vain endeavouring, by his example and exertions, to reanimate his troops, and to put a stop to their flight, having received a dangerous wound, was made prisoner, along with the Dukes of Montpensier and Longueville, and the Marshal St Audre.

Such was the result of the famous battle of St Quintin, which was fought on the 10th of August 1557. The intelligence of it spread consternation and terror through France, almost to as great a degree as the battles of Cressy and Agincourt. Already it was apprehended that the enemy were approaching Paris; the inhabitants of which prepared to quit it. In this period of general dismay, the firmness and presence of mind of Henry were conspicuous, and highly beneficial. He betrayed no alarm; he refused to admit the idea of danger; on the contrary, he exerted himself to repair the loss which he had sustained, by the most prompt and vigorous measures. The Duke of Guise was instantly recalled from Italy; the assistance of the Grand Signior was solicited; the Scots were invited to invade the North of England, for the purpose of drawing off the English troops to the protection of their own territory. The ban and arrisban of the frontier provinces were called out; and, in short, every measure was taken which could operate towards the weakening or distraction of Philip's forces, or the protection of France. When we consider, however, the power of Philip, the consternation which pervaded France, and the great loss which she had sustained in the battle of St Quintin, it may well be doubted whether all these precautions and efforts would have been availing, had Philip pursued with alacrity and vigour the advantages which he had gained. But he refused to listen to the advice of the Duke of Savoy, who strongly and wisely urged, that, overlooking all inferior and intermediate objects, they should march, without the smallest delay, by the shortest route to Paris. The cautious temper of Philip, afraid of committing his forces in the heart of France, without a single place to retreat to in case of disaster, strongly objected to this plan; and he asked the opinion of his other generals. They, easily ascertaining how their monarch was inclined, recommended that the siege of St Quintin should be continued, which, it was supposed, could not now hold out many days. In this expectation they were disappointed. Coligny, fully sensible that the fate of France probably depended on his holding out till Henry had prepared sufficient means to oppose the progress of the enemy towards Paris, put forth, in a most wonderful and successful manner, all the resources of his great talents and long experience. For 17 days, he baffled the repeated assaults of the Spaniards, English, and Flemings; at length, overwhelmed by superior numbers, the town was carried by storm, and Coligny himself was taken prisoner on the breach. St Quintin was St Quintin thus taken; but by this time it was no longer prudent to advance into France, and Philip became sensible that he had lost an opportunity that could never be recalled. he therefore contented himself with reducing the petty towns of Honfleur, Coutent, and Noyon, which, with St...
Quentin, were the sole fruits of one of the most decisive victories which had been gained in the 16th century.

The earliest account of the fatal blow which France received at the battle of St Quentin, was carried to Rome by the courier whom Henry dispatched to recall the Duke of Guise. In vain the Pope remonstrated against the departure of the French; the orders sent to the Duke were peremptory, and admitted of neither modification nor delay. Paul, therefore, was obliged to have recourse to the influence that he knew he possessed, from his character and situation, over the mind of Philip, in order to avert the danger to which he was exposed; and so well did he work on the superstition of the Spanish monarch, that, on his agreeing to renounce his league with Henry, Philip, on his part, stipulated that the Duke of Alva, the proudest man of his time, should repair in person to Rome, and after asking pardon of the Holy Father in his own name, and in that of his master, for having invaded the patrimony of the church, should receive absolution for that crime. On the very day on which the Duke of Alva made this humiliating submission to the Pope, the Duke of Guise left Rome on his return to France. Here he was received as a protecting angel, and immediately appointed lieutenant-general of the kingdom. The army which was placed under his command, was numerous and well appointed, reinforcements having arrived from Germany and Switzerland, and a new levy being raised from various parts of France. The troops partook of their general's wish and determination to wipe off the disgrace, which their country had suffered from the defeat of St Quentin; but the Duke of Guise kept his plan a profound secret. He put his army in motion in the middle of winter, and at first menaced the frontier towns of Flanders; thus, having deceived the enemy by false marches, he suddenly laid siege to Calais. This place, for upwards of 200 years, had afforded the English an open passage into France. Notwithstanding its importance in this point of view, and that it was the only town which the English retained of their ancient and extensive territories in this kingdom, they usually withdrew almost the whole garrison at the end of autumn, and the ministers of Mary had greatly neglected the works. Some of them, indeed, were so confident as to say, that if Calais were attacked during the winter, they would undertake to defend it with their white rods. The Duke of Guise, aware of the badness of its fortifications, and the inadequacy of its garrison, suddenly invested it, drove the English from the forts which protected it, and in eight days made himself master of a place which Edward III. could not take in less time than 11 months. Henry, in order to secure this important conquest, expelled the English inhabitants, and enticed his own subjects to settle there, by granting them several important privileges and immunities.

In the spring of 1558, the Duke of Guise advanced against Thionville, which capitulated after a siege of three weeks. In the mean time, the Marshal de Termes, who had been appointed governor of Calais, penetrated into Flanders, stormed Dunkirk, and advanced against Nienpoort. While he was before this place, the Count of Egmont approached to its relief. De Termes was not only inferior in numbers to his opponent, but he was also encumbered with his spoils; he therefore resolved to retreat, but the latter circumstance rendered his retreat slow and difficult. The Count of Egmont, on the contrary, pursued, with very great activity, and overtook the French near Gravelines. De Termes finding a battle unavoidable, prepared to defend himself with great courage. For some time, notwithstanding the great disparity of the forces, victory was doubtful; till at last chance, on this, as on many other occasions, decided the fate of arms: A squadron of English vessels, which chanced to be off the coast, on hearing the cannon, entered the river Aa, and turned their guns upon the right wing of the French army, which were dispirited by this unexpected circumstance, while the Flemings were equally encouraged. The former fled in great disorder; about 2000 were killed on the field of battle; a greater number in their flight were put to death by the peasantry; and the general, with a number of officers of distinction, was taken prisoner. This disaster obliged the Duke of Guise to relinquish all his other schemes, and to hasten to the frontiers of Picardy, to oppose the progress of the enemy. About the same time, the Duke of Savoy effected a junction with the troops under the Count of Egmont. As soon as these junctions were respectively formed, Philip and Henry put themselves at the head of their armies, each commanding about 40,000 men; and being encamped at the distance of a very few leagues, an awful and decisive crisis seemed approaching. But both the monarchs were weary of war; it had answered the expectations of neither, while, for half a century, it had exhausted their respective kingdoms. Philip was anxious to visit Spain; and therefore was disposed to listen to pacific overtures. The motives and objects which inclined Henry to meet the views of Philip were more complicated. He was eager to put an end to the progress of heresy in France. His mistress, the Duchess of Valentinois, had long regarded, with disgust and displeasure, the haughtiness of the Duke of Guise, and of his brother the Cardinal of Lorraine; and, above all things, wished to oppose their measures, and diminish their influence and popularity. This she could not expect to accomplish, so long as the Duke had an opportunity of adding to his military fame. Peace, therefore, she was bent on bringing about; and, by her persuasion, Montmorency, who was eager to regain his liberty, undertook the intricate and difficult negotiation, and the Abbey of Cercamp was fixed upon as the place of congress; the conferences were afterwards removed to Chateau Cambresis, where, in 1559, a definitive treaty was signed. By this treaty, France restored to the Duke of Savoy the territories which she had taken from him in Piedmont, Savoy, and Bresse. Corsica was given up to the Genoese. Haden, Catelet, and Noyon, were restored to the French, who were also suffered to retain Calais, Metz, Toul, and Verdun. A separate treaty was, at the same time, signed between the King of France and Elizabeth, who now sat on the throne of England, by which the former engaged, at the expiration of eight years, either to deliver up Calais, or to forfeit the sum of 50,000 crowns.

In order to facilitate and hasten the conclusion of peace between Spain and France, the Constable Montmorency negotiated two treaties of marriage; one between Elizabeth, the eldest daughter of Henry, and Philip; the other between Margaret, Henry's eldest sister, and the Duke of Savoy. The part which Montmorency took in all these arrangements, gave him great weight with the king; while, on the other hand, the family of the Guises, fully sensible that their influence was on the decline, and that, during a period of peace,
they would possess no opportunity of compensating for the diminution of this influence, by gaining military renown, and increasing their influence with the nation, arranged the treaty in the most open and indecent manner, as dishonourable and disadvantageous to France. But Henry attended not to their complaints; he was too much occupied, either with the Duchess of Valentinois, who continued to countenance and support Montmorency, or with taking measures for the suppression of heresy. Among the most illustrious prosetyes to the doctrines of Calvin, was D'Andelot, the brother of Coligny, and the nephew of the Constable. So deeply impressed was he with the truth and importance of the opinions that he had embraced, that he dared to avow them in the presence of his sovereign. He was immediately deprived of his post of general of French infantry, committed to close confinement, and restored to liberty only on submission, and through the entreaties of his uncle. So bigotted and blind was the zeal of this monarch, that he attempted a prosecution of the Duchess of Ferrara, daughter of Louis XII, who granted an asylum in her court to the literati, who were tinctured with heterodoxy; ordered the judges to cause all to be arrested as heretics, who should solicit them in favour of those who were condemned to death on account of their religious opinions; and denounced throughout the capital and the different provinces, his firm determination to root out heresy by the most severe and violent persecution. But these plans of Henry were happily interrupted by his death. The Duke of Savoy had arrived at Paris to espouse the king's sister. Jousts and tournaments were ordered on this occasion: in these dangerous exercises Henry excelled. After having broken many lances with success, on the last day he was desirous of breaking a lance with the Count de Montmorenci. The shock was rude on each side; but the count's lance breaking against the helmet of the count, the latter attacked Henry with the stump, which entering his eye, the monarch fell senseless on the ground. He remained in a state of insensibility for eleven days, and then expired, in the 16th year of his reign, and 45th of his age. By his queen, Catharine of Medicis, he left four sons; Francis, who had been married, a few years before his father's death, to Mary queen of Scotland; Charles, Alexander, and Hercules. The names of the two last were afterwards changed to those of Henry and Francis. He also left three daughters; Elisabeth, queen of Spain; Claude, duchess of Lorraine; and Marguerette, who was first queen of Navarre, and afterwards queen of France. In some respects, the character of Henry resembled that of his father: like him, he was courteous, open, unsuspicious, and beneficent; fond of pleasure; handsome in his person, and accomplished in the martial exercises of the age; but he possessed not either the capacity or the discernment which distinguished Francis; and he was naturally so tractable and yielding, that he was almost constantly under the guidance of his favourites.

Francis II. A.D. 1539.

Francis II. was only 16 years of age when he ascended the throne of France. His mind and body were alike feeble, so that he was completely under the influence of those who surrounded him. Unfortunately there were about him persons not more remarkable for their talents, than from their intrigues, ambition, and vices. His mother, Catherine of Medicis, was a woman, bold, enterprising, sagacious; whose firmness and presence of mind were never awed or disconcerted by the most formidable or unexpected dangers. Her penetration was equally remarkable; and it was accompanied by a greater degree of comprehension than usually attends that quality. Thus powerful in her mental endowments, she was not less distinguished by her manners. When her interest, or particular circumstances required it, she could be mild and insinuating; and she often appeared to gain her point, by courting those from whom she expected any favour or sacrifice, when in fact they were the dupe of her superior artifice, or actually bent before her commanding powers of mind. Her disposition was magnificent, her profusion excessive; but she was magnificent and profuse only to answer her own purposes, which, however, had frequently all the characteristics of greatness, except justice. Of the arts and sciences, even amidst the horrors of war, she was the liberal and dignified patroness; and in the patronage with which she nourished and favoured them, there was so much discrimination and knowledge, that she most effectually accomplished her object. Even to men of learning, notwithstanding her political and religious bigotry, she was a generous patroness. In short, in her might clearly be traced many of those features, both of mind and manners, which characterised the most distinguished branches of the family from which she was sprung. But these grand, and even attractive qualities, were strangely intermixed and debased by her vices and prejudices. To accomplish her views, she did not scruple to overlap the bounds of justice, truth, and humanity. She was cruel, rapacious, and deceitful; it would even seem, from some parts of her conduct, that her cruelty was so refined and disinterested (if that expression may be allowed), that it centered in itself, nor looked to any exterior object, as its own justification or excuse. In her morals, she displayed all the profligacy of her nation; her ambition was without bounds; it did not even confine itself to objects grand and comprehensive in their nature, but could, at times, feed on what was comparatively trifling and insignificant. Such a woman, even if she had not stood in the relation of mother to the young king, must have possessed great influence over his mind; and even during the life of her husband, she had been preparing herself for the exercise of power. No person was more deeply sensible of the importance of the maxim, of dividing in order to govern; and no person ever acted more systematically on that maxim.

She soon had occasion to act on this maxim; for the weakness of Francis afforded opportunity for intrigue, and opened the way to the rule of the kingdom. The family of the Guises were perhaps next to Catherine de Medicis, most distinguished at this period for their talents and ambition: there were five brothers of them. The Duke of Guise himself; the Cardinal of Lorraine; the Duke of Aumale; the Cardinal of Guise; the Marquis of Elbeuf; and the Grand Prior: they were all men of great ambition, and who employed the greatest military and political talents, in order to acquire the highest power in the state. As they were uncles to the Queen of Scotland, and had negotiated the marriage between her and Francis, they had easy access to his person, and great influence over his mind and feelings; nor were they without considerable influence with the mass of the nation. The Duke of Guise himself was regarded as the saviour of France by the deeds which he had performed, when he was recalled from Italy; and if these left any doubt respecting his military talents and skill, they were completely removed by the recollection of his defence of Metz. But he trusted for his popularity, not merely to what he had achieved as a soldier; for...
to military talents he united a wonderful degree of humanity, courtesy, and liberality: at that period, when the great bulk of the people were either entirely overlooked, or considered and treated as beings of an inferior order and description, he condescended not only to notice them, but even to excite their attention and gratitude, by his marked attention to their interests, and even to their feelings and prejudices. He was not less distinguished by his zeal for religion, than for the talents and manners which we have described: and this zeal was so ardent and overpowering, that it even conquered his natural humanity of disposition and courtesy of manners. Such was the Duke of Guise himself; but his character, or at least his conduct, was considerably modified by the influence which his brother the Cardinal Lorraine possessed and exercised over him. Even in those days of high church authority, and of rigid and unbending orthodoxy, this pretense was venerated by the clergy, as the guardian of their rights and privileges, and by the Catholics as the champion of their faith. His talents were perhaps more varied than those of his brother, since he was eloquent in debate, fruitful in expedients, and versed in all the intrigues of the court; but, on the other hand, he was too readily depressed by defeat, and too easily elated by success. His personal courage was not inferior to that of the Duke's; his temper was vindictive; his morals most dissolute.

The Constable Montmorency and his family were opposed to the family of the Guises, not more in views and interest, than in character. The constable himself was of a haughty and inflexible disposition, and would not condescend, like the Duke of Guise, to gain that influence, by the affability of his manners, which he thought ought to be the unsolicited reward, or rather consequence, of his high birth, great services, and undoubted talents. Nor was he, in other respects, better calculated for succeeding in the intrigues of a court: his notions of what was his duty, both in his public and private station, were strict, and utterly at variance with the loose and accommodating morality of the age and nation. In every respect he most conscientiously performed what his conscience dictated; and strict and severe to his own fallings, he had no moderation or excuse for those of others. It may well be conceived that, with such a character, and with such high ideas of his own dignity, merits, and deserts, his temper could not be flexible, nor his address insinuating. Though he regarded the highest offices of the state as his due, yet his pride would not permit him to solicit them; and he was still further excluded from them, by his open and warm attachment to the established religion.

Of the princes of the blood who next claimed our attention, Antony de Bourbon, king of Navarre, was of a disposition mild, humane, and easily wrought upon. His talents were by no means of the first order; nor had he compensated for deficiency of talents, by the acquirements of culture, or by habits of application to business. Indecisive and timid, he fluctuated between the reformed and Catholic religion; fond of pleasure; he forgot his political rights, duties, and engagements, in the arms of his mistresses. Such a man was ill calculated to take the lead at the court of France, while, on the other hand, he was admirably calculated to become the instrument of intrigue and ambition, with men more highly endowed than himself. His brother, Louis, Prince of Condé, laboured under the disadvantage of an ungraceful and diminutive person; yet such were the attractions of his manners and character, that he received from the ladies of the court of France, the most flattering proofs of their affection. His courage was undaunted; and though his income was narrow, yet his magnificence and liberality were great. His talents, though not perhaps of the first order, were by no means despicable; but what distinguished him particularly, was an attachment to the reformed religion, not merely ardent and zealous, but pure and enlightened. In vain were the allurements of pleasure, and the higher and more splendid rewards of ambition, employed to entice him from his religious principles and professions: he was firm and unyielding; and when they called upon him for action or sacrifice, he was always ready. To the Duke of Guise he was an open and formidable rival, not more from the similarity of their character and objects in some respects, than from the opposite religious sentiments which they respectively embraced.

The Admiral Coligny was brave, generous, and sincere. His first and most darling wish was, to secure liberty of conscience for himself and his brethren of the reformed religion. Could he have secured this, he would willingly have withdrawn himself from public life; but while this was unattained, he regarded it as his paramount duty to stand forward, as the undisguised and enthusiastic champion of what he was convinced was the truth.

The deputies of parliament waited on Francis, soon after his ascending the throne, to express their duty and allegiance to his person; on this occasion he informed them, that he had thought proper to assign to the Duke of Guise the supreme administration of the military department, and to the Cardinal of Lorraine the supreme administration of the finances, at the same time the Constable Montmorency was dismissed from his office of master of the household to his seat at Chantilly; and the King of Navarre, with his brother the Prince of Condé, were received at court in a cold and disrespectful manner. The former was soon afterwards persuaded by Catherine de Medicis to leave Paris, and to take up his abode in Bearn, under the vain hope that he might recover his former dominions by negotiation.

As soon as the King of Navarre had left Paris, the measures and plans of the Guises and Catherine began to unfold themselves. An edict was published, forbidding any person to carry fire-arms, or to wear any dress favourable to the concealment of such weapons. Another regulation was adopted, which declared that no person should hold two situations at the same time. The object of this was undoubtedly the Admiral Coligny, who immediately resigned the government of Picardy, which was given to the Marshal Briseis, notwithstanding the Prince of Condé endeavoured to obtain it. The Duke of Guise, at the same time, was appointed Master of the Household.

As all these measures were preparatory to the persecution of the Protestants, it may be proper to take a retrospective view of the origin and progress of the reformed religion in France under Francis I. As has been already noticed, the new doctrine had spread greatly at court, as well as in the capital and provinces. The Christian Institutes of Calvin were dedicated to that king. His sister, the Queen of Navarre, protected his disciples, while they were persecuted by the clergy and the parliament. The spirit of the new religion was increased and invigorated, and the numbers who professed it were greatly augmented, by the massacre of Ca-
bribery and Merindol, and by the executions which were
imprudently multiplied by Henry II. Thus, at the
accession of Francis II. Calvinism had gained a firm and
wide-footing, and could count among its professors, se-
veral men of great talents and influence, Admiral Col-
igny, and his brother D'Andelot, and Cardinal Chatil-
on, were firm friends to a reformation; and the Prince
of Condé inclined to the same side. The court, on
the contrary, seemed resolved to crush the Calvinists, by
the most open and violent measures. Instead of cor-
recting the errors, which had given offence, even to
conscientious Catholics, new observances still more su-
perstitious were enjoined. Images of the Virgin, and
of the saints, were placed at the corners of the streets,
with tapers lighted up before them; round these, the
populace assembled, singing hymns, and compelling the
passengers to put money into little boxes, for the ex-
 pense of the illumination. If a man did not bow to
these images, and stop with marks of reverence, while
the people were paying this worship, he was either
knocked down, dragged to prison, or insulted. These,
however, were trifling evils, to which the Protestants
were exposed. Courts of ecclesiastical judicature, in-
vested with inquisitorial powers, were erected, denom-
nated Chambres Ardentes, from the severity of their pu-
ishments. To these the cognizance of heresy was en-
trusted. The strictest search was made to discover of-
fenders; and as the Protestants, in order to conceal
themselves, were obliged to meet by night, they were
charged with committing in these assemblies the most
dreadful crimes. Thus goaded on to resistance, they
only waited for a fit opportunity and season to protect
themselves by force of arms; and this was soon sup-
plied them by the mixture of folly and wickedness
which the court displayed. In consequence of the
peace, great numbers of troops had been disbanded,
without receiving what they conceived due for their
services. They therefore came up to Paris, and applied
to the Cardinal of Lorraine, as Minister of the Finances.
He treated them with insult, unwilling or unable to
satisfy their demands; and when they again importun-
ated him, he commanded them to retire, on pain of be-
ing instantly hung upon a gallows, which he had or-
dered to be erected for that purpose. By this foolish
and harsh behaviour, these soldiers were totally alien-
ated from the house of Guise, to which the military ta-
lents and success, as well as the popular character of
the Duke, had hitherto attached them; and they uni-
ited themselves with the Protestants.

Soon after this, the conspiracy of Amboise was for-
med. Of this the Prince of Condé was the invisible mas-
erolet. And Renaudie, a Protestant gentleman, the open
adversary author. The latter was a man of ancient fami-
ly, but of ruined fortune; he had lost a law-suit, and
been condemned to banishment for having produced
fictitious titles. At Geneva and Lausanne, he imbibed
the doctrines of the Reformation; and afterwards, un-
der a feigned name, he traversed the different provin-
ces of France, for the purpose of rousing the Protestants
against the Duke of Guise. At length he appointed a
general rendezvous at Nantes, where the parliament of
Brittany was at that time sitting; and above 200 gen-
tlemen of fortune and family, from various parts of the
kingdom, attended the summons. Before they laid
open his plan for carrying off the Guises from Amboise,
where the Court then resided; to set the Prince
of Condé at the head of affairs, and to secure liberty
of conscience. The day was fixed for the execution of
this design, and the measures so well concerted, that
its success appeared infallible. But while thousands of
conspirators kept the secret, it was betrayed by an ad-
vocate, who, though a Calvinist, yet regarded the plot
with horror. As soon as this information was received
at court, the Duke of Guise was appointed lieutenant-
general of the kingdom, with supreme power in all ca-
es, civil and military. Renaudie, though he rather
suspected, from the precautionary measures adopted by
the court, that his plan was known, resolved to perse-
vere in its execution; and several small bands of con-
spirators, marching only by night, succeeded in reach-
ing, undiscovered, the gates of the castle of Amboise.
Here, however, they were repulsed, and cut to pieces
by the inhabitants, at the head of whom the Duke of
Guise had placed himself. The Baron of Chatelau, at
the head of a considerable number of Calvinists, shut
himself up in the castle of Noisy, where he was attack-
ed by the Duke of Nemours, to whom, on condition
that the lives of himself and his associates should be
spared, he soon surrendered himself. As soon as Re-
naudie was informed of the dangerous situation of Cha-
telau, he put himself at the head of a few men, as de-
spere as himself, with the intention of either rescuing
him, or perishing in the attempt. On the road he was
met by 200 cavalry of the opposite party. A most des-
perate action took place; but Renaudie's companions
being overcome by superior numbers, he rode up to
the commander of the cavalry, and thrusting a pistols
through his vizor, laid him dead upon the spot. He
himself was afterwards shot, and died fighting despe-
ately to the last. His body was publicly exposed on
a gibbet, and a label affixed to it, with the inscription,
Chief of the Rebels.

The fate of Renaudie produced not the effects which
the court expected. On the contrary, the Protestant
party increased in numbers, and displayed additional
zeal and activity. Still the Court adhered to their mea-
sures of rigour and duplicity. The Baron of Chatelau,
notwithstanding the assurances of safety which he had
received, was sacrificed to the implacable enmity of the
princes of Lorraine. Every temptation was held out to
him, to name the Prince of Condé as his accomplice;
but though a declaration to that effect had been extort-
ed from his companions, he firmly refused the asper-
sion, and to the last moment of his life, proclaimed the
innocence of the Prince of Condé.

This prince now thought himself called upon openly to
vindicate his honour, which he did in the presence of
the king; offering to maintain it, in single combat,
against his accuser. It could not possibly be mistaken
that he pointed at the Duke of Guise; but the Duke
eluded the challenge, warmly praising the conduct of
the prince, and offering to be his second against any
antagonist. In private, however, he strongly urged the
king to secure a chief, who was so formidable, on
account of his birth, talents, and enterprise. Francis,
could by no means yield to the suggestion of danger to
which he might be exposed from the intrigues of the prince,
seemed disposed to have listened to this advice; but at
this period, in consequence of the death of the Chancel-
lor Olivier, and the succession of Michael De l'His-
pital to that office, the power of the Guises suffered a de-
cline; for the new chancellor, being a man of cool tem-
per, great abilities, and a friend rather to his king and
country than to any of the parties which then endeav-
uoured to gain an ascendency over them, pointed out,
in the strongest manner, to the queen-mother, the dan-
ger of the family of the Guises acquiring a permanent
ascendency, and advised her to follow that temporising
system of policy, to which she was so naturally inclined by her disposition, and so happily adapted by her habits and talents. In consequence of this advice, Catherine lent her support secretly to the Prince of Condé and the Protestants.

At this time, the internal state of the kingdom was so overcast with danger, that it was deemed necessary to hold a general assembly at Fontainebleau, to deliberate on the exigencies of the state. At this assembly, the Admiral Coligny presented to the King a petition from the Calvinists, demanding the public exercise of their religion, and that their public meetings might no longer be imputed to them as a crime; adding, that although no name was affixed to it, yet, whenever his majesty would signify his pleasure, it would be signed by 150,000 persons. Montluc, Bishop of Valence, and Marilla, Archbishop of Vienne, spoke with energy against the abuses which occasioned so many troubles and disorders; exposed the vices of the court of Rome—the ignorance and corruption of the French clergy—the avarice of the Italians, who, without residing in the kingdom, possessed one-third of the benefices—the injustice of the persecution, which confounded the innocent with the guilty—and concluded, by stating it as their firm opinion, that the public calamities arose from the errors which had crept into religion, and from the vicious conduct of those who were its ministers. At the same time, while they, in this bold and liberal manner, advocated the cause of truth, and denounced the vicious and corrupt, they condemned _seditionis religiosae_, and insisted on the necessity of repressing and curbing them, marking the distinction, however, between those who, made religion a pretext for disturbing the state, and such as adhered to their errors from a principle of sincerity; the latter they thought it was wrong to treat as criminals. They even went farther, and pointed out, in clear and strong terms, the dangers which might arise from persecution. Opinions in themselves weak, thus acquired, in the view of the multitude, strength and importance. A curiosity to know, and often a desire to embrace them, was excited, when people saw them maintained in the midst of the flames, by men of estimable character and irreproachable morals. After again insisting on the necessity of a reformation, they concluded with proposing a national synod, if the Pope should refuse to convocate a general council, with a prohibition of exerting the severity of the law except against real crimes.

Coligny afterwards rose again, and in plain and manly language advocated the cause which he had conscientiously embraced. He then adverted to the guard which had recently been placed around the king, reminding his majesty, that in the affection and loyalty of his subjects he would always find the most faithful and brave defence; that nothing could be more prejudicial to his real interests, as well as to the interests of the nation at large, than that he should either be dread ed by his subjects, or the object of dread to them. He concluded, by repeating his opinion, that the king's guard should be discharged. The States-general assembled, and methods contrived to root out, not only speculative, but practical errors from the church. If these things were done sincerely and effectually, the king would regain the affections of his subjects, the nation would be peaceable and happy, and real religion would flourish and influence the conduct of all. This speech of the admiral, so much in character, called up the Duke of Guise, who purposely misrepresented the advice and wishes of Coligny, declaring, with much warmth, that no council should force or influence him to change his religion. The Cardinal of Lorraine followed and supported his brother, denying the imputations which Coligny had cast on the opinions and practices of the church, strongly insisting on the necessity and sacred obligation of exterminating error by the secular power, and branding as sinister the advice which Coligny had given. The opinions of the Guises would probably have been carried into full effect, had not Catherine of Medicis considered it as her best policy to check their violence, and to use her influence with the king to counteract, at least, the advice of Coligny and his party. Francis therefore declared his intention of convoking the states in the ensuing December, and thus breathing time was given to the Protestants.

It was evidently their policy to keep well with Catherine of Medicis; and this they could only effect by not alarming either her ambition or her religious prejudices; but unfortunately they conducted themselves in such a manner as to excite her hatred, and to induce her again to unite herself with the Guises: For the King of Navarre and the Prince of Condé concerted measures to deprive the Guises of their power and influence before the states assembled; and even laid a plan for surprising the city of Lyons. This plan reached Catherine, who, regarding it as proceeding from a spirit which looked farther than the mere overthrow of the Guises, took the alarm, and, by the interception of some letters, completely defeated the execution of it.

In the mean time, the period for the assembly of the states drew near. It had been originally appointed to be held at Meaux, but it was afterwards transferred to Orleans. Hither the King, now in a very dangerous state of health, proceeded, with a guard of 1000 caval rY. The King of Navarre, and his brother the Prince of Condé, were invited to attend, with the strongest assurances, not only that they should be safe, but that such measures would be adopted at this assembly as would satisfy them, and please the Protestants. At first they were suspicious of the machinations of the Guises, but at last they resolved to obey the summons. In the course of their journey, they were darkly and mysteriously informed of some danger that threatened them; but justly concluding, that if they discovered suspicion or alarm, or if they returned instead of proceeding, they might probably expose themselves to still greater risk, they resolved to go on to Orleans. Indeed, they beheld before, behind, and on all sides of them, parties of men stationed there under various pretences, but whom they had just reason to apprehend were instructed to intercept their retreat or flight.

When they arrived at Orleans, the king at first treated them with great coldness and indifference; but this behaviour was soon changed, and succeeded by the most violent reproaches, and such accusations as left them no doubt that they had acted imprudently in attending the assembly. Between the Duke of Guise and the Cardinal of Lorraine the king was seated; around him were the captains of his guards. On the prince of Condé he fixed a look as full of determination and meaning as he could well call up, and accused him of having attempted to seize on the principal cities in France, and even of having plotted to take away his life and that of his brother's. This accusation, so unexpected, and brought forward at a time and in a place which bespoke a determination to throw aside all regard to justice and innocence, by no means daunted the intrepid Condé. He protested that he was guiltless of
the crime laid to his charge, and he offered to prove his innocence. To this offer Francis replied, that it would be necessary to proceed by the usual modes of justice. On this, the King of Navarre was conducted to an adjoining apartment, where, however, he was allowed the liberty of conversation; but the Prince of Condé was strictly confined, and with such precautions plainly indicated that it was resolved to take away his life. The Protestants immediately took the alarm; but the Guises were afraid to proceed to extremities too suddenly; and the admiral, though he remained at Orleans, was un molested. His brother D'Audilot, some time before, suspicious of the treachery of the Guises, had withdrawn into Brittany.

The chancellor and five judges were appointed to interrogate the Prince of Condé in prison; but he refused to answer to their questions, and boldly demanded to be tried in the most public manner. This, he said, he claimed as due to his dignity and rank, not less than to his innocence. Catherine of Medicis, by whose advice, or at least with whose concurrence, the king had taken these steps, and who, at first, with her characteristic duplicity, affected to deplore the violence which she herself had consented to, soon discovered the error she had committed, in uniting herself too closely with the Princes of Lorraine, and in destroying that balance of parties most favourable to the success of her own intrigues, and to her own views and interest: But she had gone too far to recede; and the fate of Condé seemed inevitable, when he was preserved by the death of the king. Francis, on his return from the chase, was seized with a violent pain in his ear; in a short time an imposthume was formed, and the surgeons declared that nothing could save him. The Duke of Guise and the Cardinal of Lorraine thus beholding their power, in all probability, drawing to a conclusion, while the very same cause must preserve the life of their rival, hurried on the process in a most shameful and indecent manner, neglecting even the forms of justice. As the judges were entirely under their influence, they found him guilty without the slightest hesitation; and he was condemned to have his head struck off on a scaffold before the apartment of the king.

Before, however, the execution could take place, it was indispensably necessary that the signature of the chancellor should be put to the order for that purpose. De l'Hospital was a man always averse to violent measures; and in this case, as the king's death was expected every hour, he was reasonably afraid lest he should be called to account if he lent the authority of his official character to the execution of such an unjust and illegal sentence. The Guises in vain appealed to Francis; he was now too weak to understand what they wanted; and even while they were urging him to issue his orders to the chancellor to affix his signature to the warrant for their rival's death, he breathed his last. Thus was the Prince of Condé snatched from the very jaws of destruction. The character of Francis was not marked by any strong or discriminating features; nor could it indeed be expected, when we reflect on his extreme youth—on the manner in which that youth had been spent—and on the talents and intrigues of those by whom he was constantly surrounded, and who, however they might differ among themselves, took especial care that the king should never think or act for himself. His death opened up a new scene for intrigue and ambition; and so eagerly were Catherine and the Princes of Lorraine engaged in securing or extending their influence, that the funeral of the king was attended only by those who had been his governors, and by the Bishop of Senlis.

Francis II. was succeeded by his brother Charles IX. only ten years of age. The extreme youth of her son forbade Catherine an ample field for her powers of ambition and intrigue. She was resolved not to commit the management of Charles to any person, but to wield herself the whole machine of government; at the same time she was fully aware, that her power would not be secure or permanent, unless she acted on her favourite maxim, divide and govern. After, therefore, she had obtained for herself the appointment of guardian to her son, she directed her thoughts to the leaders of the principal parties in the state. The King of Navarre was named lieutenant-general of the kingdom; the sentence against Condé was annulled, and he was pronounced innocent; the constable Montmorency was recalled to court; and thus the princes of Lorraine, though they still enjoyed high offices and great power, found a counterpoise to the weight of their influence. To this league, Catherine gave the name of the Triumvirate. In a short time, however, she began to dread the effects of that which she had taken such pains to accomplish; and her endeavours were now directed to weaken the force, and divide the interests of the three great parties. With this view, she tempted the King of Navarre, by the charms of one of her maids of honour, to renounce his claim to the regency as first prince of the blood; and she deceived Coligny, by the protection she afforded to the doctrines and followers of Calvin. This conduct alarmed or disgusted the other branches of the Triumvirate, who, in their turn, used their efforts to weaken and divide the party of the Queen. The King of Navarre, always vacillating and inconstant, was soon drawn over, by the vain promise of receiving the island of Sar dinia as a compensation for his kingdom of Navarre.

In the mean time, the States-general again met, in Meeting of Orleans; but their labours were of no effect the States-General in tranquiliizing the nation. At this assembly, the third estate and the nobility concurred in demanding the reform of the clergy, to whose ignorance and vice they ascribed not only the rapid spread of Calvinism, but all the evils which afflicted the nation. The clergy, however, as might naturally be expected, proclaimed their own innocence, and ascribed the growth of Calvinism, and the distracted state of the country, to the love of innovation. Catherine, always attentive to her own schemes, having at this time professed her desire that the Calvinists should be protected, and even displayed some symptoms of favouring their doctrine, proposed the expedient of a conference between them and the Catholics. The cardinal of Lorraine, filled with vanity, and not doubting that at this conference he should for ever alienate the upper classes of the new doctrine, willingly consented to this scheme. In 1561, Conference of Pains, or conference of Pains, A. D. 1561. therefore, the famous conference of Pains was held, which terminated, as might have been anticipated, in confirming each party in his peculiar tenets, and in increasing the persecuting spirit of the Catholics, and the zeal of the Calvinists. The cardinal of Lorraine, and Theodore Beza, were the principal disputants. Lainez, the second general of the order of the Jesuits, and the principal author of their regulations, was sent by Pope Pius IV. to attend this conference; but the violence and persecuting spirit which he manifested in his harangues, alarmed and displeased Catherine, who, at this time, deemed it her policy to keep her bigotry under the management of her ambition. In order, how-
ever, that her orthodoxy might not be suspected, she agreed to the establishment of a college of Jesuits in France.

In 1562, Catherine, in furtherance of her plan of uniting the Protestants on her side against the Duke of Guise, caused an edict to be issued, by which liberty of conscience was granted to them, on condition that they should hold their religious assemblies only in the suburbs, or in the country, and not in any of the cities or towns of the kingdom. Scarcely was this edict published, before great numbers, whom the fear of persecution had hitherto restrained, now openly professed the reformed religion; the religious assemblies of the Calvinists were crowded; the Catholics were insulted, and they in their turn insulted the Protestants. At this critical juncture, it happened that the Duke of Guise, on his journey to Paris, halted at Viessy, a small town in Champagne, where his attendants insulted a congregation of Protestants, who were assembled at their devotions in a barn. The Protestants being more numerous, and knowing that the law was on their side, repelled the assailants with stones. The Duke, as soon as he learnt what was going on, hastened to the spot, and, in his attempt to quell the dispute, he was wounded in the face. His servants, enraged at this, drew their swords, and killed and wounded above 250 of the Protestants. As soon as the tumult was over, the Duke of Guise severely reprimanded the magistrate of the place, for permitting the assemblies of the Protestants to be held there; and when he pleaded the royal edict in their favour, as his authority and justification, the Duke laying his hand on his sword, angrily replied, "This shall cut the bond of that edict, however strong it may be."

The intelligence of the massacre of Viessy, greatly exaggerated, and the report of the Duke's speech, soon reached the Prince of Condé, who demanded instant satisfaction from the court. Catherine was puzzled how to act; but at length she resolved to promise him the satisfaction he required, well knowing that her promise would be rendered futile by the remonstrances and opposition of the King of Navarre and the Triumvirate. So it happened; they openly refused to obey her commands; and they were strengthened in their refusal, by the arrival of the Duke of Guise at Paris with 12,000 cavalry. Catherine now became seriously alarmed for her own safety, and for the continuance of her power over the King. She therefore made a forcible appeal to the Prince of Condé, exhorting him to rescue his sovereign from captivity, and thus affording him the pretext he wished for to arm his associates. The Triumvirate proclaiming to the nation, that they wished to rescue him from the Calvinists, seized his person, and conducted him, and his indignant mother, who vainly lamented the consequences of her own machinations, first to Melun, and afterwards to the capital.

Such was the beginning of the civil wars, that desolated and weakened France for so long a period of time. The Prince of Condé having consulted with the admiral, put himself at the head of 2000 cavalry, pushed forward, and made himself master of Orleans. Here having established his head-quarters, it became necessary for him to strengthen his cause by every means in his power. His first object was to quiet the suspicions of the Catholics in France as much as possible. With this view, he declared that he had taken up arms, to relieve the King and his mother from captivity. He next despatched messengers into Germany, to solicit the aid of his Protestant brethren; and he gave up Havre to Elizabeth, Queen of England, in order to obtain her assent. The chancellor De l'Hospital made an attempt to prevent the dreadful evils of a civil war; but this failing, both parties prepared for hostilities. The Catholic army was first in a condition to take the field; and after plundering Blois, Tours, and Bourges, it sat down before Rouen. This place was occupied by a garrison under the command of that Montgomery, who had been the innocent cause of the death of Henry II. In consequence of his having been pursued by the implacable resentment of Catherine, he had taken refuge in England, where he had embraced the reformed religion, and from which country he had returned as soon as the civil war commenced. His courage naturally great, and his talents and experience by no means of an ordinary description, were called into full action on this occasion; and the inhabitants, encouraged by his example, refused all offers of capitulation. At last, after a most obstinate defence, the city was taken by assault. Montgomery escaped with a few companions in a boat, but the inhabitants suffered every species of outrage which an enraged soldiery could inflict. In the course of the siege, the King of Navarre received a wound, which soon afterwards caused his death.

The Prince of Condé hitherto had not been able to act offensively; but having now been joined by 12,000 men from Germany, he attempted to surprise Paris; but not succeeding, he retired into Normandy. In his retreat, he was pursued by the Catholic army, which came up to him at Draix. Here, in 1563, the first civil battle took place, and it was fought with the rancorous obstinacy which always fatally distinguishes civil wars. In the beginning of the engagement, nothing could withstand the impetuous charge of the Protestants; and the Constable Montmorency having been wounded, was taken prisoner. But the Duke of Guise, by his calm and circumspect courage, more than compensated for these disasters. The Protestants, in their eagerness of pursuit, had weakened their line; on it the Duke fell suddenly, and with great force. The Prince of Condé, being dismounted and surrounded, was obliged to surrender to the second son of the constable. The command now devolved on Coligny, and it required all his talents, and the animating example of his courage, to rally his troops, and conduct them, before a superior force, towards Orleans.

Although the queen-mother, in consequence of this victory, was fully sensible that the influence of the Princes of Lorraine was become much more formidable than it had ever been before, yet the military talents of the Duke had been so conspicuously displayed in achieving it, that she found herself under the necessity of conferring on him the chief command of the army, with which, indeed, he had been already invested by the tumultuous acclamation of the soldiers. The capture of Orleans was the next object at which the Duke aimed. Coligny, having gone into Normandy in order to receive the supplies which he expected from England, had left in that city his brother D'Andelot with 2000 of his troops, with instructions to defend it to the last extremity. These orders, the Duke, from the tried valor of D'Andelot, had every reason to conclude would be obeyed in their fullest sense; but he was rather urged on than intimidated by this consideration. In less than a month, he had made himself master of the bridge across the Loire, and of the suburbs; and the fate of Orleans seemed at hand, when the duke was assassinated by a gentleman of the name of Poltrot. In his last moments, he exorted Catherine to extinguish the civil war, which was just begun; he lamented the
The command of the army before Orleans was given, on the death of the Duke, to the Marshal Brissac; but Catherine, at the same time, discovering a wish for peace, the terms were soon settled by the constable and the Prince of Condé. By this treaty, the free exercise of their religion was granted to the Protestants, on condition that they laid down their arms, gave up the places which they occupied, and renounced their alliance with England.

A. D. 1564.

In 1564, Catherine having obliged the parliament of Paris to declare the regal authority at an end, though Charles had not yet completed his 14th year, made a progress through France, along with him, under the pretence of ascertaining its state and resources. At Bayonne, they were met by the Queen of Spain, sister to Charles, and by the Duke of Alva. A long and mysterious conference took place, which, it is said, was held at the solicitation of the Pope. Every thing was conducted in the most private manner; but when the Protestants considered the character of the Duke of Alva, and of his master the King of Spain, both avowed and most bitter enemies to their religion, and the duplicity of Catherine, they were filled with alarm and suspicion. Their apprehension of impending danger was further increased, by the conduct of the Catholic magistrates towards them, who, in direct and open violation of the edict which had recently passed, securing them the free exercise of their religion, threw every obstacle in the way of their assemblies, and rather encouraged than restrained the populace in insulting them. In this state of apprehension, they had recourse to the Prince of Condé; but he, either from prudent motives, or because he still hoped to be appointed lieutenant-general of the kingdom, strongly advised them to suffer quietly. This they did for nearly two years, till the prince, perceiving that the court was not sincere in its conduct towards him, and that it was only waiting for a fit opportunity to crush effectually and for ever the Protestants, determined to have again recourse to arms. Catherine had hoped that her measures were so well concerted, and at the same time so secret, that the Protestants would not proceed to open violence, at least till she was fully prepared to resist and overwhelm them. She was therefore surprised and astonished, when she learnt that the ruin which she had plotted against them, was likely to fall on herself and on her party. The king, Catherine, and the ministers, were at this time at Monceau, when she was informed that the Prince of Condé was preparing to march against that place, for the purpose of seizing the person of Charles. She therefore hastily retired with him into Meaux, and afterwards to Paris. On his way from Meaux to the capital, he was surrounded and protected by a body of 6000 Swiss troops. Scarcely had he proceeded two leagues, before the Prince of Condé appeared in sight at the head of 200 cavalry. The Constable Montmorency, upon this, sent the monarch forward by private roads to Paris, under the escort of a body of cavalry, and with the remainder of the troops succeeded in repulsing the Prince. Thus was a second civil war begun.

Condé being thus deceived in his hope of seizing the king, proceeded to St Denis, which he occupied, and thus cut off the supplies of the capital. Upon this, the constable, notwithstanding he was anxious cautiously to avoid a battle, yet being urged by the tumultuous importunities of the Parisians to free them from the inconveniences of a siege, marched forth at the head of nearly 20,000 men. The Protestants, though their numbers did not exceed 5000, by no means declined a battle. For upwards of three hours, they resisted most courageously such superior numbers, till at length they were compelled to give way; but this victory was dearly bought by the Catholics, at the expense of the death of Montmorency, who, even after he was wounded, and at the advanced age of 75, fought with all the ardour of a young man.

Condé was not dismayed by this defeat; but, having collected his dispersed troops, and having received a strong reinforcement of German Protestants, he appeared again in the field, at the head of a formidable army. He even again blocked up the capital, and attempted to possess himself of the suburbs; but being foiled in this, he traversed the greatest part of the kingdom, and at last laid siege to Chartres, a place of much importance. While he was before this city, terms of accommodation were proposed by the court, and accepted by Condé. They were similar to those formerly granted, and produced rather a suspension of hostilities than a renewal of peace.

The character of Charles now began to unfold itself; and it was such as might have been anticipated from the principles in which he had been brought up,—the maxims which his mother had inculcated,—the example which she had set before them,—and the circumstances of the kingdom, both political and religious, in which he had passed his youth. He was a thorough adept in the art of dissimulation, which indeed he carried to such an extent, that though his bigotry and hatred of Protestants were extreme, they concealed even those feelings, when it was necessary to do, for the accomplishment of his wishes or purposes. He was eager after glory; but even this eagerness bore the stamp of his bigotry; for, instead of looking beyond his own kingdom for the acquisition of it, he contented himself with that glory which could be derived from overwhelming the Protestants: and, unlike a man whose love of glory excludes every thing that is mean or dishonourable, he often preferred the gratification of his bigotted and persecuting spirit, to a fair and open competition with the Protestants in the field of battle. On the death of Montmorency, being importuned to bestow the office of constable on his brother Henry, he replied, "I want no person to carry my sword; I will carry it myself:" by these words not only displaying his own character, but intimating that he thought the office of constable conferred too much power on the person who bore it. The treaty which had been concluded, was not likely to be of long duration: in fact, neither party were sincere. The Prince of Condé had acceded to it, because he was unable to satisfy the demands of his German auxiliaries; and the court party, because they always preferred intrigue and dissimulation to open hostility. In less than six months after it was concluded, Catherine laid a plot for seizing the Prince of Condé and Admiral Coligny. They received intelligence of their danger, fled to Rochelle, and summoned their partisans to their assistance. To this place the Protestants resorted in great numbers; among the rest, Jane, Queen of Navarre, with her infant son, afterwards Henry IV. In vain did the Chancellor de l'Hospital endeavour to avert a civil war; his advice and remonstrances were neglected; he was dismissed from his office; and the seals were given to the Bishop of
Orleans, a most bigotted Catholic. The Duke of Anjou, brother to the king, though little more than 16 years of age, was appointed lieutenant-general of the kingdom; and along with him was sent to the army the Marshal Tavannes, a man of great military experience and reputation. In the mean time, the Prince of Condé was not idle. Having received money and ammunition, he marched to Soissons, in order to meet the reinforcements which he expected from Germany.

As it was of the utmost consequence that the prince should be attacked before he was reinforced, the Catholic army rapidly advanced for this purpose, and succeeded in overtaking them on the banks of the Charente; at Jarmes, a small village in the province of Angoumois. The Protestants were surprised, and they were inferior in numbers; yet, for upwards of seven hours, they fought with the utmost steadiness and bravery. The Prince of Condé's arm was in a scarf, in consequence of a wound received in a former action; and just as the battle was beginning, his leg was accidentally broken by the horse of his brother-in-law: notwithstanding all this, he betrayed no symptoms of pain or uneasiness, but, retaining his wonted dignity and presence of mind, he thus addressed those who immediately surrounded him: "Nobility of France,—know that the Prince of Condé, with an arm in a scarf, and a leg broken, fears not to give battle, since you attend him." At last, after the Prince himself, Coligny, D'Andelot, Montgomery, and Rochevoucalt, had vied with each other in displays of skill and valour, the Protestants were compelled to yield. The Prince alone, incapable of flight, covered with wounds, and exhausted with fatigue, was surrounded and taken prisoner, and afterwards killed in cold blood by a captain of the Duke of Anjou's guard.

The Protestants, though defeated, were not dispirited, and the resources of the fertile mind of Coligny were called into immediate and full action on this occasion. He collected the scattered troops, took such measures for their security and protection as he deemed most proper and necessary, and succeeded in reaching Poitiers. Here he was joined by the Queen of Navarre, with such troops as he could collect; and her young son Henry, presented to the army, and received with universal acclamations, was declared general, along with his cousin the young Prince of Condé.

Coligny, who still exercised the actual command and direction of the forces, being strengthened by some German auxiliaries, again took the field, obliged the Duke of Anjou to retreat, and invested Poiitiers. Into this place, the young Duke of Guise, recollecting the glory which his father had acquired by his defence of Metz, had thrown himself, and animated the garrison, by his valour and conduct, to a most resolute defence. In the mean time, the Duke of Anjou advanced with a powerful army; and Coligny thus threatened, and finding that there was no chance of reducing Poiitiers, abandoned the siege. He would have also carefully avoided a battle; but as he was incapable of satisfying the demands of his German auxiliaries, he was under the necessity of fighting while they remained with him, lest on their departure he might be attacked at a still greater disadvantage. Such was the cause which led to the battle of Moncontour. The obstinacy of the combatants was great; but the numbers of the Catholics, and the superior discipline of the Swiss, prevailed. The admiral was wounded in the beginning of the action; but his wound was totally disregarded, and he continued fighting with the utmost gallantry, till he was convinced that his efforts were no longer of any advantage. He then, at the head of only 800 horse, accompanied by the young King of Navarre and the Prince of Condé, reached Parthenay, about six leagues from the field of battle. Such was the rise of the reputation of the second Duke of Guise; for to his obstinate and skilful defence of Poitiers, the disasters of the Protestants may justly be ascribed.

As the Protestants had lost nearly 10,000 men in the battle of Moncontour, the court of France and the Catholics fondly imagined that their power was finally and completely broken; what then was their surprise to learn, that Coligny, undaunted by so signal a defeat, had suddenly appeared in another quarter of the kingdom; had assembled a formidable army, accomplished an incredible march, and was ready to besiege Paris. The state of the finances was such, that the king found it impossible to raise and support an army sufficiently powerful to overcome the persevering and indefatigable Coligny: he was therefore obliged A.D. 1570, notwithstanding his violent animosity against the Protestants, to enter into a negotiation with them at St Germain en Laye. By this treaty, the edicts in their favour were confirmed; a pardon was granted for all their past offences; they were declared capable of all offices, both civil and military; they were restored to all their employments and dignities; and Rochelle, La Charite, Montauban, and Cognac, were ceded to them for two years, as places of refuge, and pledges for their security. The first of these cities kept the sea open for receiving succours from England; the second preserved the passage of the Loire; the third commanded the frontiers of Languedoc; and the fourth opened a passage into Angoumois, where the Protestants possessed greater strength than in any other province.

Both Catherine and her son, being now convinced that the destruction of the Protestants could be effected only by intrigue, resolved to exert all the powers of the Guises on the minds to carry it on in such a manner as might most effectually deceive the proposed victims of it. With this view they pretended to be averse to the measures of the Guises as unfriendly to the Protestants; and even treated them with coolness and indifference. The king proposed to give his sister Margaret in marriage to Henry of Navarre, as a further proof of his change of sentiments, and further security to the Protestants. This proposal was readily accepted; and so deeply laid were the plans of Catherine and her son, that even the Admiral Coligny, notwithstanding a letter which he received, putting him in mind of the faithless characters of them both, was deceived by their specious conduct and professions.

Catherine, having so often been foiled in her attempts to teach the Protestants, both by open and secret measures, was resolved that her present plan should not be frustrated by precipitation: for two years she permitted France to enjoy the blessings of tranquillity; and during the whole of this period, the conduct both of herself and of the king, continued such, as effectually lulled the suspicions of the most timid and apprehensive Protestants. At last having succeeded in persuading the admiral to come to Paris, along with the most considerable men of the Protestant party, in order to assist at the celebration of the marriage of Margaret and Henry, Catherine and the king resolved to hasten the catastrophe.

The marriage was celebrated on the 17th of August.
1572; and, on the 23d of that month, Coligny was wounded by a shot from a window, as he was going to his house. Upon learning this, the king paid him a visit, proposed to send out and punish the assassins, and to all appearance was filled with indignation and sorrow for the accident. Two days after this, on the 24th of August, the massacre of St. Bartholomew took place.

Massacre of St. Bartho-

lonew

A. D. 1572.

The king gave his directions respecting it, he added, with his customary oath, "Since it is to be done, take care that no one escapes to reproach me."

The direction of the massacre was entrusted more especially to the Duke of Guise; and the signal for its commencement was to be given by striking the great bell of the palace. Coligny, regular in his habits, and still weak with his wounds, had retired to rest on the eve of St. Bartholomew very early; but he was roused by the noise of the assassins, who had surrounded his house.

A German, of the name of Besme, entered his chamber; and the admiral, suspicious of his designs, prepared to meet his fate with calm and firm resignation. Scarcely had he uttered the words, "Young man, respect these grey hairs, nor stain them with blood," when the German plunged his sword into his bosom, and afterwards threw the corpse into the court. The Duke of Guise beheld it in silence; but Henry, Count of Angouleme, natural brother of the king, spurned his foot with his horse, exclaiming, "Courage, my friends; we have begun well, let us also finish well."

For five days did the massacre continue. The Catholic citizens, who had been secretly prepared, by their leaders, for such a scene, zealously seconded the execution of the soldiery, and imbibed their hands, without remorse, in the blood of their neighbours, their companions, and even their nearest relations. Among the most illustrious victims, beside Coligny, were the Count de Rochefoucault and Teligni, who had married the daughter of the admiral. The Count de Montgomery, and the Vidame of Chartres, with near a hundred others, who lodged on the south of the Seine, escaped on horseback, half naked; but they were pursued and overtaken by the Duke of Guise, who cut in pieces nearly the whole of them.

The young King of Navarre and the Prince of Condé, exempted from the general destruction, were brought before Charles, and commanded to abjure their religion. The King of Navarre consented; but the Prince hesitating, Charles, in a transport, exclaimed, "Death, massa, or the bastile!" The violence of this threat intimidated the Prince; and, recanting his heresy, he received absolution from the Cardinal of Bourbon.

During the greater part of the massacre, Charles posted himself at one of the windows of his palace, from which he not only saw and encouraged the assassins, by frequently calling out, "Kill, kill!" but even repeatedly fired upon the miserable fugitives.

The same barbarous orders were sent to all the provinces of the kingdom; and they were faithfully obeyed in Lyons, Orleans, Rouen, Bourges, Angers, and Toulouse. In Provence, Dauphine, and some other parts, the Protestants were protected. The Count Visconti Orthes, who commanded in Bayonne, in reply to the order which he received, wrote back to the king, that Bayonne contained loyal citizens and brave soldiers, but that among them he was not able to find one executioner. The Bishop of Lescus, on this occasion, conducted himself in a manner becoming the religion of which he was the minister; for when the commandant of that place communicated to him the orders of the court, he answered, "You must not execute them; those whom you are commanded to destroy are my flock; it is true they have gone astray, but I shall use my endeavours to bring them back to the right fold. The gospel does not say, that the shepherd should spill the blood of his flock; on the contrary, I read in it, that I ought, if necessary, to spill my blood for them."

These instances of humanity were, however, few; and it is supposed that, throughout France, 25,000 Protestants perished, and in Paris alone 10,000.

As a justification of this dreadful and unparalleled massacre, Charles pretended, that the Protestants had formed a conspiracy to seize his person; and that, in his own defence, he had been under the necessity of giving orders for its execution. But the real motive and object were by no means thus concealed; nay, they were even displayed to public notice, by the proceedings of the parliament and the court. The former ordered an annual procession to celebrate the deliverance of the kingdom; and the latter had a medal struck, with a legend, intimating, in express terms, that piety had armed justice on this occasion. Still more unequivocally were the real causes of the massacre of St. Bartholomew displayed by the feelings with which the intelligence of it was received at Rome and in Spain. In both, public rejoicings were held, and solemn thanks were pronounced to God, for the "triumphe of the church militant." Among the Protestants, it excited the most deep and penetrating horror, and no where to a greater degree than in England. Fenelon, the French ambassador at the court of St. James, gives the following striking picture of his first audience after the massacre was known: "A gloomy sorrow sate on every face; silence, as in the dead of night, reigned through all the chambers of the royal apartments; the ladies and the courtiers, clad in deep mourning, were ranged on every side; and as I passed by them, in my approach to the queen, not one bestowed on me a favourable look, or made the least return to my salutations."

The effect of the massacre on the Protestants was directly the reverse of what the king expected; but exactly such as a knowledge of human nature, and of religious zeal and enthusiasm, would have anticipated. Calvinism, instead of being destroyed, became more formidable by despair; and a thirst for revenge, united to an ardent religion of civil and spiritual liberty. A new civil war was kindled. The Protestants assembled in large bodies, and took refuge in the strong places which belonged to their party. In these, now fatally convinced that their only alternative was open rebellion—if rebellion it might be called—or persecution, they resolved to defend themselves to the last extremity. At their head appeared the King of Navarre and the Prince of Condé, both of whom abjured a religion which they had been compelled to profess. Rochelle made a desperate defence against the Duke of Anjou, who lost almost all his army before it. The siege continued eight months, during which time the citizens repelled nine general, and twenty particular attacks, and at length obliged the Duke to grant them an advantageous peace. The town of Sancerre was defended with equal bravery for upwards of seven months; nor did the inhabitants surrender till they had obtained the promise of liberty of conscience. About this time, the Duke of Anjou was elected King of Poland; and the miseries of France daily increasing, Charles embraced the pretence afforded by the elevation of his brother to conclude a treaty with the Protestants, which he did not intend to keep, and to which they never trusted.
In the following year, A.D. 1574, a third party arose in France, which, without paying the least attention to the religious disputes and differences of the other two parties, confined their efforts entirely to politics; they were called the Malcontents. Their avowed object was to reform the political state of the kingdom, by setting limits to the power and influence of the Guises; excluding the queen from the administration of affairs; and banishing from the kingdom all the Italians, whom she had introduced and countenanced. The Duke of Alençon, brother to the king, a man restless, intriguing, and versatile, put himself at the head of this party.

In the midst of this disordered and embarrased state of the kingdom, the health of Charles was rapidly declining. Ever since the massacre of Bartholomew, a deep and suspicious gloom overspread his countenance, and his mind was torn by contending passions. He still hated the Protestants; but he was alarmed at the ambitious views and extensive influence of the families of Montmorency and Guise, while he was deeply affected by the intrigues of his brother the Duke of Alençon, and the King of Navarre. In this state of bodily weakness and mental agitation, he began to suspect that he had been too easily led by the counsels of his mother, into a line of conduct neither conducive to his peace of mind, honourable to his name, nor advantageous to his own interests, or those of his kingdom. This reflection, coming thus late, served only to increase his bodily and mental sufferings. His health declined with great rapidity; each day some new and fatal symptoms manifested themselves; and at last his disorder took a most singular turn. While a slow and internal fever preyed on his strength, the blood oozed even out of the pores of his skin. Catherine was suspected of having administered poison to him; but it is more probable, that his disorder was occasioned by the dissipate life which he had led, and by the excessive violence of his temper. For some time, such was the remaining power of a constitution naturally strong, he struggled against his disorder; but at length, in the 23d year of his age, it overcame him. His last hours were worthy of a better life, and a better character. These he spent in recommending to those around him to preserve their fidelity to the King of Poland, the heir to the throne on his decease; and he obliged all present to take an oath of fidelity to Catherine during the absence of Henry.

Charles was not nowhere devoid of qualities and talents, which, if they had not been counteracted by a most vicious education, might have rendered him a blessing to his subjects. He possessed wit, judgment, activity, and courage; but his disposition was naturally violent; and those who had the care of him in early life, especially the Marshal de Retz, had encouraged, instead of repressed, this violence. From his mother he learnt the whole mystery of the Italian school of politics, and consequently was an adept in dissimulation and intrigue. Indeed, so far did he carry this habit, that he not unfrequently preferred obtaining by deceit, what he might much more easily and certainly have acquired by open and ingenous conduct; and his public life shews, that even the systematic dissimulation which he learnt from his mother, was as frequently prejudicial as advantageous to him. His tutor Amyot had given him a taste for learning, and he cultivated poetry.

Notwithstanding the distractions of this reign, many laws and ordinances, originating in wise and profound views of the public benefit, were passed, chiefly through the labour and patriotic efforts of the Chancellor De l'Hospital. In the midst of the civil wars, this really great man fixed his undivided attention and wishes on the good of his country; and such was the commanding influence of his character, and his activity and zeal, that at a time when law generally is trampeled under foot, he made it be respected and acted upon.

On the death of Charles IX. the king of Poland, who succeeded him under the name of Henry III., hastened to take possession of the throne. Dreading lest the Poles should detain him, he withdrew privately, as if he had been a prisoner making his escape. As he passed through the dominions of the Emperor and the Republic of Venice, he was advised to treat the Protestants with justice, if with gentleness and kindness, and to avoid persecuting them, if he wished to restore tranquility to France; but this advice was given in vain to a man who had been one of the advisers of the massacre, and who, to the utmost depravity of manners, added the external observances of the lowest superstition.

Sarcely was he seated on the throne of France, when he manifested a total unfitness for his situation, even independent of his bigotry and depravity; for he was totally averse to business—occupied and interested only in the most low and trifling pursuits and objects; and utterly devoid even of the manners and dignity of a sovereign.

As the kingdom was still divided by factions, Catherine persuaded Henry to take advantage of this circumstance, and by acting as umpire between them, to restore the royal authority to its pristine dignity and extent; but the king, though not unfit for this line of conduct, in respect to his habits of dissimulation, was totally disqualified for it, on account of his want of vigour, application, and sound understanding; instead therefore of acquiring advantage over both factions, he lost the confidence of both, and taught the partizans of each to regard him with suspicion, and to adhere more closely to their respective leaders.

In the mean time, A.D. 1575, the Duke of Alençon, who, as has already been stated, had put himself at the head of the political party, united with the Protestants, while they were further encouraged and strengthened by the presence of the King of Navarre, and by the arrival of the Prince of Conde at the head of a German army. The king upon this found himself under the necessity of concluding a treaty with them, by which they obtained the public exercise of their religion, except within two leagues of the court; party chambers, composed of an equal number of Protestants and Catholics, were established in all the parliaments of the kingdom; all attainders were reversed, and eight cautionary towns were put into their possession.

But, while Henry by this treaty pacified the Protestants and dissuaded, he excited the greatest disgust and indignation among the Catholics and affording the Duke of Guise the pretext, which he had long sought, of putting himself at the head of a most formidable party, for the express purpose of entirely suppressing the Protestant religion in France. This was the origin of the famous Company of the League, the members of which openly declared, that they would withstand the royal authority in all cases where that authority was at variance with the commands or the interests of the Catholic religion. Henry now saw the error which he had committed in making peace with the Protestants; and as he possessed neither the justice nor the vigour that might have prompted and enabled him to protect the Protestants against the League, while he saw that the members of it had it in their power even to shake the foundations of his
In 1581, hostilities between the two parties commenced, and the King of Navarre signaled himself at the siege of Calais. About the same time, the Duke of Anjou, Henry's brother, secretly retired from France, to put himself at the head of the Dutch, who had risen against Philip II.; but his caprice and perfidy disappointed the hopes which he entertained, and he was obliged to return into France, where he soon afterwards died. This event completely unfolded the real views of the members of the League; for as the King of Navarre, by the death of the Duke of Anjou, was presumptive heir of the crown, they inflamed the people with the dread of an heretic sovereign, and avowed their resolution to support the pretensions of the Cardinal of Bourbon, uncle to the King of Navarre, a zealous Papist, but incapable, from age and weakness, of holding the reins of government. In the proclamations issued by the League, the character of the King of France was not spared; he was held up to his subjects as debauched, —the instrument of unworthy favourites, and especially as the secret friend of the King of Navarre, and the protector of the sectaries of Geneva. The people were led away by these representations, and filled with the most violent bigotry.

In 1581, the Duke of Guise, as the general of the League, took the field; and though his army scarcely exceeded 5000 men, he gained possession of Verdun, but he was repulsed from Metz by the Duke D'Epernon. If Henry had taken advantage of this, he might have re-established his power; but he was no longer capable of any great or arduous enterprise, and he concluded a peace on the most dishonourable terms; agreeing to compel the Protestants to restore the cautionary towns, to annul all the edicts in their favour, and to join the League with all his forces. He thus virtually resigned his sovereign authority into the hands of the Duke of Guise, who nominated a council of 16 citizens for the government of the capital, and intimated to them his wish that they should take measures for de-throning their sovereign, and bestowing the crown on himself. In pursuance of this design, the inhabitants of Paris presented a memorial, in which they required the King to declare openly for the League,—to revive the Council of Trent,—to establish the inquisition, and to extirpate heresy: so low were the power and the firmness of mind of Henry sunk, that he promised to take this memorial into consideration.

In 1588, the Duke of Guise had the audacity, contrary to the express commands of his sovereign, to enter the city of Paris amidst the loud and universal acclamations of the citizens, and demanded an audience of him. To this, however, Henry would not consent; his timid spirit was at length roused; he declared that the death of the Duke of Guise should be the consequence of his foregoing this interview. Catherine now interposed her authority, and even her tears; but in vain. Henry remained inflexible, till at length the Duke, afraid that he had passed even the limits of the king's punitiveness, and sensible of his danger, endeavored to disarm the royal rage by submission. He was permitted to retire; but his soul breathed indignation and revenge, and he instantly prepared for the most decisive and determined measures. Henry, at this juncture, had given orders for 6000 of the troops, on whose fidelity he could place the utmost reliance, to enter Paris: the citizens took the alarm; they were conscious of the punishment which they deserved for their insolent behaviour to their sovereign; they flew to arms; the capital became the scene of the greatest confusion and alarm; the soldiers were surrounded and overcame. Catherine now saw, that if she did not interfere, the life of her son would probably be sacrificed; she therefore entered into a private negotiation with the Duke, while Henry quitted the palace, and effected his escape through the gardens of the Tulleries. It is said that when he was safe, turning back to look at his capital, he declared that he would never enter it again except through a breach in its walls.

From Paris, the king retired to Chartres, whence he appealed to the loyalty and duty of his subjects. His appeals were answered by the manifestations of the Duke of Guise; but, in the midst of these mutual accusations, the efforts and intrigues of Catherine were directed to an accommodation, which she could not expect would be sincere or lasting on either side, but from which she hoped to derive advantages to her own cause. A treaty was accordingly entered into between the King and his rebellious subjects, according to which the Duke of Guise was appointed lieutenant-general of the French armies; the Cardinal of Bourbon was declared first prince of the blood; and the severest penalties were denounced against those who had presumed to leave the ancient and established religion of the country. From these terms, it is evident, that the Duke of Guise had obtained all he could wish, or had taken up arms for. He was confirmed in the chief command of the army, and the King of Navarre was excluded from the throne. Henry was soon made sensible of the ignominious conditions to which, by the advice of his mother, he had consented; and he breathed a expectation to the Duke, while he excluded Catherine from his councils. In this dilemma, he had recourse to a most bold and unexpected measure, which indicated a greater portion of decision and policy than it was supposed he possessed. He assembled the states at Blois; and though the greatest number of those who met were the partisans of the League, he boldly made his appeal to them, dwelling in the most animated and forcible manner on the distress into which he had been brought by the seditions conduct of the house of Lorraine. Had his future conduct corresponded with his behaviour before the states, he probably would have roused the latent loyalty of his subjects; but, on the remonstrances of the Duke of Guise, he softened the most obnoxious passages of his address before it was circulated through the kingdom. Soon after this, having received intelligence that the Duke had held a secret and reasonable correspondence...
In this extremity, Henry at last determined to do that which he ought to have done at the commencement of the troubles; he entered into a confederacy with the Protestants and the King of Navarre. Large bodies of Swiss and German cavalry were enlisted; and the chief nobility and the princes of the blood rallying round their monarch at this critical juncture, he was enabled to assemble an army of 40,000 men. Still, however, the superstitious weakness of his mind broke out; alarmed at the excommunication which the Pope had pronounced against him, he solicited absolution at

“Let us consider,” said the King of Navarre, “and we shall be absolved; but if we be beaten, we shall be excommunicated.” The King of Navarre, also, strongly insisted on the advantages which would ensue from immediately marching to Paris: His advice was followed; and on the last day of July 1589, they invested the capital. The Duke of Mayence was within the walls, with about 4000 regular soldiers; and by means of these, he hoped to inspire and assist the citizens to make a formidable defence. But Henry pushed the siege with uncommon vigour; and as the number of the royalists in Paris was still great, the city must soon have fallen, had not the desperate resolution of one man given a new turn to the affairs of France.

James Clement, a Dominican friar, filled with that bloody spirit of bigotry, which characterised the age, formed the resolution of sacrificing his own life, in order to save the church from the danger to which he conceived it would be exposed, if the King were permitted to live, in consequence of his alliance with the Protestants. This man had succeeded in getting introduced into the King’s presence, under the pretence of important and confidential business, and mortally wounded him, while reading some papers which he had put into his hands. The assassin was instantly put to death by the guards. At Paris he was honoured as a saint and a martyr. The Pope expressed the highest admiration of this act; and all the Catholic clergy defended it as necessary for the safety of the church.

As Henry III. died without children, and the house of Valois was extinct in his person, the throne passed to the house of Bourbon, in the person of Henry IV. This prince was born at Pau, in Bearn, on the 14th of December 1553, of Antony of Bourbon, Duke of Vendome, and Jane of Albert, Queen of Navarre. He was descended in a direct line from Robert of France, Count of Clermont, sixth son of Saint Louis. When his mother was pregnant with him, her father made her promise, that she would sing during her delivery, in order, as he said, that she might not bring forth a gloomy and unfortunate child. She complied with this whim, and, in spite of the pain which she suffered, sung a song in the provincial dialect of Bearn, even at the moment when the child was entering the world. As soon as he was born, his grandfather, taking him into another room, rubbed his lips with garlic and wine, in order, according to his notion, to endow him with a bold and vigorous temperament. In the chateau of Cousages, situated in the middle of rocks, between Begore and Bearn, the young Henry was brought up; and his education was superintended and directed by his grandfather, till the death of the latter, which happened very soon afterwards. He was treated in the most plain and simple manner; his food being confined to brown bread, cheese, and a small quantity of beef; his dress was that of the peasant boys of Bearn, composed entirely of coarse stuff, and made without any ornament. He was accustomed to the most vigorous exercise in all kinds of weather,
and soon became remarkable for the fearless agility with which he clambered over the rocks. Often was he seen during his rambles, with his head and feet uncovered. But the corporeal powers and habits of Henry were not the sole objects of the care and attention of his parents: his mind also was cultivated, but in the same independent and useful manner as his body. His mother, who had avowed herself the protector of the Reformed Religion, invited to her all the most distinguished Protestant priests in that part of France, and the young Henry, who exhibited early indications that he united a solid and clear judgment to a lively and quick apprehension, soon made rapid progress. It is said that one of the books in which he took the most delight; and which therefore may justly be regarded as having materially contributed to form his character, was Plutarch, a French translation of which had recently been made by Amyot.

When Henry ascended the throne of France in 1589, he was in the 35th year of his age; eloquent in counsel, intrepid in action, fertile in resources; and distinguished by wonderful sagacity, the love of glory and his country, uncommon frankness, economy, and talents for business. And he had ample occasion for the exercise of all these qualifications; for his religion prejudiced nearly one half of the royal army against him. The Duke of Mayence, who was appointed to the command of the League, after the death of his brothers, and have assumed the title of king; but he chose rather to confer it on the old Cardinal of Bourbon. Under these circumstances, Henry was under the necessity of signing certain propositions favourable to the Catholics, and promising to listen with attention and impartiality to the arguments of their clergy. Even after these concessions, he found his force far from numerous; and he was obliged to abandon the siege of Paris, and retire into Normandy. The governor of Dieppe opened the gates of that city to him; and the governor of Caen followed his example. He was thus able to preserve a free communication with England, the only power from which he could expect assistance.

The Duke of Mayence, sensible of the importance of reducing these places, advanced into Normandy at the head of 30,000 men; while the army of the king amounted only to 7000. Henry therefore took refuge under the walls of Arques, where he was attacked by the Duke of Mayence, who was encouraged by the exhortations and example of his sovereign. Stood firm, and the Duke found himself under the necessity of retiring from the enterprise. Soon afterwards, the royal army was strengthened by 4000 men from England; and the Swiss cantons, as well as the republic of Venice, acknowledged Henry as king.

Being thus reinforced, he formed the resolution of marching to Paris, in the hope of finding it unguarded; and so rapid and secret was his march, that the Parisians were astonished and intimidated at his appearance; at a time when they thought he was far distant, and by no means in a condition to act on the offensive. He insulted the suburbs; cut in pieces above 1300 of the troops of the League; and if the Duke of Mayence had not arrived, would have made himself master of the capital. In consequence of this, he retired to Tours; and the Duke in Paris solemnly proclaimed the Cardinal of Bourbon King, by the title of Charles X. though at this time he was a prisoner to Henry. The next object of the king was the town of Dreux, before which he sat down with an army of 12,000 men, in the year 1590; but being informed that the army of the League, which was now reinforced by the Prince of Parma, and consisted of 16,000 excellent and experienced troops, was advancing towards him, he raised the siege, and prepared for battle. With this view, he posted his army at Ivry, on the banks of the river Eure. His position here was so strong, that the Duke of Mayence and the secretaries of the League would have avoided an engagement; but the citizens of Paris reproached him with cowardice, and he was further stimulated by the presumptuous and boasting speeches of the Count Egmont. According to him, the cavalry which he commanded were alone able to conquer the whole royal army. The Duke, thus goaded on, gave orders for battle. The conflict was long, and obstinately contested. But the genius of Henry was everywhere present, directing and encouraging his troops, preventing or remedying the mistakes of his officers; while, by his example, he taught the lowest of his followers what he expected from them. "My Lords," said he to them, "if you should lose sight of your colours, rally round this,—pointing to a large white plume which he wore in his hat,—you will always find it in the road to honour. God is with us!" added he emphatically, drawing his sword, and rushing into the thickest of the enemy; but when he perceived their ranks broken, and great havoc committed in the pursuit, he cried out, "Spare my French subjects!" The Duke of Mayence, out of the greatest part of his troops, perished on the field: 2500 of the troops of the League also fell; and the Duke of Mayence himself escaped with difficulty. The Swiss alone remained firm; and after the battle offered their services to Henry.

Had the finances of the king been in a condition such as would have enabled him to increase his forces, this battle, in all probability, would have placed him securely and permanently on the throne. But his want of money was so great, that he could not advance to Paris; and hoping to gain by treaty what he would rather have secured by arms, he entered into a negotiation with his opponents. They, however, were not sincere; but as soon as they had profited by the delay, they broke it off. Two months had now elapsed since the battle of Ivry, and Henry was only beginning his march to Paris. As soon as he arrived before it, he commenced the Blockades and the Cardinal of Bourbon, were still most obstinately averse to Henry, and determined to suffer the greatest ex- centricities rather than deliver a city attacked by a relief. In the solution they were confirmed by the ecclesiastics, who, leaving their cloisters, formed themselves into a regiment, under the command of the Pope's legate. Famine and disease soon began to assail the inhabitants. The Duke of Nemours, who had been appointed governor of the capital, commanded the aged and infirm to leave it. Had Henry refused a passage, it is probable that he must have surrendered; but he rejected the counsels of his officers, who advised him to drive them back with the sword; he even permitted the peasants and his own soldiers to carry provisions secretly to the besieged. "I would rather never possess Paris," said he, "than acquire it by the destruction of its citizens." In the space of the last month of the blockade, famine The Duke of Parma had destroyed above 80,000 of the inhabitants; when the Duke of Parma, by order of the King of Spain, left the Low Countries, and hastened to its relief. On his approach, Henry raised the siege and offered him battle; but the Duke having accomplished the object for which he was sent, refused to fight. Henry in vain endeavoured to force him to it, and even to attack him with advantage, during his retreat; but so great were
FRANCE.

History.

the skill and caution of this celebrated commander, that he retired in the face of his enemy, without so much as putting his army into disorder.

After the retreat of the Duke, Henry again attempted to get possession of Paris; but he was defeated in all his designs, by the vigilance of the citizens, particularly by the fact of Sixteen, by whom it was now governed. Thus foiled in his grand object, he began to consider his situation and prospects in other respects, and he found them by no means favourable. When the Duke of Parma retired, he left 8000 men for the support of the League. Pope Gregory XI. at the request of the King of Spain, not only declared Henry a relapsed heretic, and ordered all Catholics to abandon him, under pain of excommunication; but sent his nephew with troops and money to join the Duke of Savoy, who was already in possession of Provence, and had entered Dauphiné. About the same time, the young Duke of Guise made his escape from the castle of Tours, where he had been confined since the assassination of his father. When Henry was informed of all these threatening circumstances, he coolly observed, "The more enemies we have, the more care we must take, and the more honour there will be in beating them."

Elizabeth, however, was still a steady and useful friend. She had, indeed, on the first prosperous appearance of Henry's affairs, withdrawn her troops; but when she saw him again menaced, she sent, in 1591, 3000 men under Sir John Norris, and afterwards 4000 men under the Earl of Essex. With these supplies, joined to an army of 35,000 men, Henry entered Normandy, and undertook the siege of Rouen. This town was most obstinately defended; but at last, when it was reduced to extremities, the Duke of Parma, by order of Philip, again left his government, and advancing by rapid marches, obliged the king to raise the siege. Henry on this occasion also offered his antagonist battle; but the Duke refused it, and began his retreat. Henry pursued him, but the Duke, by wonderful generalship, in spite of the greatest obstacles and difficulties, a second time made good his retreat into the Netherlands.

The subsequent year, the affairs of the king wore a more promising appearance in Provence, from which his general had driven the Duke of Savoy; and in Languedoc, where the commander of the troops of the League was defeated, with the loss of 2000 men. But it was impossible that the kingdom should long remain in its state of confusion and civil war; even the Catholics began to feel the bad consequences of the relaxation of all government. The faction of Sixteen had hanged the first president of the parliament of Paris, for not condemning to death a man obnoxious to them, but against whom no crime was found. The Duke of Mayence, on the other hand, had caused four of the sixteen to be executed. The Duke of Parma, on the part of the King of Spain, pressed the Duke of Mayence to call an assembly of the states, in order to deliberate on the election of a king; and the Catholics of Henry's party intimated to him, that unless he changed his religion, they would no longer support him. The states were accordingly convoked, and the Duke of Parma, under pretence of supporting their determination, was preparing to enter France with a powerful army, when the death of that general freed Henry from a most formidable enemy. The states, however, met at Paris on the 26th of January 1593; but it was soon evident, that their deliberations and resolutions would be under the influence of the Pope's legate. At the meeting, he produced a bull, requiring the French never to elect Henry, even though he should abjure heresy; while the Duke of Parma, ambassador from Philip II., demanded the throne for the Infanta of Spain, on condition that she married the young Duke of Guise. In order to induce the Duke of Mayence to agree to this demand, he was offered the duchy of Burgundy, with a large sum of money; but the Duke, unwilling to become dependent on his nephew, disputed the powers of the ambassador; and the parliament, roused from its shameful lethargy, passed an arrest in conformity to the Salic law; which, being a fundamental principle of the government, they insisted could not be set aside, even under the pretext of religion.

Henry was now convinced, that even the greatest military successes could not obtain for him the confidence and loyalty of his subjects; he therefore again declared, that he was seriously desirous of being instructed in his religious faith; that he was ready to embrace the truth, as soon as he was convinced of his error; and that the incessant war carried on against him, was the sole cause why he did not employ all his thoughts on that important business. He was therefore appointed to be held between the divines of the two religions, that he might be enabled to take, with more decency, that step which the security of his throne, and the happiness of his subjects, imperiously demanded. These conferences were held at Sureure; and, as the real motive for which they were appointed was well known, the account which Sully gives is not improbable, that the Protestant divines allowed themselves to be foiled, or at least silenced in argument, in order to furnish the king with a better pretext for embracing that religion, which it was so much his interest to profess. While the Catholics contended, that there was no salvation out of the pale of their church, the Protestants acknowledged, that salvation was possible in the Roman church; and thus an easy triumph, and a strong argument, were conceded to the Catholics. This conference, however, not being sufficient to remove the scruples of the king, he afterwards conferred one a two days with some bishops; took his resolution, and performed the ceremony of abjuration at Denne, in presence of a multitude of Parisians—the people flocking to witness the ceremony, though the Pope's legate had prohibited all men from assisting at it, under pain of excommunication. A parish priest in the capital preached nine sermons against the abjuration given to the king; and in various parts of the kingdom the people were roused to rebellion, by the remarks of the clergy on that very act which Henry thought would pacify them. The Protestants behaved differently; they were convinced that the king could never succeed while he professes his religion, and as they knew he would always support them, they preferred his powerful support as a Catholic king, to his weak protection as a Protestant prince.

Though the court of Spain and the Pope in vain endeavoured to allay that satisfaction which was generally diffused over France by the conversion of Henry, yet his event did not immediately produce all the beneficial effects expected from it. The Marquis of Vitré, who, on the death of Henry II., had deserted the king, and had been appointed by the League to the command of Meaux, was the first man of rank who returned to his allegiance. He had often solicited the Duke of Mayence in vain to make peace with the king, as the cause of the war was at an end; and on
Several cities acknowledged him.

The king determined to take advantage of returning prosperity to celebrate his coronation. As Rheims was still in the possession of the enemy, he was crowned at Chartres. Almost immediately afterwards, the provinces of Orleanois and Berri were delivered up by their respective governors to the king; and a singular accident restored the capital to him. The Duke of Mayence having been obliged to leave it, to quell some disturbances in Picardy, had entrusted the command of it to the Count de Brisec. This nobleman seems to have formed the romantic idea of establishing a republic in France; but his designs being received with contempt by the chiefs of the League, he delivered up the capital to Henry. Villars, who had so gallantly defended Rousen, soon afterwards opened the gates of that city, and proclaimed Henry king. The young Duke of Guise also made his peace; and, on the reduction of Laon by the king in person, Amiens, and a great part of Picardy, submitted to him.

In the midst of his successes, his enemies resolved to assail his life. On his return from Picardy to Paris, John Chastel, a scholar of the college of the Jesuits, struck him on the mouth with a knife, as, in the apartment, where he stopped to bless a nobleman that was presented to him. The blow was intended for his throat, but his stooping prevented it touching that dangerous part. Chastel was instantly seized, and delivered over to condign punishment. On his examination, he confessed that he had been prompted to this deed by hearing his preceptors assert, that the murder of kings was lawful, and that as Henry had not yet been absolved by the Pope, he ought still to be regarded and treated as a heretic: hence he inferred that it would be a merit to put him to death. Father Guiscard, on whom were found some writings, which incited the same doctrine, was also executed, and all the Jesuits were banished by a decree of the parliament of Paris.

In 1595, Henry entered the city of Dijon in Burgundy, convinced that his life would be safest while he was in the midst of his troops, and engaged in military affairs. Scarcely, however, had he made himself master of Troyes, before he learnt that the Duke of Mayence, in conjunction with the Spaniards, had crossed the Saone. He immediately resolved to attack them; and conducted himself on this occasion with so much boldness and impetuosity, that, with only 1800 troops, he routed an army of 14,000 men. In Picardy, however, his cause was not so fortunate; the Spanish army invading that province, and reducing several cities of importance, which Henry himself, in compliance with the ambition of his mistress, the fair Gabrielle D'Etrées, who wanted a principality for her son, was employed in a fruitless expedition into Franche Comté. In the subsequent year 1596, the Duke of Guise surprised Marseilles. When Henry was informed of this event, he was so much transported, that he exclaimed, "Then I am at last a king!" The Duke of Mayence, suspecting the sincerity of the Spaniards, from their inactivity and want of zeal, determined to separate himself from them; but he had formed a resolution never to acknowledge Henry, till that monarch had been absolved by the Pope. Henry, being made acquainted with his scruples, secretly suggested to him to retire to Chalons, till his Holiness granted his absolution; and the Duke had scarcely reached that place, when the Roman Pontiff, fully convinced that Henry was firmly established on the throne, absolved him in form. The Duke immediately threw himself at the feet of the sovereign, and vowed a fidelity which he proved to be conscientious, by his future conduct.

Soon after these events, the Archduke Albert, who was there upon the frontier, sent, by the intercession of the Archbishop of Tournai, an army to besiege Calais, which was obliged to surrender, before the king could come to its assistance. This calamity was soon followed by another still more grievous. The city of Amiens was taken by surprise by the Spaniards. Nor were the demands on the king's firmness and mental resources yet exhausted; he was harassed by the complaints of the Protestants, who expected that he would have granted them additional protection and privileges; and the Dukes of Savoy and Morceur, still refused to acknowledge his authority, unless on conditions with which he did not deem it proper to comply. The king at this time labouring under a severe indisposition, felt these misfortunes more keenly; and his difficulties were greatly increased by the exhausted state of his finances. He was therefore under the necessity of assembling his nobles, and making them acquainted with the real state of his affairs; "I have not called you together," said he, "as my predecessors used to do, to oblige you to adopt my measures, or implore your assistance. I have assembled you, to take your advice, to which I will listen with attention and candour, and with a firm resolution to follow it, provided it will benefit the country." But the nobility, though disposed to give their advice, were not in a condition to assist their sovereign in carrying into effect the measures which they recommended; they were exhausted and dispirited. "Give me an army," cried he, "and I will cheerfully sacrifice my life for the state." Troops they could supply him with; but as he complained, bread for these troops could not be procured.

In this critical and embarrassing situation, he had the good sense to appoint the Marquis de Rosny, afterwards the celebrated Duke of Sully, superintendent of the finances; and he soon placed the king in a situation to support the expenses of the war. His financial measures were wise and efficacious, at the same time that they were not burdensome to the people. By means of them, Henry in a short time was at the head of an army of 20,000 men, the best appointed that he had ever commanded. Elizabeth, reinforced this army with 4000 troops; so that in 1597, the king deemed himself sufficiently strong to attempt the recovery of Amiens.

"Let us go," said he, on setting out on this expedition, "and act the King of Navarre; we have acted the King of France long enough." The enterprise was

History.
worthy of the talents of the King; for the Spanish garrison was composed of excellent troops, and commanded by brave and experienced officers. As they were sensible of the great importance of the place, and knew that on that account the Archduke would march to its relief, they made a most obstinate and gallant defence. The Archduke did indeed advance to it, but not being able to force the French lines, though his army was composed of 25,000 excellent troops, he retired, and Amiens surrendered to Henry. The next enterprise of this monarch was against Doullens, which he also hoped to take: But his troops were fatigued; disease and discontent began to prevail among them; the works went slowly on from these causes, and the unfavourable weather; the artillery could not be brought up, in consequence of the badness of the roads; and the vigilance of the Archduke had prepared the city with every thing necessary for its defence. Henry, therefore, had scarcely begun the siege, before he was convinced that it would be wise to abandon it; he accordingly disbanded the greater part of his troops, and leaving his cavalry for the defence of the frontier, returned to Paris. Here he was received with every mark of loyalty and attachment; but his stay could not be long, for Brittany still was in possession of the League; and the Duke of Moreau, of the family of Lorraine, nourished the flames of sedition there. The King, therefore, as soon as the return of spring permitted his troops to march, advanced to Angers. The Duke taken unawares, and deserted by the principal part of the nobility, considered himself as utterly lost, when the lucky thought presented itself of offering his daughter, the heiress of his large estates, to Caesar, the natural son of Henry, by his mistress Gabrielle d'Estrees. The King, glad of an opportunity of gratifying her ambition, readily assented to the proposal, and the nuptials were celebrated with princely magnificence at Angers.

The King of Spain, who had hitherto kept alive the civil war in France, seeing the League destroyed, and being broken down with age and infirmity, felt a sincere desire for peace. As Henry was equally solicitous for it, the mediation of Pope Clement was readily accepted, and at his request a congress was held, by the plenipotentiaries of France and Spain, at Vervins, a town in Picardy. The negotiations were carrying on, Henry beheld himself in what manner he might satisfy the Protestants, without offending the Catholics, or exciting their suspicions. This was no easy task; but he effectually it in a wise and politic manner, by passing the famous edict of Nantes in favour of the Protestants. This edict conformed to them all the rights and privileges which had been granted to them by former princes, and it added a free admission to all employments of trust, profit, and honour; an establishment of chambers of justice, in which the members of the two religions were equal; and liberty to educate their children without restraint in any of the universities. The negotiations at Vervins were attended with considerable difficulties, but these being removed principally by means of the Pope, Henry signed a peace, by which he obtained the restitution of Calais, Ardres, Doulerus, and all the towns of France which Spain had wrested from him, but at the same time gave up his pretensions to Cambrai.

When this peace was concluded in 1598, France stood much in need of repose. The crown was loaded with debts and pensions; the country was uncultivated; the people were poor and miserable; and the nobility, long accustomed to a life of rebellion and plunder, were destitute of all sense of justice, moderation, or loyalty. Henry, therefore, was convinced, that a still more arduous task remained for him than any he had yet undertaken; and that it would be necessary to bring all his powers of mind into action, if he wished to restore happiness to France. He was also convinced, that the measures which it would be necessary to pursue, would meet with violent opposition from all those, whose habits and interests attached them to rapine and disorder; but he was neither intimidated at the greatness, nor perplexed by the intricacy, of the task which he undertook. No man indeed was better qualified for it. His object was single; he suffered no thought or wish to interfere with his desire for the public good; and his talents were of that description, that what he desired ardently and sincerely, he could examine in all its bearings, and ascertain every possible mode by which it could be accomplished. He was aware that he must proceed with caution, and that many must be enticed to do or permit, what, if they were ordered to do, or reasoned with, they would undoubtedly oppose. Among all men of the military profession, he possessed great influence, from his success in war, and his courageous and open disposition; while, to the nobility in general, he was recommended by his magnanimity, gallantry and gaiety. The people loved and reverenced him; they were convinced, that all his actions were directed to their good, and they even gave him credit for aiming at it, when their ignorance or their passions prevented them from perceiving in what manner his measures would promote it. As the more violent and factional had experienced his vigour and promptitude, they were afraid to excite his suspicion, by opposing their schemes. Thus he found himself in such a condition to undertake the mighty and benevolent work of regenerating France, and of curing the wounds which a long civil war had inflicted on her morals, her happiness, and her finances. Still, however, the task was too great for one mind, even of the highest talents, and purest views. Henry, therefore, called to his assistance the Marquis de Losny, whom he created Duke of Sully. This justly celebrated man, in some respects resembled his master; and where he did not resemble him, the difference was, as rendered their dispositions and talents mutually beneficial, instead of antagonistic to each other. Henry was naturally fond of pleasure, and of a volatile temper; hence he required a steady and thoughtful friend, possessed of more coolness and perseverance than himself; this friend he found in Sully. "Attached to his master's person by friendship, and to his interest and the public good by principle, he employed himself with the most indefatigable industry to restore the dignity of the crown without giving umbrage to the nobility, or trespassing on the rights of the people." As all these plans of reform and amelioration depended on the restoration of the finances, Sully first applied his attention to them, and, in a very short time, he exhibited a statement of them so simple, clear, and satisfactory, digesting the whole system into tables, that the King became perfectly master of his own affairs, and was able, by a single glance, to see all the branches of his revenue and expenditure. As it was one of Sully's maxims, that every man employed in collecting the revenue was a citizen lost to the public, and yet maintained by the public, he levied taxes in the shortest and most frugal manner; all the expenses of the government were curtailed: but those which were ne-
necessary, were paid in a punctual and regular manner; and he took especial care, that the King should always have so much in reserve, as could relieve him from the necessity, on any unexpected emergency, of either borrowing, or imposing new taxes. As all these measures were the result of a comprehensive and well-digested system, and as both Henry and his minister were convinced that they were founded in wisdom, and would prove advantageous, they did not permit any deviation or relaxation in their execution. The consequence was, that in the space of five years, all the debts of the crown were paid; the revenue was augmented four millions of livres; and there were four millions of surplus above the regular expenditure in the treasury, while the taxes were much reduced.

Though Sully was convinced that while the finances of a kingdom were embarrassed, the operations of government must be obstructed, and the people so depressed and destitute of confidence in it, as not to co-operate with it in giving due effect to its laws and regulations, and consequently viewed the re-establishment of the finances as a measure first demanding his attention, he by no means regarded it as of the highest importance. His maxim was, that good morals and good laws are reciprocally formed by each other; and as he could not doubt, that good morals constituted the real strength and happiness of a nation, he resolved to secure them by enacting good laws, and by every other method which his penetration and sagacity could devise. He was, indeed, not one of those politicians, who coldly, as well as unwisely, regard the real strength of a nation to consist entirely in its pecuniary resources, or even in its powers to carry on war an extended scale. On the contrary, he was deeply impressed with the conviction, that, even looking to superiority among other nations exclusively, that would be obtained in the most certain and direct manner, by cultivating the moral feelings and knowledge of the people, so as, in the event of a contest which they regarded as just, their moral courage might be in full vigour and activity. He therefore examined carefully the existing laws; the effects which they produced, not merely with respect to the particular crimes which they were intended to prevent, or punish, but also with respect to the general influence they had on the opinions and conduct of the people. He also inquired into the mode in which they were carried into execution; and after having made these inquiries, he warmly co-operated with the king, in repealing such as were hurtful or useless, and in enacting others that were more effective and beneficial, or that the circumstances of society demanded.

In Sully's character, there was a grand and dignified simplicity, which accorded better with the manners, than with the feelings and wishes of Henry; for though that monarch, in his private life, was free from all unnecessary pomp, and enjoyed himself most, when the king was forgotten in the friend or companion, yet his gallantry and love of pleasure, too often led him aside from the path of simplicity, and to prefer ostentation and show. Sully, on the contrary, could not suffer himself to entertain the idea, that luxury was not prejudicial, both to the moral feelings and principles, and to the real strength of a people. He therefore patronised most warmly agricultural pursuits, and seems to have formed the idea, that an agricultural nation possessed within itself all that was necessary for its happiness and security, while its morals were carefully guarded from laxity or corruption. To manufactures he was a decided enemy, considering, that though they might increase the wealth of a people, and its means of enjoyment, yet that wealth must be obtained at the expense of its virtue; and the kinds of enjoyment thus acquired, must be at the expense of that relish for the simple and austere virtues, which alone could render them dignified, and truly independent. But Henry, in this respect, acted differently from the views of his minister; for, contrary to his opinion, he introduced the culture and manufacture of silk; and, before his death, it flourished so extensively, that it brought more money into the kingdom than any of the former staple commodities. He also established, at a great expense, manufactures of linen and tapestry; obtaining the workmen for the first from the United Provinces; and for the last from the Spanish Netherlands. His maxim was to give high wages and great encouragement, in other respects, by making the workmen feel that they were at home, and that they had an interest in the country. In order to facilitate commerce, and promote the convenience of his subjects, he built the Pont Neuf, and cut the canal of Briare, which joins the Seine and Loire.

But Henry was not happy in domestic life. His Queen, Margaret, sister to Charles IX, and Henry III, though domestic, she succeeded in gaining the affections of every other person whom she wished to attach to herself, yet failed to gain those of her husband. She was uncommonly beautiful; possessed of a fine and ardent imagination, and of a delicate and cultivated taste; played on the lute with exquisite skill, and danced with uncommon elegance and grace; but she was violent and ungoverned in her love of pleasure; and mingling the favours of religion with the excesses of dissipation, her time was alternately occupied by enthusiastic devotion, and unrestrained sensuality. Henry, coldly averse to her from the very period of their marriage, was by no means select in his amours, except when some woman of uncommon beauty and accomplishments captivated him. For some considerable time before the peace of Vervins, Gabrielle D'Estrees, whom he had successively created marchioness of Monceaux, and Duchess of Beaufort, had fixed his love. By him she had two sons and a daughter. As Margaret and he were equally anxious for a divorce, Henry entertained the thoughts of raising Gabrielle to the throne, and of legitimating his natural children; but when his intention was made known to the queen and to the Pope, who had already agreed to sanction the divorce, they expressed the most pointed disapprobation of it. Henry, however, was resolute, and probably would have persevered in carrying his intention into effect, had it not been frustrated by the sudden death of his mistress. His amours, grief, at first, was insconsolable; but he could not live without feeling the tender passion. The next object of it was Henriette de Balzac, daughter to Balzac Estragues, by Mary Touchet, the mistress of Charles IX. He immediately created her Marchioness of Verneuil, and even made out a promise of marriage, notwithstanding he was not yet divorced from Margaret. This promise he shewed to Sully, who tore it to pieces. "I believe you are turned a fool," said Henry. "I know it," replied Sully, "and I wish I were the only fool in France." Notwithstanding this daring and virtuous freedom of Sully, Henry was so sensible of his real worth, and sincere attachment to him, that, so far from being offended,
he added to his former employments that of master of the ordinance. At length, in 1599, the sentence of divorce, which he had so long ardently desired, was procured from the court of Rome. But, by this time, Henry's passion was cooled; and reflection taught him, that he had been on the point of staining his character and injuring his people, when he made out the promise to marry his mistress. He therefore resolved to be guided in his second marriage, solely by the consideration of what would most benefit France; and, in order to effect this, and please his subjects, he nominated Mary de Medicis, niece to the grand Duke of Tuscany. But having done this, in compliance with the wishes of his people, and from a conviction that thus he had served their interests, he did not scruple again to deliver himself up to gallantry; and his attachment to the Marchioness of Verneuil was the frequent cause of disagreements between him and his queen.

In the mean time, the intrigues of the court of Spain gave him great uneasiness and alarm. His ancient and invertebrate enemy Philip was indeed no more, but his successor inherited his designs of molesting the throne of Henry, and incited the Duke of Savoy to make war against him. The Duke, however, soon experienced the evil consequences of his proceedings. Bresse, Savoy, and Nice, were immediately subdued by the armies of France; and in a very short time, finding himself not supported, as he expected, by Spain, he implored the mediation of the Pope to extricate him out of a war into which he had thus rashly plunged. In 1601, therefore, a treaty was accordingly formed, on condition that the Duke should cede to Henry the country of Bresse, an extensive territory on the banks of the Rhine, and pay 100,000 crowns to defray the expenses of the war. The Duke, during the war, had engaged in a secret correspondence with the Marshal Biron, who, boasting that he had placed Henry on the throne of France, did not conceive himself sufficiently rewarded for his services, and felt himself humbled, during peace, by his total ignorance even of the lowest branches of learning. These motives and feelings operated to make him wish again for war; and even at the time when he was leading the French armies into the territories of the Duke of Savoy, he was engaged in a correspondence with that prince. This correspondence had not escaped the vigilant attention of the king, who, when at Lyons, reproached him with his seditious designs. The Marshal acknowledged his crime; professed his repentance; protested future fidelity; and thus succeeded in obtaining the forgiveness of his sovereign, who endeavoured still farther to awaken his gratitude, by the grant of a large sum of money; and to keep him out of the way of future guilt, by appointing him ambassador first to the court of England, and afterwards to the Swiss cantons. But the Marshal had no sooner returned from these embassies, than he resumed his ambitious projects; entered into an alliance with the courts of Spain and Turin; and succeeded in drawing over the Duke of Bouillon, and the Count d'Auvergne, natural son to Charles IX. Circumstances seemed to be favourable to the plans of the conspirators; disaffection was widely spread though France, in consequence of Henry's yielding to the influence of his mistress in the improper nomination to ecclesiastical dignities; his neglect of the Protestants; and the numerous imports which it was necessary to lay on, in order to support the state. These complaints, in some respects well-grounded, in other respects without foundation, were listened to and encouraged by the Marshal and his associates; and as the counties of Anjou, Poitou, Saintonge, Auvergne, Guienne and LangUEDoc, were in a state of revolt, they already anticipated the overthrow of the power of Henry. But their hopes and plans were disappointed. They had employed a person of the name of La Fin in their most secret intrigues, who, in a moment of disgust, revealed to Henry the whole of the conspiracy. Henry did not hesitate for the shortest period, in what manner he ought to act; but first went into the seditious provinces, and having overawed the people by his firmness, or brought them back to their duty by his popular manners, and by the recollection of what he had done and suffered for France, he returned to Fontainebleau, determined to bring the principal conspirators to the block, before they were strengthened by the troops of Spain and Savoy. Biron was at this time in his government of Burgundy, strengthening the most important cities in that province, when he received an order from Sully, as master general of the ordnance, to send back the cannon of Burgundy, under pretence of new casting them. No sooner, however, were they transported beyond the government of Biron, than Sully stopped the new ones, with which he had promised to replace them. This first excited the suspicions of Biron, which were confirmed by his learning that La Fin had had a private conference with the king. He now lost all his courage and presence of mind; and though he could not hope for the royal clemency, yet such was his agitation, that he obeyed the summons of Henry, and along with the Count d'Auvergne, repaired to Fontainebleau. Henry still wished, if possible, to save him; and, for this purpose, endeavoured to lead him to a full confession of his guilt, in order that he might justify his clemency; but the Marshal was obstinate; and Henry was at length compelled to give way to the regular proceedings of justice. The proofs being clear and positive, the judges unanimously pronounced the sentence of death. At the place of execution, Biron behaved in a manner by no means becoming his situation, or agreeable to his former conduct; for he was seized by alternate fits of terror and rage, and thus disgraced in his last moments, the character of Intrepid, which he had acquired amidst the dangers of war.

The Duke of Bouillon was yet in arms, and refused to obey the royal summons for his appearance at court. Henry, therefore, determined by his presence to reduce this rebellious subject. Accordingly he directed his course through the provinces of Auvergne and Limousin, and approached where Bouillon was, before that nobleman suspected he had left Fontainebleau. Astonished, therefore, and unprepared for resistance, he ordered the governors of the towns which belonged to him to open their gates, and thus by his apparent sincerity succeeded in disarming the resentment of his sovereign.Scarcey, however, had Henry returned to Paris, when the restless and discontented disposition of the Duke again broke out into acts of sedition; and he found it absolutely necessary to crush him at once and effectually. With a small but well-appointed body of infantry, supported by a train of artillery, under the command of the Duke of Sully, he pressed forward to Sedan; and Bouillon again began to consider his situation dangerous. On Spain he could not rely; the Protestants, with whom he had been a great favourite, were shocked at his disloyalty, and flocked to the standard of the King. He therefore again threw
himself on the royal mercy, and, however unworthy, obtained it.

Henry about this period, experienced a greater share of domestic unhappiness than ever. The temper and habits of the Queen were utterly at variance with his. She was cold, indifferent, and reserved; blindly attached to her Italian favourites, and regardless of the wishes or interests of the King. Such a temperament and conduct were ill calculated to draw him from those amours, to which he was so much addicted. The Queen complained of them, at the very time when she was rendering her own society repelling and disagreeable to her husband. Hence the utmost neces- sity of the palace were disturbed by their mutual and incessant complaints; and Sully, whose good offices were always required on these occasions, often found the utmost difficulty in accommodating these quarrels. The King, wearied out with the arrogance of the Marchioness of Verneuil, sought a new mistress; and was captivated by the wit and sprightliness of the daughter of the constable, Charlotte de Montmorency. So ardent was his passion for this lady, and so completely did it ob- sess his good sense, and pollute the purity and honour of his mind, that he formed the disgraceful resolution of marrying her to the Prince of Condé, that thus he might introduce her into his own family. The Prince, soon after his marriage, discovered that Henry was still attached to his wife, and he desired leave to quit the court. This the King positively refused, and thus confirmed the sus- picious of the Prince, who immediately formed the plan of secretly escaping with his wife beyond the limits of the kingdom. He reached Landrecy in safety, when the King, hearing of his flight, and transported with rage and grief, dispatched the captain of his guards to demand the fugitives from the Archduke; but Albert replied, "that he had never violated the laws of nations on any occasion whatever, and that he could not begin with a prince of the blood royal of France." The Prince and his wife afterwards took up their abode at Brussels; but Henry, instead of being recalled to a sense of duty and respect for his own character by the reply of the Archduke, first ineffectually attempted to carry off the Princess, and then commanded the parliament to pass an act against the Prince, and to condemn him to suffer whatever punishment he might chuse to inflict.

In 1609, a dispute arose concerning the succession to the duchies of Cleves and Juliers, which afforded Henry a pretext for taking up arms, and with the real view of humbling the House of Austria, and circumventing its power in Italy and Germany. On the death of John William, Duke of Cleves, a number of competitors arose; and it appearing to two of them, who were Protestant princes, that the Emperor meant to take possession of the vacant territory, they applied first to the Evangelical Union, a confederation of Protestants, which had been recently formed in Germany, and, as the Emperor was in alliance with the Pope and the King of Spain, afterwards to France. Henry now had a sufficient excuse for breaking openly with the House of Austria; and the refusal of the Archduke to deliver up the Prince and Princess of Condé happening at the same time, private revenge united with public policy in inducing him to receive the Protestant envoy's most favourably for their wishes. He therefore renewed his ancient alliance with the United Provinces, and cultivated the friendship of England; while the Protestant princes of Germany readily united with him in his plan for humbling the House of Austria. Even the Duke of Savoy, induced by the expectation of acquiring the duchy of Milan, if it could be wrested from Austria, agreed to join the confederacy, and to give up Savoy to France; and the Italian states, long worn out by continual warfare, and constantly exposed to irruptions from Germany, Spain, and France, associated in the design, in the hope of possessing undisturbed tranquility and national independence for the future. But it is highly probable, that the design of Henry went much farther, than merely to humble the pride, and reduce the resources and strength of the House of Austria. This might have been the immediate and primary object, but there is good reason to believe, that the plan of a Christian commonwealth, as it is exhibited in Sully's Memoirs, was seriously entertained by Henry.

Concerning this scheme, there have been various ideas. His grand design. To some it appears so romantic, that they cannot believe that it ever actually engaged the attention, or excited the hopes of such men as Henry and Sully; but that a plan was really formed, which was known by the appellation of the grand design, there can be no doubt. According to it, Europe was to be divided into fifteen states, so arranged with respect to situation, and so poised with respect to strength and resources, that there would either be grounds for war, or no probability of any state carrying it on with success. In order to compose these 15 states, the smaller ones were to be united with the greater, and all of them were to be bound together by a well-digested system, such as would render it the interest of all to preserve peace. When we seriously reflect on the romantic nature of this plan, it is scarcely possible to conceive it could have been entertained by Henry or Sully; and we are compelled to believe, that its object was at the same time more practicable, and less disinterested. In fact, if we con- sider the knowledge of mankind, which they both possessed; the experience they had of the difficulties attending even the arrangement of petty concerns, where different states were interested, and the little probability that any object not connected with the interest of France, would rouse their attention, or excite their wishes; we shall be induced to believe, that the aggrandisement of their own country was the final end at which they aimed in their grand design. Or if this conclusion cannot be admitted, there seems no doubt, that the fifteen associated states into which Europe was to be divided, were to be formed solely by means of compulsion; and that the wishes and the interests of those concerned, at least of the inferior states, were not to be consulted.

That the object, whatever it was, which Henry had in view, was to be reached by force of arms, is evident by the great preparations which he made at this time. Besides the armies which his allies promised to bring into the field, he himself had 40,000 men, chiefly veteran and well-disciplined troops. Sully assured him there were forty millions in the treasury; and added, "If you do not increase your army beyond 40,000, I will engage to supply you with money sufficient for the prosecution of the war, without being under the necessity of imposing any new taxes."
though the court of Austria must have entertained suspicions of the real object of so great an armament, and such immense preparations, yet, as the Archduke was not prepared for resistance, he answered in terms of respectful acquiescence. Nothing now retarded his departure, but the coronation of the queen. Sully informs us, the thoughts of this ceremony disquieted him greatly, and that he felt an inward, unaccountable, and obscure dread of some approaching misfortune. It is probable that the greatness of the object which he had in view, might have impressed his manners and countenance with unusual gravity; and that this afterwards was attributed to a presentiment of his fate. At the same time, it must be admitted that the resolution of the narrow escape he had of making, and of the opportunity which a crowd afforded of attacking his life, could hardly fail to arise in his mind; and if it did occur, must have rendered him unquiet and melancholy. Besides, he had often been displeased with the attention and indulgence which the queen displayed to her Italian favourites; and he might apprehend, that, during his absence, they would conduct themselves with more than their usual audacity, and excite the murmurs of the people. Notwithstanding these apprehensions, however, and the dislike which he uniformly expressed, and sincerely felt, for pageantry and ostentation, he agreed that the coronation should take place, and even to be present at it. The ceremony was accordingly performed on Thursday the 15th May 1610, with the utmost magnificence. The next Sunday was fixed for the public entry of the queen, and on the Wednesday following, Henry had resolved to quit Paris, and to put himself at the head of his army. But the termination of the life of this really great king was near at hand. Francis Ravaillac had travelled from Angoulême, his native province, to Paris, in order to procure a livelihood; but being disappointed, and reduced to extreme poverty and wretchedness, he conceived the design of arming his hand against the King of France. Soon after he arrived in the capital, he conducted himself in such a manner as plainly proved him to be a wild and frantic visionary; and this frame of mind must have been rendered still more predominating by the distress under which he laboured. Being a despised Catholic, he regarded Henry, as he was going to assist the Protestants, as still a heretic at heart. Thus maddened by enthusiasm, distress, and bigotry, he watched an opportunity of striking the fatal blow. Henry had proposed to visit the arsenal on the morning of the day after the coronation; but he postponed his intention, in consequence of the indisposition of Sully, till the afternoon, when, finding himself disquieted and restless, he ordered his coach; and, accompanied by the Dukes of Epernon and Montbazon, the Marshals Lavardin and Roquelaire, the Marquises de la Force and Mirabeau, and Du Plessis, Liancourt, his master of the horse, he determined to proceed to the arsenal. The captain of the guards was ordered to the palace to hasten the preparations for the queen’s entry; and the carriage was escorted only by a small number of gentlemen on horseback and the royal footmen. That the king might have a full and unobstructed view of the various ornaments and devices which the citizens had prepared on the occasion, the curtains of the carriage were drawn up on every side. No interruption took place till they came to a narrow street, where the coach was stopped by the accidental meeting of two carts. Most part of the attendants, on this, took a nearer way, and only two footmen were left, one of whom went forward to clear the passage, and the other was accidentally detained behind. Ravaillac, who had been watching a fit opportunity to execute his purpose, instantly stepped forward, mounted the wheel of the carriage, and, as the king turned to read a letter to the Duke of Epernon, he stabbed him over the Duke’s shoulder. Henry had scarcely time to exclaim, “I am wounded!” before a second blow; more fatally directed, pierced his heart; and, breathing only a deep sigh, he sunk down lifeless. The assassin did not attempt to escape, but remained supporting himself on the wheel of the coach, with the bloody knife in his hand, till he was seized. He would immediately have been taken prisoner by the king’s attendants, had not the Duke of Epernon been present. The same nobleman quitted the apprehensions of the multitude, by assuring them that the king was merely wounded, and that they were carrying him to the Louvre, in order to have his wounds dressed. The crowd instantly gave way; and the body being conveyed to the palace, was laid upon a bed; but it is said, that it was soon deserted by most of those who so lately had courted the protection and favour of their sovereign.

The most dreadful tortures were inflicted on Ravaillac: his bones were broken by the arms of the executioner; his flesh was torn by hot pincers; into the wounds thus made, scalding lead and oil were poured; and his mangled body, still quivering with life, was delivered to be torn to pieces by four horses. Even after all these excruciating torments, the vital principle was not destroyed, when the multitude, mad with rage, rushed through the guards, and in an instant the last spark of life was extinguished. In the midst of all his torments, he persisted, that it was entirely his own act, and that he had no accomplice; declaring, that, “impressed with the idea that the armaments of Henry were destined against the Catholic church, he, alone had planned, and was privy to the deed, but that he was now convinced of his guilt, and trusted that his sufferings in this world would atone for it.”

Of the character of Henry, we have already sketched the leading features, as well as pointed out the benefits which, during his reign, he bestowed on his subjects; but the extreme rarity of such an assembly of excellent qualities in a sovereign, will authorize us to recur to the subject. His master virtue undoubtedly was his love for his country; not a cold, abstract, or unenlightened love, but that feeling which constitutes the rarest and highest order of patriotism, which leads him in whose breast it dwells, to be zealous of his country’s rights, to be anxious for its happiness, and most keen and penetrating in examining into the means that will best promote it: while such a person is by no means blind to the imperfections or vices which may prevail in it, but, on the contrary, convinced that they are the enemies of his country’s happiness, his patriotism induces him to acknowledge their existence, and to use his utmost efforts to extirpate them. Under the direction of this warm and exalted patriotism, all the talents of Henry’s powerful and well cultivated mind, were brought into exercise. His chief weakness was undoubtedly his inordinate passion for women, which led him into many irregularities; but this was a blemish rather in his private character, for he never permitted his mistresses to direct his councils, or to influence him in the choice of his servants. It must be confessed, however, that the manners of the nation, at least of the court, were rendered loose and profligate by the example of his libertine conduct: and this loose-
FRANCE.

ness of manners gave rise to other consequences equally fatal; for 4000 French gentlemen are said to have been killed in single combats, chiefly arising from amorous quarrels, during the first eighteen years of his reign. As a general, his talents were undoubtedly high; though his success ought, perhaps, rather to be ascribed to the confidence and affection with which he inspired his officers and soldiers, than to the comprehensive plans on which he conducted his campaigns, or the masterly manœuvre which he put in practice during an engagement. Having been accustomed to the profession of arms from his earliest youth, he not only set an example of labour, sobriety, and courage, but charmed the soldiers by his behaviour and discourse, which entertained them by its sprightliness and vivacity, at the same time that it convinced them that he was really their father and friend. It is scarcely possible to conceive with what eagerness even the common soldiers endeavoured, by their conduct, to deserve his approbation; and it was not because they thus hoped to be substantially rewarded for the least expression of praise from him was hailed with rapture, and acquired inestimable value.

Nor were the soldiers the only class among his subjects who regarded him with the affection of children. The same feeling towards him possessed the breasts of most Frenchmen,—even of those who differed from him with respect to religion, while he was a Protestant, and who suspected his sincerity when he professed himself a Catholic. Of this, they gave such undoubted proofs, as amply to justify the reply of Henry to the Duke of Savoy, when he asked him what the revenue of France amounted to:—"To what I please; for having the hearts of my people, they will grant me whatever I ask; if God sees proper to spare my life, I will take care that France shall be in such a condition, that every peasant in it shall be able to have a fowl in his pot."

The houses of some peasants in Champagne having been pillaged by the soldiery, the King sent for their officers, who happened to be at Paris, and commanded them instantly to repair to Champagne, and restore order, and punish the criminals. "What," said he, "if they ruin my people, who shall support me; how will the finances be supported; who will pay you, sirs? To plunder my people is to plunder me." He was extremely attentive to his officers, and they did not hesitate to consult him respecting all their distresses and difficulties. The Spanish ambassador, expressing his surprise at finding him one day almost besieged by them, the King replied, "If you saw me during a battle, they then gather still more closely round me."

But though he was thus affable, he knew when it was his duty to be firm and resolute. A person of considerable rank and influence asked a favour for his nephew, who had been guilty of murder. His reply was at once dignified, without being harsh. "I am sorry it is not in my power to grant your request. It becomes you to act as the uncle; it becomes me to act as the King. I excuse your request; do you excuse mine?"

To these rare and excellent qualities of the head and heart, Henry added a most possessing physiognomy, which at once commanded respect, and inspired affection and esteem. He was of middle stature; of a fine complexion, a broad forehead, penetrating eyes, an aquiline nose, and brown hair, which however began to turn grey when he was only 33 years old. On this happening, he remarked, that the storm of adversity had early commenced to blow against him.

Such was Henry IV., a sovereign who restored tranquillity to his kingdom; who put an end to the League and to the religious wars which had so long laid it waste, and rendered the feelings and habits of the people barbarous, and averse to regular and industrious pursuits; who introduced order and economy into the administration of the finances, made himself beloved by Frenchmen, and respected by foreigners; and who, in short, reigned gloriously, in spite of so many obstacles, so many disorders, and so many enemies.

By Mary de Medicis he had six children, and eight by his different mistresses, besides those whom he did not acknowledge.

He was in the 58th year of his age, and the 21st of his reign, when he was assassinated.

Louis, the eldest of Henry's three sons, by Mary de Medicis, was only in the ninth year of his age at his father's death, and consequently it was necessary to appoint a regent. A parliament was held, at which the Duke of Etperon, laying his hand on the hilt of his scabbard, said in a threatening tone, "It is still in its scabbard, but shall be drawn, if the queen is not this moment granted a title, which is her right by the order of nature, and the rules of justice." The parliament intimidated, though the decision of this business did not properly belong to them but to the States General, instantly passed an arrêt, appointing Mary de Medicis regent. As she was a woman of a very weak character, she soon became the dupe and instrument of her Italian confidants and favourites. Concini, a native of Florence, Marquis D'Ancre, afterwards Marshal of France, and his wife Eleanora Gallegui, possessed an entire ascendency over her mind, and directed the affairs of the state as they pleased. The Duke of Sully, perceiving that he was no longer capable of benefiting his country by his advice or services, and disgusted with what was going on, indignantly retired from court to his estates, resigning his offices of governor of the Bastile, and superintendent of the finances; but he was persuaded, by his regard to the interests of the Protestants, to enter the field as "Master of the Ordnance, and Governor of the province of Hainaut. Still, however, when his experience or sagacity could be of service to his king or country, he returned to Paris; and, on one of these occasions, the courtiers ridiculing his dress and manners, he said to Louis, "When the King, your father, did me the honour to consult me, he first dismissed all the buffoons and tops of the court."

The political conduct of the French court was now completely changed: instead of pursuing Henry's plan for humbling the House of Austria, the Regent, perceiving that her conduct, especially in giving such countenance and influence to her foreign favourites, created disgust and discontent, and diminished her authority, determined closely to connect herself with that family. Negotiations were opened, and eagerly pursued with the court of Spain; and, while the young King was contracted to the Infanta, the hand of his sister, the Princess Elizabeth, was engaged to the Prince of Asturias. The Protestants immediately took the alarm, auguring that their prosecution would immediately follow this line of foreign politics. The Duke of Rohan, in 1612, seized the strong town of St Jean, the government of which had been promised to him by Henry; alleging, as a pretext for this violent proceeding, that the Duke of Bouillon had removed the mayor, who was attached to his interest, and appointed another entirely at his own devotion. The Queen, timid by nature, and conscious that her power was still weak, immediately endeavoured to pacify,
History

and thus almost justified, the Duke of Rohan, by re-appointing the mayor. The Prince of Condé, who, on learning the death of Henry, had quitted his retreat in Spain, and demanded the regency, as first prince of the blood, had been tempted to forego his claim, by the bribes of a splendid palace and a large sum of money. Still, however, he was discontented, and set himself against the French favourites of the Queen; but being herself entirely guided by the Count of Soissons on the death of the latter, the Marquis D'Ancre found means to attach him to his interest.

In 1613, the Duke of Mantua dying without male issue, the Duke of Savoy, who had long wished to obtain that part of Italy, conceived that this would be a favourable moment for the accomplishment of his object. He therefore attempted to seize Montserrat, an appendage to Mantua, which was also claimed by the brother of the deceased Duke; the latter, finding himself unable to resist his opponent, applied for assistance to the Queen of France, who, in conjunction with Spain and Venice, prepared to support him. The Duke of Savoy, unable to withstand the force which they brought into the field, esteemed himself fortunate in obtaining a truce, by resigning his pretensions to Montserrat and Mantua.

This was the only instance of vigour which the court displayed for upwards of four years. In this interval, it was filled and occupied with the most shameful intrigues which discord and anarchy, their almost unavoidable consequences, spread over the country. The princes of the blood, perceiving that they were neglected, and sensible that their united power was so great as to be equal to that which a feeble court could wield, often raised the standard of revolt, and as frequently laid down their arms, whenever the Regent, conscious of her weakness, offered them what they demanded.

In 1614, the States-general were assembled, in compliance with the wishes of the Italian faction; but nothing of much importance occurred. The clergy, indeed, strongly urged that the decrees of the council of Trent should be published in France, but they were not successful. However, they opposed and rejected, as a rash attempt, a motion made by the third estate, that no temporal or spiritual power had a right to dispose of the kingdom, or to abate the subjects from their oaths of allegiance. An arrêt of Parliament, which declared the independence of the crown to be among the fundamental laws of the kingdom, was afterwards repealed by the assembly.

In 1615, the parliament had the courage to remonstrate, in plain and strong terms, against the dissipation of the treasure which had been left by Henry IV., only two millions of which remained; and on the ruinous and unnecessary expenses which were daily incurred. But an arrêt of council was issued in reply, declaring that the parliament had no right to interfere in affairs of state; and afterwards, the King himself, on the representations and authority of the attorney-general, gave this brief reply: "It is my pleasure, and also the queen's."

The king was now of age, but he still suffered himself to be under the guidance and authority of the queen and her favourites. In the following year, the embarrassments of the court were much increased by the conduct of the Prince of Condé, who had broke out into open rebellion, supported by the Calvinists. An army was assembled; but as there was no vigour nor plan in the councils of the court, the enterprise languished.

and had the Prince persevered, it is probable that Louis would have experienced considerable difficulty in reducing him to subjection; but, after publishing a most violent manifesto, he permitted himself to be duped, laid down his arms, returned to court, and was arrested in the middle of the Louvre in 1616. The imprisonment of the Prince in the Bastille awakened the suspicions and alarms of the Dukes of Vendome, Mayence, Nevers, and Rohan, who, accompanied by a number of the nobility, retired from court, and prepared to take up arms. This was the signal for public discontent to be loudly expressed; and it was farther increased by the dismissal from office of secretary of state, of Villeroi, an old favourite and faithful servant of Henry IV., and by the promotion of the Bishop of Lucon, afterwards the celebrated Cardinal Richelieu, in his stead.

Scurvely had the Bishop taken his seat at the councils of Louis, before he infused talents and vigour into all the departments of the state. Three armies were immediately raised, and took the field, to support the royal authority; the first in Champagne, under the command of the Duke of Guise, the second in the neighbourhood of Montauban, and the third was entrusted to the Count d'Avranches, whom the queen, drawing from the long confinement to which he had been sentenced by Henry, placed at the head of the royal forces in the Isle of France. The Duke of Guise reduced Chateau, Ponceau, and Rethel. The Marshal defeated and took prisoner the second son of the Duke of Nevers; and the Count surprised and dispersed the scattered bodies of the confederates, and shut up in Soissons the Duke of Mayence. This nobleman, son to the celebrated chief of the League in the reign of Henry, must have surrendered, had he not been preserved by an unexpected event.

The Marquis D'Ancre, though deserted and despised by all the nobility of France, had hitherto upheld his power in spite of their efforts to destroy him; but he met with a more dangerous enemy in young Licences, whose fortune was as remarkable as his own. Licences had been placed by the Marquis himself in the person of the young king, into whose second in the midst of which he was, and who, in turn, he soon ingratiated himself by his assiduities, and the ardour with which he entered into his childish amusements. The Marshal thought that no danger of rivalry could be apprehended from one who was occupied by such frivolous pursuits; but this behaviour Licence only pursued, in order to conceal his ambitious views and designs. He soon succeeded in inspiring the king with a jealousy of the authority of the Marquis, and in persuading him to shake off the yoke of his mother. The resolution of Licences to destroy the authority of the Marquis, was strengthened by the refusal of the latter to unite his niece to Licences's brother. From that moment his ambition was whetted by the spirit of revenge. The king listened attentively to the repeated suggestions of Licences, respecting the removal of the Marquis and the Italian favourites of the queen; and was struck with his representations, that his father Henry had regarded with aversion their influence over her mind, and had only been prevented, by his father's entreaties, from sending them back to their own country. Nor was this the only topic on which he dwelt; he insisted on the unpopularity which the king was exposed to, from having imprisoned, at their suggestion, the first prince of the blood, and on the calamities which were impending over France. The restoration of tranquillity and loyalty, both among the nobility

FRANCE.
and the great mass of the people, he said, were easy; and the same means which would render the king respected and beloved by his subjects, would put him in possession of that authority of which he had been so long deprived. Louis listened attentively. At first, the habits of dependence and submission in which he had been brought up, rendered him timid and apprehensive; but afterwards, the love of power, and a sense of his own danger, from the disturbed state of the country, made him anxious to free himself from the influence of the Italians. This resolution he immediately communicated to Licences; and, by his advice, he exacted an oath from the captain of the guard to execute what he should command. Having obtained this oath, he informed him, that the royal orders were, that he should arrest the Marquis. He immediately prepared to obey. By this time, he, as well as his wife and the queen, had intimidation given them of the danger which was hanging over them. The marchioness, intimidated, wished to leave France; but her husband declared, that he never would desert the fortune which had hitherto befriended him. On the morning of the day fixed for his destination, he had gone to the Louvre, surrounded by forty of his favourites or dependants, and was attentively employed in reading a letter, in which the captain of the guard, and a few friends whom he had associated with him in the enterprise, made their appearance. The attendants of D'Ancre, supposing that the king was approaching, gave way; and the captain of the guards advancing, arrested him in the name of the king. Astonished, and suspecting treachery, he laid his hand on his sword. This mark of his resistance was the signal for his destruction: three pistols were instantly fired at him, and he fell lifeless on the ground. As the king was at a window where he could see what was going on, his presence prevented the adherents of D'Ancre from rising in their master's behalf. His son and his wife were immediately arrested. The latter, instead of being tried for her real crimes, though they were sufficiently notorious, was principally accused of sorcery and magic. The judge having demanded what charm she made use of for the purpose of captivating the queen, she replied, nobly and truly, "The descendant which a superior genius has given me is of a weak mind." She was condemned, and suffered the severest torture.

The disgrace of the Queen-mother followed the destruction of her favourites. Licences succeeded to the honours and situations of D'Ancre; the captain of the guards was raised to the rank of marshal; and the Bishop of Lucon was compelled to resign the seals of secretary of state. The submission of the Dukes of Mayence, Vendome, Nevers, and Rohan, were among the first consequences of the fall of the Italian favourites. Licences now turned his attention to the best means of securing the permanency of his high situation, and of emboldening his obscure birth by an illustrious alliance. At first, he aspired to the sister of the Duke of Vendome, the natural daughter of Henry IV.; but he afterwards judged it more prudent to lower his views to the daughter of the Duke of Montaubon, who with pleasure received as his son-in-law the favourite of the king. Still, however, further measures were necessary, to make the nobility and people forget that one favourite had only been destroyed to make room for another. Licences, therefore, who had been created Duke, assembled the states of Rouen in the year 1618, and abolished the most burlesque imposts: he also appeared zealous to procure the freedom of the Prince of Condé, in order to secure the favour of the princes of the blood. By these proceedings, and by the appointment of the Duke of Mayence to the government of Guînone, and the Marshal Ornano to that of Normandy, he succeeded, in a great measure, in accomplishing his object. The government of the Isle of France he reserved to himself, as allowing him, at the same time, to attend to his interest at court.

The Queen-mother, however, was still formidable, even in her exile at Blois: and Licences, consequent[y], could not deem himself perfectly secure. She entered into a plot with the Duke of Epernon, who suddenly quitting Metz at the head of 100 horse, and advancing to Blois, succeeded in rescuing Mary from her captivity, and immediately conveyed her into Angouleme, at the very time when Licences had persuaded Louis to commit her a close prisoner to the castle of Amboise. The king at first was highly enraged, and resolved to recover her mother by force of arms; but Licences, apprehensive that such a proceeding would excite universal disgust and dissatisfaction, had the prudence to oppose this resolution. The Duke of Epernon and Mary, on their part, were sincerely desirous of a reconciliation with the king. In order to effect this, Licences recalled the Bishop of Lucon, and by his influence tranquillity was again established. The Queen-mother was restored to liberty, and in honor of Normandy she received that of Anjou: her adherents were reinstated in their offices; but the Bishop himself, who had been so instrumental in bringing about this wished-for reconciliation, concealing his passion for power till a more favourable opportunity, at present displayed the appearance of an honourable disinterestedness, and refused to accept of any situation.

From the beginning of the reign of Louis, the Protestants had been treated in such a manner, as justly rendered them apprehensive that the privileges granted them by Henry IV. would be infringed. In 1617, the King gave them great offence by an arrest of council, ordering the restitution of the church lands in the district of Bearn, which the Protestants in that province had enjoyed above 60 years. Upon this a meeting was held at Rochelle, and they resolved to erect a republic on the model of the Dutch. About the same period, the people at large began to consider the necessity of new taxes; and the nobility were displeased at the increasing fondness of the king for his favourite the Duke of Licences. The Duke of Mayence retired to his government of Guînone; the Count of Soissons, the Dukes of Vendome, Nevers, Rohan, and Retz, repaired to Angers, where the Queen-mother resided, who had already begun to intrigue again. The Duke of Epernon also declared in her favour; so that she found herself in a condition to assume a lofty and decided tone, and to declare that she never would consent to any future treaty, unless it were guaranteed by the Parliament of France, or by some foreign power. The King's character for indecision and weakness, on this occasion, had induced the Queen-mother and her adherents to pass all bounds of decency: But, to their surprise and terror, he acted with vigour, activity, and firmness: assembling his forces as rapidly as possible, he went into Normandy, where he reduced Caen, and prevented Rohan from joining the rebels. Mary on this took the alarm; and the Bishop of Lucon, in whom she still placed the greatest confidence, prevailed upon her to try the effects of a new negotiation. She deserted her party, and a new treaty, which confirmed the former, was signed. The Bishop of Lucon, on this occa-
sion, threw off the mask which had so long concealed his aspiring and ambitious projects; and entered into an agreement with the Duke of Licences, to bestow the hand of his niece on his nephew, on condition that the Duke should use his influence to raise him to the rank of Cardinal.

Licences having thus succeeded in enlistng on his side the greater and useful talents of Richelieu, turned his thoughts towards the reduction or the conversion of the Protestants; and resolved, for this purpose, immediately to have recourse to arms, while, at the same time, he did not neglect every art of intrigue. The Protestants were apprised of their danger; and scarcely needed the exhortations of the Duke of Rohan, son-in-law to the Duke of Sully, and of his brother the Duke of Soubese, to induce them to resolve on defending their religious liberties at the hazard of their lives. They were, however, deprived of the talents of Du Plessis Mornai, who, in the reign of Henry, had distinguished himself by his ardour in the cause of Calvinism; for he now declared that he could not conscientiously oppose his sovereign, and from this conviction he surrendered the castle of Saumur, which commanded the passage of the Loire. The Dukes of Bouillon and Tremouolle followed his example. The first officer of the royal army, commanded by the king in person, was the reduction of St Jean d'Angeli; the place was gallantly, though ineffectually, defended, for 35 days, by the Duke of Soubese; and, on its surrender, Louis had the magnanimity, as well as the policy, to permit the garrison to depart unmolested. From this place, in 1621, the army proceeded to Montauban, into which the Protestants had thrown a numerous garrison commanded by the Marquis de la Force. The royal army consisted of 25,000 men; but the place was so gallantly defended, that Louis, in spite of their most vigorous efforts, was obliged to abandon the enterprise. Licences died soon after this shameful expedition; and Lesdeguieres, who had already desertaed the Protestants, was, on solemnly renouncing Calvinism, honoured with the Constable's sword; while the Cardinal de Retz succeeded to the presidencyp of the council, in conjunction with the Count of Schomberg. The advice of his new ministers was equally hostile with that of his old to the cause of the Protestants. The Duke of Soubese, after the reduction of St Jean D'Angeli, had put himself at the head of a desperate band, and ravaged the country. On the approach of the royal army, he retired into the isle of Rho, separated from the continent by a small arm of the sea, which was fordable at low water: this arm Louis crossed in the night, and stormed the entrenchments of the Duke, who succeeded in escaping by swimming to the main land. Negreplese was also taken by storm; and all the inhabitants, without regard to age or sex, were put to the sword. This cruelty, however, only filled the breasts of the Protestants with deeper indignation, and roused their courage to a higher degree of enthusiasm. The Duke of Rohan commanded in Montpellier, and prepared to offer a most formidable resistance; but the Prince of Condé marched with a numerous and well-appointed army; but Montpellier was defended as gallantly as Montauban had been, and the prince beheld the flower of his army consumed in ineffectual assaults. Rochelle also, though invested by sea and land, still held out; and Louis, to prevent a second disgrace, listened to the advice of the Constable, and consented to a treaty with the Protestants in 1622. The edict of Nantes was again confirmed; the royal forces were withdrawn from the gates and harbour of Rochelle; and the inhabitants of Montpellier agreed to surrender to their sovereign.

The Cardinal of Retz dying about this time, Cardinal Richelieu, by the influence of the queen, was introduced into the royal councils; secretly had he got a share in the administration, (which in a short time he entirely governed,) before he formed three mighty projects; to subdue the turbulent spirit of the French nobility; to reduce the rebellious Protestants; and to curb the encroachments of the House of Austria. But it was, in the first place, necessary to remove his rivals in the cabinet; the care of the finances, therefore, about which he was most anxious for the prosecution of his designs, was taken from the Duke of Vienneville, and given to Morilloc, a man upon whose subserviency he could completely depend: other changes of a less important nature were also made. His next project, before he entered on the execution of his grand designs, was the expulsion of the Pope from the Valley, in which he accomplished, regardless of the remonstrances of Gregory XV. These, however, were only preliminary steps, or rather intended as indications of the extent of his ambition and of his means; but in order to put his grand designs in execution, it was necessary to preserve peace with England. James I. at this time sat on the throne of that kingdom, and had determined not to bestow the hand of his son Charles, except on a Princess of France or Spain. Richelieu, aware of this, negotiated, in spite of the courts of Rome and Madrid, a treaty of marriage between the Prince of Wales and Henrietta of France, sister of Louis XIII.

He now turned his abilities to the destruction of the Protestants. As the last treaty had been violated in several respects by the court, they were preparing for renewed hostilities, when a new subject of discontent arose. A royal fleet was stationed at L'Orient, to block up the harbour of Rochelle. This the Duke of Soubese offered to attack; and if he failed, the Protestants were to disown his conduct. He succeeded, and his brother the Duke of Rohan immediately displayed the standard of revolt. A sharp but desultory war was carried on, which was terminated for the present, by the mediation of the Queen of England; the edict of Nantes was again confirmed; the harbour of Rochelle freed from blockade; and the King of France agreed that the King of England should guarantee to the Protestants the articles of the peace.

A powerful faction now rose at court against Richelieu. Cabals flourished: not one prince of the blood was sincerely his friend. Gaston, the Duke of Orleans, the King's brother, was his declared enemy. The Queen-mother herself became jealous of him; and even the King was attached to him rather through fear than affection. But the intrigues of the courtiers, thus supported and encouraged, could not escape the vigilance of the Cardinal; he discovered and dissipated all their conspiracies, and at last made himself absolute master of the King and kingdom.

During these cabals, the Protestants, complaining that the terms of the last treaty had not been strictly complied with, displayed a disposition once more to render themselves independent; and in this they were confirmed by the assurances of support which they received from England, where a fleet of 100 sail, and an army of 7000 men, were fitted out for the invasion of France. These preparations, however, were entrusted...
The Protestants were now at the mercy of Richelieu, who had already, by separate treaties, secured the alliance of Spain, and of the United Provinces. The army he assembled was commanded by the King in person, attended by all the principal nobility. The Cardinal himself, aspiring to the reputation of a general, planned the lines of circumvallation, designed the forts, and directed the attack. The citizens of Rochelle, animated by civil and religious zeal, and abundantly provided with military stores, resolved to defend themselves to the last extremity; and their Mayor, Guyton, a man of experience and fortitude, took the command, as neither the Duke of Rohan, nor his brother Soubise, were in the place. The Cardinal, finding it impossible to reduce it so long as the communication by sea remained open, attempted first to shut up the harbour by stakes and by a boom; but these methods being ineffectual, he recollected what Alexander had performed at the siege of Tyre, and erected a mole a mile in length across a gulf, into which the sea rushed with great impetuosity. The inhabitants, before it was completed, saw an English fleet approach; they removed the ramparts on the expectation of relief; but the English Admiral, after throwing in a small supply of corn, either through cowardice or treachery, declined an engagement with the fleet of France, and returned to Portsmouth. The Duke of Buckingham then resolved to resume the command; but while he was hastening the preparations, he was stabbed by Felton. In the mean time the mole was completed, and so strong as to resist all the attacks of the Earl of Lindsay, who succeeded to the command of the English fleet. He was obliged to abandon the enterprise; and as the sails of his squadron vanished from the view of the abandoned and despairing inhabitants, they consented to surrender, after a siege of 12 months. They were deprived of their privileges, and their fortifications were destroyed; but they were permitted to retain possession of their property, and allowed the free exercise of their religion, A.D. 1629. Scarcely had the inhabitants opened their gates, when a tempest arose so violent as to bury in the ocean that mole which had been the cause of their misfortune; so that, if they had held out only a few hours longer, the pride of the Cardinal would have been humbled, and their freedom preserved.

Richelieu, deeply impressed with the advantages that result from quickly following up success, immediately after the fall of Rochelle marched into the other parts of France, where the Protestant party were powerful, or possessed the cautionary towns. He met with the most vigorous resistance in Languedoc from the Duke of Rohan, who, however, when he learnt that England had concluded a peace with France, and thus abandoned the Protestants to their fate, he was forced to negotiation, and obtained very favourable conditions both for himself and his party. The Protestants were permitted to retain their estates, and allowed the free exercise of their religion; all the privileges of the edict of Nantes were also confirmed to them; but they were deprived of their cautionary towns, as dangerous to the state. From this period is justly dated the aggrandizement of the French monarchy, which had suffered considerable diminution by the power that the Protestants had acquired during the civil wars. Indeed, it seems to have been Richelieu's object, not so much to subdue the Protestants, because they were of a different religion from that established in France, as because they had erected themselves into an independant community, and aimed at an entire separation from the monarchy. It was in their political, not in their religious character, that he chiefly regarded them as enemies to his plans of aggrandizing the power of the sovereign; and that this was his view of them, was further apparent in the sequel, when we advert to the assistance which he gave to the Protestants in Germany.

As Richelieu had displayed an extent and variety of talent, during the siege of Rochelle, which he was not previously supposed to possess, the King determined to commit to his superintendence the care of the marine; and for this purpose he persuaded the Duke of Montmorency to resign that situation. This department soon experienced the beneficial effects of the comprehension of the Cardinal's mind, and the activity and vigilance of his management. But he did not confine himself to this or any other particular branch of public business. Indeed, the care of these were only subordinate to his grand and daring designs; for, having subdued the Protestants, he now directed his thoughts to the humbling of the house of Austria. This he perceived could be done most effectually, and at the same time with the least risk to France, by supporting the Protestant party in their efforts against the Hapsburgs, either by wise, or by force, of a less extensive nature, which he did not neglect.

On the death of the Duke of Mantua, the Duke of Nevers claimed the duchy, as the next male heir; but the Emperor thought proper to bestow it on the Duke of Guastalla; and the Duke of Savoy again urged his pretensions to the dependent marquisate of Montserrat. Both were supported by Philip, King of Spain. The Duke of Nevers, in his distress, knew not where to turn for assistance. He had incurred the suspicion of the Cardinal, by uniting with his secret enemies in France. He was the object of dislike to the Queen-mother; but Richelieu possessed so much patriotism, that he abandoned the sense of his own injuries, refused to listen to the complaints of Mary de Medicis, and strongly advised the King to support the Duke against the House of Austria. An army was accordingly formed: Louis placed himself at their head. The Alps were passed; the narrow pass of Susa penetrated; and the Duke of Savoy, alarmed, and unequal to the combat, was under the necessity of deserting his allies, and of uniting his troops with those of France. Casal was at that time besieged by the Spaniards; and when Louis first entered Italy, he meant to have advanced with his whole army to its relief; but, upon learning that the
Duke of Rohan had again roused the Protestants in several provinces, he himself returned with most of his troops, leaving 3000 chosen soldiers for the protection of Casal. The Protestants were soon reduced. In the mean time, the Duke of Savoy, violating his engagements, had joined the Spaniards in the siege of Casal; upon which the Cardinal, lately appointed lieutenant-general, and thus possessed of all military and civil power, prepared to reduce him to submission. In a short time, his troops approached Turin; but while the Duke was preparing for the defence of his capital, Richelieu suddenly changed his direction, marched against Pignerol, an important fortress, which opened a direct passage from Dauphiné to Italy, and took it in 12 days. Louis now joined the army; and, in a short time, reduced the whole of Savoy; which so afflicted the Duke, that it caused his death. This circumstance facilitated the progress of the French; but their career was stopt by a pestilential disorder, that carried off great numbers, and embittered the bodies and minds of most of the survivors. Notwithstanding this calamity, they were ordered to proceed to the relief of Casal, when the treaty of Ratisbon was concluded, which established the Duke of Nevers in the peaceable possession of the duchy of Mantua, and the marquisate of Montserrard.

The designs of the Cardinal against the House of Austria were now ripe for execution. The Emperor and the Protestant princes of Germany were at war: the famous Gustavus Adolphus of Sweden embraced their cause; and Richelieu, regarding this as an excellent opportunity of humbling Austria, agreed to pay Gustavus an annual subsidy of 1,200,000 livres; in consideration of which, the King of Sweden was to maintain in Germany an army of 30,000 men; to observe a strict neutrality towards the Duke of Bavaria, and all the Princes of the Catholic League, provided they did not join the Emperor; and to respect the rights of the Roman Catholic church, wherever he should find it established. Thus Richelieu avoided giving alarm or offence to the Catholics, while he furnished the princes of that persuasion with a sufficient reason for not joining the Emperor, since thus they would be exposed to the hostility of Sweden.

While the war was carrying on in Germany, the Cardinal was employed in France in erasing the conspiracies which were formed against him, at the instigation of the Duke of Orleans and the Queen-mother. His vigilance and activity were so great, that his enemies had no chance against him. Mary de Medicis was banished the kingdom; her son Gaston was obliged to beg his life; the Marshals Morillac and Montmorency were brought to the block; and the most arbitrary sentences were daily passed, in a court erected for the trial of his enemies.

Hitherto France had not engaged in open hostilities with Austria, though, if she had, it is probable the design of Richelieu, of humbling that power, would have been more successful than it proved to be; but jealous of Gustavus, or the necessity of keeping a large force in France to awe the discontented, prevented him from acting in an open and decided manner, till the death of the Swedish monarch rendered his efforts unavailing. It is also known that Oxenstein, the minister of Gustavus, was unwilling at first to give the French any footing in Germany. After the unfortunate battle of Nordlingen, however, Oxenstein put Louis in possession of Philippsburg and Alsace, on condition that France should take an active part in the war against the Emperor. Richelieu also concluded an alliance with the United Provinces, in the hope of gaining part of the Low Countries; and he denounced war against Spain. A treaty was at the same time entered into with the Duke of Savoy, in order to strengthen the French interest in Italy.

In a short time, the activity of Richelieu had prepared five armies for active service. The first and largest was sent into the Low Countries, under the command of the Marshals de Chatillon and Brege; the second, under the command of the Duke de la Force, entered Lorraine; the third, under the Marshal de Crequi, entered Milan; the fourth was led into the Valteline by the Duke of Rohan; and the fifth, under the Duke of Saxe Weimar, acted on the Rhine. But these immense armies performed scarcely any thing corresponding to their magnitude, or to the hopes and designs of Richelieu: indeed, they were too great for the finances of France to support. The Cardinal's household alone, which was more splendid than the King's, swallowed up four millions a year. There was no resource but in the wretched expedient of money-cedicts; and these were accumulated so rapidly, and to such a degree, that at one sitting, the parliament were obliged to register 42 of them, without examining, or even reading them. The consequences were such as might be anticipated: the armies in Flanders and Germany moulder'd away for want of provisions. The first campaign was everywhere unsuccessful, except in the Valteline, where the Duke of Rohan maintained himself with a few troops, against the Germans and Spaniards, while the Marshal de Crequi, though assisted by the Dukes of Savoy and Parma, could make no progress in Italy. Richelieu, in order to raise so many armies, was obliged to expose France, on the side of Picardy, to the incursions of the allies. The Spanish army commanded by Prince Thomas of Savoy and the celebrated Piccolomini, entered this province—passed the Somme—made themselves masters of Corbie—and spread terror into the capital. Richelieu, under these calamities, remained cool and unshaken, and put forth all his vigour and activity. His own guards were dismissed; the horses and domestics of the wealthy, and the personal services of the poor, were put in requisition; and, in a short time, 50,000 men were assembled for the defence of Paris. The command of these was divided between the Duke of Orleans and the Count de Soissons, who compelled the enemy to repass the Somme, and retook Corbie. In the mean time, the Spaniards ravaged Burgundy, and invaded Guienne, but they reaped no advantage from these successes.

Still, however, France had suffered considerably by the war in which she had engaged; and as Richelieu was known to be the adviser of it, his unpopularity increased. The Duke of Orleans and the Count de Soissons, as soon as they had freed their country from the Spaniards, formed a plot to assassinate him in the King's apartment; and the blow would have been struck, had not the resolution of the Duke forsook him at the very moment when the conspirators expected the signal for the assassination. Scarcely, however, had the Cardinal thus narrowly escaped, when he was exposed to danger from a quarter where he least dreaded it. Father Capin, a Jesuit, confessor to the King, employed the influence and opportunities which his character gave him, to exasperate the mind of Louis, by representing the Cardinal as the oppressor of the Queen-mother, the ty-
France.

During the 17th century, the support of heretics: but this scheme was soon discovered, and ended in the banishment of the Count D'Harcourt. The war still continued, notwithstanding the Pope endeavoured to bring about a reconciliation. The Duke of Rohan, not being properly supported, lost the Valence. On the other hand, the Count D'Harcourt recovered the islands of St Margaret and St Honorat, on the coast of Provence, which had been taken by the Spaniards in 1655; the Duke of Valette reduced several forts, which the Spaniards had seized in Guienne; Marshal Schomberg raised the siege of Luquet, and defeated Serbillon, the Spanish general; Cardinal de La Valette reduced Capelle again under the dominion of France; the Marshal de Chatillon obtained possession of Damvilliers in Luxembourg; and the Duke of Longueville successfully advanced in Franche Comté. The Marshal Crequi, aided by the Duke of Savoy, defeated the Spaniards in Italy, under the command of the Duke of Modena; while Breda was obliged to surrender to the Prince of Orange.

In 1637, Ferdinand II. died, and was succeeded in the imperial throne by Ferdinand III. who pursued the same line of politics as his father: hostilities therefore were continued. In the following year, the Duke of Saxe-Weimar, supplied from the treasures of France, took the field again; but he was surprised and routed in the siege of Rheinfeld, where the Duke of Rohan, who served as a volunteer, from a friendship to the Duke of Saxe-Weimar, was mortally wounded. The latter, impatient to wipe off the disgrace of his defeat, collected all his force, and exerted all his talents and skill; and soon conquered in his turn. General de Savelli, and the famous John de Wert, who led the Imperialists, were taken prisoners; and the towns of Rheinfeld and Fribourg, the capital of the Brigswag, were reduced. The siege of Brisac was afterwards undertaken with the greatest confidence of success; during which, the Duke of Lorraine, and the Imperial General Goentz, attempted in vain to check the success of the Duke of Saxe-Weimar; and Brisac was forced to surrender, after it had been reduced to such an extremity that the governor was under the necessity of setting a guard on the burial-places, lest the inhabitants should dig up and devour the dead.

As soon as Richelieu heard of the reduction of Brisac, he immediately formed the scheme of annexing it to France; and accordingly made the proposal to the Duke of Saxe-Weimar. But this general would not part with his conquest: "To part with my conquest," was his reply, "would be to sacrifice my honour: ask a virgin to give up her chastity!" In 1639, the Duke died, not without suspicion that his death had been hastened by the Cardinal, who certainly, as soon as it happened, succeeded in procuring from his successor, not only Brisac, but Fribourg also. Thus was the King of France, by the abilities and intrigues of his minister, rendered sovereign of almost all Alsace, and a great part of the Brigswag.

To retaliate on the Spaniards for their invasion of Picardy, the Prince of Condé was ordered to lay siege to Fenterebin; but he was defeated by the Admiral of Castle, and with the remainder of his army, escaped with difficulty to his ships.

In 1641, the Emperor, though he pretended to be desirous of peace, convoked a diet at Ratisbon; for the purpose of concerted measures for carrying on the war. Upon this the Swedish general Bannier, having joined the French army at Erfurt, formed the design of dis-
command of the French army. The proceedings against the conspirators were carried on at Lyons, under the eyes of the minister. Additional proof was necessary to condemn them; the Duke of Orleans was mean and base enough to furnish it, in order to save his own life. The Duke of Bouillon purchased his pardon, by giving up the principalities of Sedan; but Cinq Mars and De Thou were condemned to death, and executed in 1642. Almost immediately after the execution, the Cardinal having received intelligence of the fall of Perpignan, wrote to the king, "Sire, your enemies are dead, and your troops are in Perpignan." It is said that Louis looking on his watch, about the time when Cinq Mars was to suffer, said, "Within an hour, the great man will pass his time very disagreeably." Richelieu having thus triumphed over his enemies, at the very moment when he was himself approaching the grave, returned to Paris; and as he was obliged to be carried in a litter, a breach was made in the walls of that city to allow it to enter. He survived a very few days. On his death-bed, he protested to Louis, that his counsels had ever been directed to the honour of the crown, and the welfare of the kingdom. The character of the statesman must have sufficiently appeared from his actions. His plans were undoubtedly comprehensible and profound, and in the execution of them he displayed wonderful vigour; but he was stained with the vices of ambition, hypocrisy, cruelty, pride, and avarice. The Emperor Peter the Great of Russia, however, considered him as such a complete statesman, that on his visit to France in 1717, he is said, on viewing the monument of Richelieu, in the church of the Sorbonne, to have exclaimed, "Oh, great man, if you had been alive now, I would have cheerfully given you the half of my empire, I would have taught you how to govern the other half!" Mary de Medicis died soon afterwards in exile and poverty at Cologne.

Some time before his death, Richelieu had obtained a cardinal's hat for Mazarin, and had introduced him into the king's council. It was therefore supposed that he would succeed his patron as prime minister; but Louis resolved to govern himself. The servants of the crown were retained in their situations; and the only change which marked the death of the Cardinal, was the recalling from banishment, and releasing from confinement, the principal objects of the Cardinal's resentment and jealousy. The war was prosecuted with diligence and vigour; though the Swedes, who were at first doubtful of the politics of Louis after the death of the Cardinal, had begun to think of concluding a separate treaty with the Emperor. Mazarin was not, indeed, possessed of the situation, or the influence of the Cardinal; but he had sufficient power over the King to persuade him (to what indeed he was by no means indisposed) to pursue the line of politics marked out by that statesman. All the operations of war were concerted with the same judgment as formerly: supplies of every kind were furnished with equal punctuality. In Germany, Guise, in conjunction with the Swedes, triumphed over the Imperialists; while in Piedmont, Lorraine, Roussillon, and Catalonia, Schomberg, L'Hospital, and two other French generals, were equally successful. Louis, in the midst of these successes, was fast approaching his latter end; and, as the tender years of his son would expose the kingdom to dissensions, unless a wise and vigorous regency were appointed, this subject occupied his whole attention during the remainder of his days. His queen, Anne of Austria, never partook of his confidence; and the Duke of Orleans had discovered himself totally unfit for the high office, by his want of steadiness and vigour of mind; and unworthy of it by his seditious intrigues. He therefore resolved to distribute into different hands the power that he bequeathed, in order to preserve the tranquility of the kingdom during the minority of his successor. The case of the children was entrusted to the Queen, who had also the nominal character of regent; the Duke of Orleans was appointed head of the council, and lieutenant-general of the kingdom. But these appointments were counterbalanced by others, from which Louis hoped that neither the Queen nor his brother would be able to create intrigues, or to weaken the kingdom by the incapacity or folly of their government. In case of the death of the Duke, the Prince of Condé was to fill his situation; and, after him, the Cardinal Mazarin; and it was, in fact, on the last, that Louis, by his arrangements, devoted the real management of the kingdom during the minority of his son. As a farther guard against the Duke of Orleans, the King directed that all affairs which came before the council should be decided by a majority of votes. The Queen and the Duke swore solemnly to preserve inviolate the deed which they had subscribed; and Louis, to render it still more authentic, commanded it to be registered in parliament. After these arrangements were completed, Louis lived but a very short time, expiring in the 42d year of his age, and on the very day of his death, that he had completed the 33d of his reign. This savor. A. D. 1643.

The reign of Louis XIII. was only 41 years of age when his father died. The prospects of France during his minority were by no means of a satisfactory nature; the internal state of the country exhibited discontent and exasperation, created by the measures of Cardinal Richelieu. The War which he had commenced with the house of Austria still continued. The Emperor Ferdinand III. less formidable than his father, struggled against the forces of Sweden and France, even though the forces of the empire, in many cases, resisted his will and his plans. Philip IV. of Spain had lost Roussillon, Catalonia, and Portugal; but he still continued the struggle against the Portuguese, the Dutch, and the French. England, though involved in civil war, was already beginning to exercise that energy which these troubles had created or brought into action, and threatened to become more formidable than ever.

The will of Louis XIII. which has been noticed, his will was violated almost immediately after his death; his widow being invested by an act of the parliament of Paris with continued powers. She immediately gave herself entirely up to the direction and influence of Cardinal Mazarine, who was of a subtle and insinuating character. The court of Spain, imagining that the minority of The Sp. Louis afforded them an excellent opportunity of invad- ing France, marched an army from the Low Countries into Champagne, besieged Rocroy, and spread alarm on every side; but they were mistaken, and unexpectedly were opposed by a general who, at this period, commenced that glorious career which has exalted him to the highest pitch of military fame. Previous to the death of Louis XIII. Louis of Bourbon, Duke of
France.

Enghiem, afterwards honoured with the title of the great Condé, had received the command of the French forces on the frontiers of Flanders. When the Spaniards invaded Champagne, he was scarcely twenty-one years of age; but his want of experience was amply compensated by his genius. His orders were not to risk a battle; yet, on receiving intelligence of the siege of Rocroi, he resolved to attack the besiegers. Hitherto the Spanish infantry had been deemed invincible, but in this battle, the courage of the French, directed by the talents of their young general, deprived them of that character: They were broken by his impetuous charge; the Count of Fuentes, who commanded the army, perished on the field; 9000 were killed, 20 pieces of cannon taken, Rocroi was saved, and the character of the Duke of Enghiem stamped as a great general. When he heard of the death of the Spanish general, he exclaimed, "I could wish to have died like him, had I not been victorious!" Thionville, which had long been the object of Richelieu's ambition and intrigues, but from the reduction of which, by force of arms, he had been deterred by its strength, next fell before the Duke. After this he passed the Rhine, and advanced to avenge the death of Guibrant, who had fallen at the siege of Rotui. On the death of this general, divisions and dissensions took place, of which the Imperialists took advantage, and gained the battle of Dutlingen, as well as the other inferior engagements in Swabia. Fribourg also was reduced by them. The Imperialists, after the reduction of this place, had formed an entrenched camp under its walls, on hearing of the approach of the French; but the Duke was not intimidated by their formidable position, nor their superior numbers; he attacked them in their camp, and, after a battle which lasted three days, he defeated them. Phillipsburgh and Mentz were the fruits of this victory; while General Merci retreated in such good order, as to prove that, at the time of Fribourg, he had only yielded to a general of the first rate talents. In Flanders, during the years 1645, 1646, the Duke of Orleans reduced Gravelines, Mardyke, and Courtray; but the French were not so successful in Catalonia, where Philip IV, defeated the Marshal de la Motte, and took Lerida and Balaguer. In Bohemia, the Swedish general Tortensen had gained a great victory: to improve the advantages of which, Marshal Turenne was ordered to advance with the imperial army; but he committed an error in separating himself from his allies, and thus exposed himself to defeat. At first, indeed, he was successful; he crossed the Rhine at Brisac, and, advancing towards the sources of the Danube, routed the Imperialists. He next attempted to relieve Fribourg, which was invested by the Bavarian army, under the command of a brother of General Merci, but he was defeated. As soon as Cardinal Mazarine learned this, he ordered the Duke of Enghiem to join Turenne with a reinforcement; and the two generals attacked the Count de Merci near Fribourg with such impetuosity, that he was obliged to retire with the loss of 3000 men. This battle, which lasted seven hours, was immediately followed by another, in which the Bavarians at first were successful, but the Duke rallied his troops, and drove the enemy three times from their entrenchments, which they as often regained, till at last Merci, having lost nearly one-half of his army, resolved to retreat. This he effected in good order, notwithstanding all the attempts of the French to harass him, leaving behind all their artillery and baggage. The consequences of this victory, were the reduction of all the towns situa-

ded between the Rhine and the Moselle, from Mentz to Landau.

After this, Turenne established his winter quarters at Marendah, his troops being dispersed in the neighbouring villages. As soon as General Merci learned this, he marched rapidly against him, and gained a partial victory. The Duke of Enghiem was again sent by the Cardinal to reinforce Turenne; and the two generals resolved to bring the Bavarians to a general action. With this view, Turenne, whose diary it was to command, advanced at the head of his cavalry; but the position of the enemy was so strong, that it was not deemed safe to attack them. As soon, however, as the command fell to the Duke, he resolved to march to the Danube, and had got as far as Nordlingen when the Bavarians came up with him. He immediately arranged his army in order of battle, on the very same plain where the Swedes had suffered a defeat soon after the death of Gustavus. The Bavarians were drawn up on an eminence of easy ascent. The attack was begun by the French, who at first gave way, and suffered a great loss; nor could their utmost efforts turn the tide of battle, till De Merci was slain at the head of his conquering troops. Even after his death, the Duke would not have been able to have preserved his troops from destruction, had not Turenne attacked the right wing of the enemy, when a terrible conflict ensued, in which the Battle of Nordlingen was decided. But the French were ready to give way when the Duke came up; and the Bavarians were obliged to retire, leaving behind them their cannon. Turenne now charged them in flank, and their route was complete. This obstinate and well-contested battle produced few favourable consequences to the victors; for though Nordlingen and some other places were reduced, they were soon recovered by the Bavarians, on their receiving a strong reinforcement. The Duke of Enghiem returned to Paris; and Marshal Turenne had the honour of closing the campaign by re-establishing the Elector of Treves in his dominions.

In 1647, the Duke of Enghiem succeeded to the title of Prince of Condé, by the death of his father. At this time, he seems to have excited the jealousy of Mazarine; for he was sent, with an inferior army, very ill equipped, into Catalonia, to effect the reduction of Lerida. The preceding year this place had been besieged by Count D'Harcourt, viceroy of Catalonia; who had suffered himself to be surprised by the Spanish general, in a manner that incurred the displeasure of Mazarine, and induced him to resign his command. The Prince of Condé, on his arrival, found the lines of the Count D'Harcourt so little damaged, that he easily repaired them, and the trenches were opened with a flourish of violins. The city was defended by the governor with very great skill and courage: he harassed the besiegers with continual sallies, and disputed every inch of ground. In the mean time, the French found unexpected difficulties in forming their mines, by the intervention of a rock: the troops were diminished by fatigue; the season was unfavourable for labour, and prejudicial to health, on account of its extreme heat; the Spanish army advanced to the relief of the place, and the Prince of Condé was obliged to raise the siege.

Hitherto the negotiations at Munster and Osnaburgh had varied according to the fortune of war; but the French and Swedes being now decisively victorious, the Emperor, deserted by his allies, was obliged to receive the law from these powers; and consented to purchase peace, by ceding to France the bishoprics of Metz,
Toul, and Verdun, and giving up his pretensions to Pigemal, Brisac, and Alsace. This was the memorable peace of Westphalia, signed at Munster, on the 24th day of October 1648, which, till the French Revolution, was considered as a fundamental law of the empire, and the basis of all subsequent treaties.

France, however, was still at war with the Spanish branch of the House of Austria; and as the United Provinces, jealous of the former power, had concluded a separate treaty with Philip in 1647, the Cardinal found it necessary to exert all his talents at this crisis, especially as his influence was now seriously threatened by intestine disorders.

In 1648, the Prince of Condé resumed the command in Flanders, where he reduced Ypres. He was opposed by the Archduke Leopold, who, to balance this acquisition, took Courtray and Furnes, and advanced to the siege of Lens. This place the prince resolved to relieve if possible, but he had the mortification of beholding it surrender. Still he was determined to engage the enemy; immediately before the battle, he addressed his soldiers in a few but GRAPHIC words:—"Remember, my friends, Rocroy, Fribourg, and Nordlingen." The Spaniards, though superior, were defeated; 5000 were killed; 2000 made prisoners; and the Archduke himself escaped with difficulty.

The civil war in France now calls for our attention. The overthrow of Mazarine was the object of it; he was objectionable to the French on many accounts; in the first place he was a foreigner, and an Italian; in the next place, though he had not the pomp and haughtiness of Richelieu, his fortune, his power, and the necessities of the nation, furnished matter of complaint and discontent. The finances, which had been placed on such an excellent footing by the Duke of Sully, who had, moreover, rendered their collection and management so very simple and easy, that moderate talents and attention, joined to economy, might have kept them so, were in a very dilapidated state. Seventy-five millions, the amount of the revenue, were not sufficient for the expenditure; and yet the army was not numerous; the superintendence of the finances had been given to an obscure and rapacious Italian, who had recourse to money edicts. The money due to the magistrates was not paid; some quarters of the annuities were retrenched; murmurs broke out; the parliament opposed the court; and a civil war was on the point of being kindled. An arrest of union between the courts of Paris gave the minister uneasiness, and was annulled by the council. The magistrates maintained that their union could not be regarded as unlawful, or reprehensible; upon which Mazarine replied, "The king must be obeyed; if he forbid wearing tassels to band strings, it is less the nature of the thing prohibited, than the prohibition, which constitutes the crime." The parliament appealed the situation of the intendants of the provinces who were instituted by Louis XIII.; on which the court, filled with indignation, resolved to have recourse to a very bold measure. During the celebration of Te Deum for the victory of Lors, a president and counsellor who had distinguished themselves in the debates, were arrested by order of the Cardinal; upon which the people rose, threw chains across the streets, formed barricades, fired on the chancellor's coach, killed some soldiers, and the two prisoners were liberated.

The coadjutor, archbishop of Paris, afterwards the celebrated Cardinal de Retz, fomented and took advantage of these disturbances: he was a man of a restless, intriguing, and seditious character; excessively profligate in his principles and manners, but possessed of very superior talents. He was jealous of Mazarine, at the same time that he despised his abilities. Thinking himself better qualified to fill the place of prime minister, he employed all his talents and his powers of intrigue to inspire the nobles with the same jealousy of Mazarine, which filled his own breast; at the same time, he inflamed the people and roused them to sedition, by representing the ignominy of submitting to the oppressive administration of a stranger. The parliament of Paris warmly seconded his pretended views of reformation; and a civil war was inevitable.

The talents of Mazarine were by no means equal to the approaching danger; and Anne of Austria, entirely under his guidance, was nearly as unpopular as himself. She could not appear publicly in the streets without being insulted; she was continually reproached with sacrificing the good of the nation to her attachment to a foreigner; and ballads and madrigals were sung in the street, on the subject of her amours. The women took an active and zealous part at this crisis; many of the most celebrated generals declared for or against the court, as they were ordered by their respective mistresses. In consequence of this state of things, and of their apprehension of greater danger, the queen regent, along with her children and Mazarine, left Paris, and retired to St Germains. Here, according to Voltaire, their distress was so great, that they were obliged to pawn the crown jewels in order to raise money: the king himself was often in want of common necessaries; and the pages of the chamber were dismissed, because they had not the means of maintaining them. The parliament now proceeded to extremities; they declared the Cardinal a disturber of the public peace, and an enemy to France: this was the signal of revolt; a separation of parties took place. The Frondeurs, as the rebels were called, were headed by the Prince of Conti, brother of the great Condé, and the Dukes of Beaufort, Bourbon, and Longueville. The Prince of Condé, though dissatisfied with the court, engaged in the royal cause, and joined the Queen at St Germains. But the rebels wasted their time in disputes, or vain parade, and neglected to take measures even for the defence of the capital: they were soon therefore thrown into alarm, when the Prince of Condé, at the head of 6000 troops, advanced against it. The Marshal Turenne, who had been allured by the Duchess de Longueville, sister of Condé, in vain attempted to defend Paris with an undisciplined rabble. A conference was agreed to; and a treaty concluded at Rouel, by which a general amnesty was granted, and the appearance of peace restored, without, however, any sincerity of reconciliation or extirpation of hatred on either side.

The court returned to Paris, and the Cardinal was received with joy by that very people, who, such a nobility, very short time before, had threatened his life. It is this levity of the French nation,—the absurd and contemptible mixture of a frivolous gallantry with the intrigues of state, and even with civil commotions,—and the influence exercised by the Duchess de Longueville and other women of a libertine character, in making the most eminent leaders several times change sides, that mark out these civil wars, otherwise contemptible, as objects of interest and study to those who wish to gain a minute, profound, and intimate acquaintance with the character of the French nation.

In 1650, the Prince of Condé repeatedly insulted the Queen and the Cardinal, while, by his haughtiness, he
disguised the coadjutor who now supported Mazazine, and by whose advice the prince, together with his brother the Prince of Conti, and the Duke of Longueville, were arrested at the council table. The citizens of Paris, on this occasion, celebrated with public rejoicings the imprisonment of these men, whom they had lately hailed as their deliverers. Mazazine, however, had not gained prudence, and his triumph, of course, was of short duration. Conceiving himself secure, he affronted the Duke of Orleans, who immediately deserted the court, and became the head of the Fronde. On this, the parliament again took courage, and demanded the liberty of the Prince of Conti, and the Duke of Longueville; and passed sentence of perpetual banishment against the Cardinal, who went in person to liberate the princes, in the hope of gaining their favour; but they treated him with contempt. He was then obliged to flee to Ligue, and afterwards to Cologne. The coadjutor this time remained faithful to the court; and by his intrigues, the Duke of Bouillon and Marshal Turenne were detached from the Fronde.

In 1651, Mazazine again entered the kingdom with 6000 men, upon which Condé took up arms, and the parliament declared him guilty of high treason, though he was only going to oppose the Cardinal, against whom they had so very lately passed a sentence of perpetual banishment. Condé, in this extremity, quitted Paris, to arm in his support the provinces of Guienne, Poitou, and Anjou, and to ally himself with the Spaniards.

During these convulsions, Louis XIV. being now of age, ordered the parliament to remove to Fontaine, and a few of the members obeyed; but the greater part remained. Thus there were two parliaments; their resolutions, however, had now fallen into such contempt, that the rival factions disdained their mediation or support, and prepared to terminate their differences by the sword. Condé, in league with the Spaniards, appeared in the field against the king, and the Marshal Turenne supported the court.

The opposing armies approached each other on the banks of the Loire, when the Prince of Condé attacked the ranks of the royal army, with so much impetuousity, that they were broken. The court took the alarm; and the minister proposed to save the king by flight. This plan, however, was strongly opposed by Turenne, who, taking advantage of every inequality of ground, restored the confidence and the hopes of his party. The Prince of Condé, in the mean time, entered Paris, where he was at first received with joy; but the Cardinal of Retz, having deserted the popular cause, and succeeded in gaining an absolute sway over the Duke of Orleans, persuaded that Prince to become a candidate with the citizens for their favour, in opposition to Condé. In this he succeeded, and the Duke of Lorraine deserting the cause of the Prince at the same time, while his troops were exercised by the pleasures of the capital, Condé was not sorry to learn that the approach of Turenne presented to him the means more congenial to his talents and habits, of establishing his cause by the force of arms. In the suburbs of St. Antoine, the two greatest generals of France were opposed to each other: the King from an eminence beheld the battle. The Duke of Orleans remained in his palace, undecided what part to take: Cardinal de Retz was likewise neutral, and the parliament waited the issue, before it published any decree. The citizens of Paris, afraid of both parties, or affecting to preserve a strict neutrality, shut the city gates, and would permit no ingress or egress. The combat was long and bloody: the two generals performed wonders at the head of a few men; many gallant noblemen were killed or wounded; at last the battle was decided in favour of the Prince of Condé, by the daughter of the Duke of Orleans ordering the gates to be opened for the wounded, and the cannon of the Bastile to be fired on the king's troops. Turenne was in consequence compelled to retire. "These cannon have killed her husband," observed Mazazine, when informed of the circumstance, alluding to the hopes which the daughter of the Duke of Orleans entertained of being Queen of France.

The Duke was now declared by the Parliament lieutenant-general of the king, and the Prince of Condé commander in chief of the armies of France. But the popularity of the latter was of short duration: a tumult, in which several citizens were killed, and of which he was supposed to be the author, together with his violent and haughty demeanour, disgusted and irritated the inhabitants of Paris, and he was obliged to leave that city. On the other hand, Louis, in order to appease his subjects, dismissed Mazazine, who retired to Sedan. The people, satisfied at this mark of their sovereign's attention to their wishes, of their own accord sent deputies to invite him to return to the city, which he entered amidst the acclamations of persons of all ranks. The first acts of the royal authority were the banishment of the Duke of Orleans, and the arrest and imprisonment of Cardinal de Retz. The Prince of Condé, condemned to lose his head, abandoned in France by almost all his partizans, feebly supported by the Spaniards, and pressed by Turenne, carried on an unsuccessful war on the frontiers of Champagne.

To the storms of this civil war succeeded a calm. The Parliament was humbled; and Mazazine being recalled, again resumed all his authority, and was courted by every body. Even the Parliament, that had before set a price upon his head as a public robber, now sent deputies to compliment him. The Prince of Condé, after this absurdl war was finished, observed that it deserved only to be written in blank verse; and Voltaire remarks, that the name of Petits maîtres originally applied to that prince's party, because they endeavoured to make themselves masters of the state, and now signifying overbearing and frivolous young men; and the name of Frondeurs, bestowed on the censors of government, are the only vestiges remaining of these troubles.

Some parts of the kingdom were still in the power of the insurgents. Bellegarde, a town in Burgundy, was defended for the Prince of Condé, by the Count de Bouteville, afterwards known as Marshal Luxemburgh. It was attacked by the Duke of Epernon at the head of a royal army, but not surrendered till a practicable breach was made, and honourable conditions granted. In 1654, the Prince of Condé, in conjunction with the Archduke, laid siege to Arras. At the same time, Steen was besieged by Turenne. As soon as the latter place had surrendered, the Marshal, and De la Ferte, encamped in the neighbourhood of the Spaniards, and used every stratagem to induce, or oblige them to abandon the siege of Arras, but without effect. Shortly afterwards, Turenne having been reinforced, resolved, contrary to the opinion of his principal officers, to force the Spanish lines. The Spaniards were driven out with great slaughter, and lost their baggage, artillery, and ammunition; but the Prince of Condé, with two regiments alone, after defeating a division of his opponents, covered the flight of the Spaniards, and thus saved the remains of their army. The King of Spain acknowledged and characterized his services in a short
and expressive letter, "I am informed that all was lost, and that you saved all."

In 1655, Landreci and Quesnoy were reduced by Turenne, and thus a road was opened into the Spanish Netherlands. In the subsequent year, he invested Valenciennes with an army of 20,000 men. The lines were completed, and the operations far advanced, when the Prince of Condé, and Don John of Austria, advanced with a superior army, and in the night-time forced that part of the lines where the Marquis de la Ferte commanded. Turenne, after in vain endeavouring to restore the fortune of the battle, effected a masterly retreat, carrying off his artillery and baggage, and even halting on the approach of the enemy. In less than a month afterwards he took Capell, in sight of the Prince of Condé and Don John.

A short time before these events, Mazarine, more anxious about the overthrow of his enemies, and the restoration of tranquillity to France, than about the preservation of that country's honour, had formed a treaty with Cromwell, by which the Protector agreed to send the Cardinal a strong reinforcement, on condition that Charles II. and his brother the Duke of York, the grandsons of Henry IV. who had sought and obtained an asylum in France, should be ordered to quit it, and that the Cardinal should deliver up to England, Marilyke, Gravelines, or Dunkirk, whichever should be first wrested from the Spaniards. Turenne, after having in vain endeavoured to make himself master of Cambrai, into which, after he had encompassed it, the Prince of Condé penetrated at the head of 3000 horse, marched towards St. Quintin, to meet the English auxiliaries. With these he reduced Montmede and St. Vincent, raised the siege of Arde, and concluded the campaign by taking Marilyke, which, according to the treaty, was given up to the English.

In 1658, in compliance with the urgent request of Cromwell, Turenne was ordered by Mazarine to besiege Dunkirk, while the port was blocked up by an English squadron. The Prince of Condé, and Don John, came to its release. Turenne quitted his lines to encounter the enemy; and the Prince of Condé, whose advice was not followed, anticipated the disastrous consequences, observing to the Duke of Gloucester, who was with him, that if he had never seen a battle lost, he would see one now. The English and the French charged with rival valour; the Spaniards were totally defeated with the loss of 9000 of their best soldiers, and pursued even to the gates of Furnes; but the troops under the immediate command of Condé, effected their retreat in tolerable order. Ten days afterwards Dunkirk surrendered, and Louis entered in triumph; but he was soon obliged to deliver it up to Lockhart, Cromwell's ambassador. Furnes, Dixmude, Oudenarde, Menin, Gravelines, and Ypres, also were reduced. The success of Turenne alarmed the court of Spain, and induced it to think of peace; nor was Mazarine averse to it, one of the great objects of his policy being to obtain for the House of Bourbon the eventual succession to the Spanish monarchy. With this view, he had formerly proposed peace to Philip IV. on condition that a marriage should take place between the Infanta and Louis XIV.; but as the King of Spain had at that time only one son, an unhealthy infant, the proposal was rejected, lest the Infanta, if she succeeded to the throne of Spain, should carry her right to an enemy. Now, however, as Philip had another son, he agreed to the proposal of Mazarine. A cessation of arms was immediately resolved upon; and, in order that the preliminaries of a treaty might be settled in the most satisfactory manner to each party, Mazarine, and Don Louis de Haro, met on the frontiers of both kingdoms, in the Isle of Pheasants, in the Pyrenees, A.D. 1659. Much time was consumed in disputes about precedence; but at length the conferences were begun, and, after four months, were concluded by the celebrated treaty of the Pyrenees. According to this treaty, Louis received with the Infanta a dowry of 500,000 crowns of gold; Alsace and Roussillon were confirmed to him; and he restored the duchy of Lorraine to Charles IV.; and St. Omer, Ypres, Menin, and Oudenarde to the Spaniards; he also consented to pardon the Prince of Condé, and solemnly renounced all claim to any territory that might fall to him in right of his queen. The King of Spain, on his part, pardoned the rebellious Catalans; gave up Vercelli to the Duke of Savoy; Reggio to the Duke of Modena; and the Duke of Newburgh, the long disputed succession to the city of Juliers, which had been sequestered by the house of Austria.

On the 9th of March 1661, a little more than a year after the treaty of the Pyrenees, Cardinal Mazarine died; and his concern for his wealth was marked, even in the last moments of his life. By a deed of gift, he resigned his riches to the king, who immediately restored the instrument. His immense wealth was soon dissipated by the prodigality of the Marquis of Meillrai, who had married his favourite daughter, or niece, Hortensia Mancini, and assumed the title of Duke of Mazarine. On the ruin of her husband, Hortensia retired to England, and subsisted on a pension allowed her by Charles the Second.

"Historians have seldom done justice to the character of Mazarine, whose political caution restrained the vigour of his spirits, and the lustre of whose genius was concealed beneath his profound dissimulation. If his schemes were less comprehensive, or his enterprises less bold than those of Richelieu, they were less extravagant. He has been accused of avarice, and seemingly with justice; yet, if we reflect, that, being an indigent foreigner himself, he married seven nieces to French noblemen of the first distinction, and left his nephew Duke of Nevers, we shall, perhaps, be inclined partly to forgive him. So many matches could not be formed without money; and the pride of raising one's family is no contemptible passion. He had the singular honour of extending the limits of the French monarchy, while France was distracted by intestine hostilities; and of twice restoring peace to the greater part of Europe, after the longest and most bloody wars it had ever known. Nor must we forget his attention to the Spanish succession, which afterwards made the house of Bourbon so formidable to its neighbours, and is a striking proof of his political foresight. His leading maxim was, that force ought never to be employed but in default of other means; and his perfect knowledge of mankind, the most essential of all mental acquisitions for a minister, enabled him often to accomplish his views without it. When absolutely necessary, we have seen him employ it with effect."

On the death of Mazarine, the officers of state inquired of Louis, to whom they were to apply; 'They were self-governed, surprised and disappointed, when the monarch answered, 'to me.' He was at this time 22 years of age; he had been ill educated, and was consequently ignorant; addicted to pleasure, and had been carefully kept at a distance from all knowledge of business by the cardinal;
but he had measured his own powers of mind; and he already felt the first aspirations after that glory, which was the ruling passion of his life. He had also many circumstances in his favour, and which could not fail of impressing the minds of his subjects with loyalty, respect, admiration, and even esteem. He was remarkably handsome in his person, at the same time that there was about him a wonderful degree of majesty and dignity; these, which of themselves might have only inspired awe, were softened and tempered by affability and politeness; so that, if he was not the greatest king, he was at least, as Bolingbroke expresses it, "the best actor of majesty that ever filled a throne."

His dignity of mind, and loveliness of ambition, even induced him to render his pleasures more delicious to him if they would have been, had he been destitute of these qualities; and his court, following the example of the sovereign, was soon distinguished by its elegant galantry. The French have always been characterised by their fondness for show, and their vanity: these he gratified in an uncommon degree, by the magnificence of his palaces, and the splendour of his public entertainments. Even his own want of literature was concealed, or forgotten, in the patronage he extended to literary men, not only in his own kingdom, but also over the rest of Europe. These qualities rendered Louis extremely popular with the great majority of his subjects; while, with the more discerning, his reign was hailed with pleasure, as soon as the measures of Colbert began to operate towards the advantage of France, and Louis, by the confidence he placed in this minister, discovered that his objects extended beyond mere pleasure or glory. Though the king in other respects had no reason to be grateful to Mazarine, who had frequently misled him, and had neglected his education, and the formation of habits necessary for his high and arduous situation; yet he had received one favour from him of great moment, when he inspired him with confidence for Colbert, one of the greatest statesmen that France has produced. Fouquet, superintendent of finances, who dissipated the public money, was disgraced and imprisoned, after a sumptuous entertainment which he gave the king at his pleasure house, that is said to have cost him 18 millions of the then current money. His successor Colbert, had only the title of comptroller general. He soon put the finances into excellent order; raised enormous sums for the public service; and created a navy, and supported a large standing army, without oppressing the people.

Two occasions soon presented themselves, on which Louis had an opportunity of displaying his vanity, haughtiness and ambition. A dispute respecting precedence, that happened between his ambassador and that of Spain, in London, furnished the first occasion: The latter at a public entry insulted the former, because he would not yield the precedence; upon which Louis threatened to commence hostilities, unless the superiority of his crown was acknowledged. Philip yielded, and dispatched Count Fuentes to Paris, with the important concession, that the ministers of Spain should no longer dispute the precedence with those of France. His treatment of the Pope was still more arrogant. The Duke of Acqui, ambassador of Louis XIV. behaved in such a haughty manner, as to be quite intolerable; and his domestics followed the example of their master. Some of them having attacked the Corsican guard of the Pope, one of the pages of the ambassador was killed. On this the Duke left Rome. The French troops were put in motion towards Italy, and the Pope was obliged to send his nephew into France, to ask pardon, and to allow a pillar to be erected in Rome itself, as a monument of his own humiliation, and of the triumph of the French monarch. Even England experienced the lofty spirit of Louis: he absolutely refused to pay the honours of the flag; and when Charles remonstrated, he made such vigorous preparations to support his refusal, that the English monarch deemed it prudent to desist. "The King of England," said he to his ambassador D'Estreux, "may know the amount of my force; but he cannot measure the elevation of my mind. Everything to me is contemptible in comparison with glory.

Soon after his accession, he purchased Dunkirk from the needy King of England. He immediately employed 30,000 men to fortify it by land and sea; and dug a large basin between the town and the citadel, capable of containing several men of war. He soon afterwards obtained, by menaces, the strong hold of Marsal from the Duke of Lorraine; secretly supported Portugal against Spain; and openly gave his assistance to the Dutch against the King of England; though the latter offered to abandon to him all the Spanish Netherlands, provided he would not prevent him from pursuing his advantages over the United Provinces. In 1667, the Peace of Breda took place; but Louis was preparing for war. In six years he had accumulated a large sum of money, created a navy, augmented his armies, and provided large magazines, and an immense quantity of military stores. While Colbert regulated the financial department of the kingdom, his other favourite minister, Louvois, directed his genius most successfully to the means of supporting large armies at a distance by magazines. To lead these armies to victory, the Prince of Condé and Marshal Turenne were still in the vigour of life.

Louis, however, during this interval of peace, did not confine his attention and his labours solely to the means of carrying on future wars with advantage and success. He embellished the capital, and paved and lighted it in a magnificent manner; and, for the security of the citizens, established a police, which, from its vigilance and systematic proceedings, soon became the astonishment of Europe. In the provinces, highways and useful works were constructed. In 1664, the canal of Languedoc was begun. In 1666, a council for the reformation of the laws was established. In 1667, the civil ordinance was published; and soon afterwards the code of the waters, forests, the criminal ordinance, &c. followed. Duels, severely prohibited, became less frequent every day.

We have seen that, by the treaty of the Pyrenees, France solemnly renounced all title to the succession of any part of the Spanish dominions, which might arise in consequence of the marriage of Louis with the Infanta of Spain; but on the death of his father-in-law, Philip IV, the French monarch, pretending that no contract could do away a right derived from nature, restored his renunciation, and laid claim to a part of the Spanish territories. As Philip had left a son, Louis could not advance a claim to Spain itself; but he discovered that there was in Brabant an obsolete law or custom, by which a female of a first marriage was preferred to a male heir of a second marriage; and on this feeble and questionable ground, he claimed the Spanish Netherlands from the son of Philip by a second marriage. Voltaire mentions, that he formed a secret treaty with the emperor, who consented that he should seize on the Spanish Netherlands, on condition that
Louis would agree that the Spanish monarchy should revert to him on the death of Charles II. Circumstances were favourable to Louis' claims on Brabant. Besides his own vast preparations, Mary Anne of Austria, regent of Spain, was a very weak and superstitious woman, entirely governed by her confessor, a German Jesuit, whom she appointed grand inquisitor, and placed at the head of her councils. Under such persons, it was not surprising that the internal management and the external defence of the kingdom were neglected. Louis seized on the opportunity thus presented to him, and with an army of 40,000 men, dispersed by news of his order, and supplied by Louvois, in 1668 he invaded the Netherlands. The towns, nearly destitute of magazines or garrisons; and their fortifications in a dilapidated condition, surrendered as soon as summoned. Lisle alone resisted for nine days; and the king returned to Paris, after having left garrisons in all the towns, and directed the celebrated Vauban to fortify them.

The jealousy of the Prince of Condé was roused by the success of Turenne; and, finding that Louvois regarded that general with the same feeling, he proposed, even in the midst of winter, the invasion of Franche Comté, a province dependant on Flanders, or rather a kind of republic under the Spanish dominions, and which was attached to its sovereigns because they did not interfere with their particular privileges, and ruled them with mildness. But Condé did not trust entirely to the force of his arms; secret measures were employed; traitors were found. Besançon and Salins, the two strongest towns, were reduced in a very short time. In four days Dole surrendered; in three weeks of the month of February, the whole province was conquered.

The rapid success of Louis in the Spanish Netherlands and Franche Comté, alarmed the other powers of Europe, and a triple league was formed by Holland, England, and Sweden, for the purpose of repressing his ambition. Louis, apprehensive of a more powerful combination, offered to give up his queen's rights to Brabant and likewise Franche Comté, provided he might keep the conquests he had made last campaign; and the peace of Aix-la-Chapelle was formed.

At the congress for concluding this peace, the deputies from Holland had insulted Louis in a manner that monarch was not likely to forget or forgive. "Do you not rely on the king's word?" said, one day, the French minister to Van Lennep, the Dutch ambassador—"I do not know what the king will do," replied he, "but I know what he can do." This affront was aggravated by another circumstance: the States ordered a medal to be struck, on which a pompous inscription informed the reader, that the republic had conciliated kings, and restored tranquillity to Europe.

To motives of ambition, which alone were sufficient to stimulate Louis to war, were now added, in the case of Holland, the feelings of wounded pride. Under the joint influence of these, he prepared to humble the Dutch. He began by detaching Charles II. of England from his alliance with that republic, and bribing him to join France against it. Charles XI. of Sweden joined the league; and even the Bishop of Munster, greedy of war and plunder, and long an enemy to the Dutch, readily concurred in the measures concerted for their destruction.

At this period of danger, Holland was divided and weakened by two factions: the one headed by John de Witt, a stern republican, of great talents and integrity; the other by the Prince of Orange's partizans, who wished to invest him with the powers and the dignities of his ancestors. De Witt, however, had the command of the resources of the republic at the time when Louis prepared to invade it; and he was blamed for neglecting the land forces, and directing his whole care to the marine. Even after he knew that the French monarch projected an invasion by land, he seems to have been deceived with respect to the side on which it would be made; for he had taken his precautionary and defensive measures almost exclusively on the side of Maestricht. Louis, however, having made an alliance with Cologne, chose that quarter for commencing his little operations against him, as it was not necessary to enter the territories of the Duke of Lorraine, on which, as he had no hopes of gaining the consent of the Duke, he resolved to seize; endeavouring to justify his conduct on the unsupported and frivolous ground, that intrigues dangerous to the French monarchy had been carrying on at the court of Lorraine. Before he entered the territories of the Dutch, he issued a declaration of war against them. In this he did not condescend to specify particulars, but contented himself with the general and haughty assertion, that the insolence of the Dutch had been so great, that it did not consist with his glory any longer to bear it.

Holland was now threatened with a greater force than had ever been directed against her. The combined fleets of England and France, amounting to upwards of 100 sail, was ready to ravage her coasts; and a French army of 120,000 excellent troops, assisted and directed by the talents of Turenne, Condé, Luxemburg, and Vauban, was preparing to enter the frontiers. Louis passed the Meuse at V__). and in a very few days, having made himself master of the intervening towns, approached the Rhine. The season was extremely favourable to him; the greatest rivers were almost dried up by the excessive drought; the French cavalry, animated by the presence of their sovereign, plunged into the stream, and were feebly opposed by the Dutch; so that the passage of the Rhine was accomplished with no danger or difficulty. In little more than a month, the provinces of Guelderland, Overysssel, and Utrecht, were in possession of Louis; and the only difficulties remaining were in the provinces of Holland and Zealand. The king here committed an error: instead of pressing forward with his whole force, as he was advised to do by Condé and Turenne, he prevailed upon by Louvois to add new fortifications to his conquests, which, acquiring additional garrisons, necessarily weakened his main army.

In the mean time, the Dutch were successful at sea, De Ruyter having defeated the combined fleets of England and France in Solbay.

The Prince of Orange, unable to withstand the victorious and greatly superior armies of Louis, retired with his dispirited troops into the province of Holland. Naarden, within nine miles of Amsterdam, was reduced by the Marquis of Rochefort; and had he taken possession of Meyden, the keys of which were delivered to some of his troops, but recovered by the magistrates, Amsterdam must have fallen. Louis himself, instead of pushing forward, remained at Utrecht, wasting his time in vain parade. At this period, John de Witt proposed that the States should sue for peace; and carried his proposition, notwithstanding the Prince of Orange was decidedly averse to it. But the deputies were received by Louvois with excessive hauhtiness; and the intolerable conditions were insisted on, that the States should give up all their possessions beyond the
Rhine, and some strong places in the very heart of the republic; that they should restore the Roman Catholic religion, and every year send an ambassador to Paris, acknowledging that they held their liberty of France. The deputies instantly rejected these most absurd and humiliating conditions; and, on their return to Amsterdam, John de Witt and his brother were sacrificed by the populace as the authors of their calamities. The Prince of Orange was now chosen Stadtholder, and the most implicit confidence and obedience were shown him by all parties. As soon as Louis and his ally Charles perceived the effect which the appointment of the Prince of Orange had produced on the determination of the Dutch, they endeavoured to corrupt him by offering him the sovereignty of Holland; but he rejected all their proposals, and prepared for war. The country was inundated; preparations were made to embark for their East India colonies, if their country could not be saved. Providence itself seemed to interfere, by preventing the hostile fleet, with an army on board, from approaching the shores; and Louis, having gained sufficient glory, and finding that his progress was delayed, had returned to Marseilles.

In 1673, a confederacy, consisting of the Emperor and Spain, which had been alarmed at the conquests and ambition of the French monarch, and had already secretly assisted the United Provinces, openly declared themselves their allies. In three obstinate but indecisive actions, with the fleets of France and England, De Ruyter maintained his character, and protected his country by sea. As soon as the summer commenced, Louis resolved the command of his armies, and in 13 days took Maestricht, one of the strongest bulwarks of the United Provinces. The Prince of Orange, in the mean time, having assembled a respectable army, laid siege to Naarden; and, by its reduction, inspired his countrymen with confidence in his talents, and with hopes of the success of their cause. As soon as Naarden was reduced, he marched to join the Imperialists, who, under Montecuculi, on the banks of the Rhine, was opposed to Turenne. The Imperialists having in vain attempted the passage of that river, in the face of the Marshal, eluded his vigilance, however, and sat down suddenly before Bonne; here they were joined by the Prince of Orange, who had displayed equal talents, in leaving behind him the other French generals. Bonne soon surrendered; and by the fall of several other places in the Electorate of Cologne, the communication between France and the United Provinces was cut off, and Louis was obliged to recall his forces, and abandon his conquests.

In 1674, the Parliament of England obliged Charles to make peace with Holland; and soon afterwards this Monarch offered his mediation to the contending powers. The King of France readily acceded to the offer; but the Prince of Orange, who had great influence in the councils of the United States, and had just obtained the perpetual grant of the office of Stadtholder for his family, and who, besides, was ambitious of military fame, refused the mediation, alleging that it would be in vain to negotiate, till a greater impression had been made upon France. Louis, therefore, resolved to open the campaign with such accumulated means, as should render this expectation of the Stadtholder altogether fruitless. He brought three great armies into the field; one on the side of Germany, one in Flanders, and one on the frontiers of Roussillon, while he himself, at the head of a fourth, entered Franche Comté, and subdued the whole province in the space of six weeks. The attacks on Besançon were directed by Vauban, who was so great a master of those operations, and besides found every thing necessary so well supplied by Louvois, that it was reduced in nine days. In Flanders, the Prince of Condé, who commanded the French army, was opposed by the Prince of Orange; the former, though his forces were inferior in number, prevented the latter from penetrating into France; and at last attacked the rear of his army, in a narrow defile at Senneffe. Having entered into confederacy with the great part of their cannon and baggage. On this occasion, the Prince of Orange, sensible that he had been out-generalled, stoned for his mistake by his personal exertions and courage; he rallied his troops—led them back to the charge; in his turn made the French retire; and obliged Condé to exert desperate efforts to obtain the victory, which he at length achieved. Such were the deeds of the Prince of Orange in this battle, that his adversary, always candid and magnanimous, remarked, "The Prince of Orange has acted in every thing like an old captain, except exposing his life too like a young soldier." At length the night parted the combatants, and, notwithstanding the advantage which the French obtained at the commencement of the engagement, the victory remained undecided. The Prince of Orange, however, in order to give himself the appearance of having been the conqueror, or to bring the French to a new engagement, besieged Oudenarde; but the Imperial general, who was with him, not choosing to hazard a battle, the siege was raised. Before the close of the campaign, however, he reduced Grave, the last town that the French held in any of the United Provinces.

In Alsace, Turenne commanded, and displayed much military skill against a superior army. By a rapid and well-concerted march, he attacked and defeated the Duke of Lorraine, and Caprara, the Imperial general, at Sintzium; and afterwards entered the Palatinate. During his absence in Lorraine, the Imperialists again returned, and with an army of 70,000 men, entered and overran Alsace. This obliged him to come back for the defence of this province; and so unexpected was his arrival, that the Imperialists, taken unawares, were completely defeated, and being dislodged, were obliged to repass the Rhine. The Palatinate was now given up to the most wanton and barbarous destruction. From his castle at Manheim, the Elector beheld two cities and 25 towns in flames. Insipine and lust vied with each other in the dreadful destruction that they committed. The Elector, mad with rage and grief, challenged Turenne to single combat; but the Marshal coolly replied, that he could not accept such a challenge without his master's leave, but would, at any time, meet the Elector in the field, with their respective armies.

In 1675, Montecuculli was recalled and placed at the head of the Imperial army, in order to oppose Turenne. He endeavoured to penetrate into Alsace, Lorraine, or Burgundy; while Turenne endeavoured to defeat this design. The most consummate skill was displayed on the banks of the Rhine, the scene of their manoeuvres, by these two celebrated generals, who had reduced war to a science. Turenne, by posting himself on the German side of the river, not only kept his rival from passing it, but was in a situation to take advantage of any fortunate circumstance that might occur. At last he thought that such a circumstance presented itself; and was preparing to bring the Germans to a decisive engagement, by reconnoitering a situation to erect a bat-
During these various operations, a congress had been established at Nimsgen, under the mediation of the King of England. The Dutch were tired of the war, which had greatly increased their taxes; but the Prince of Orange, filled with ambition and animosity against France, persuaded them to continue it, representing, among other reasons, that it was necessary to obtain a strong frontier on the side of Flanders, and that they could not honourably desert their allies. Louis also was desirous of peace; but as he wished for favourable conditions, he was sensible that these could be obtained only by a vigorous prosecution of the war. Thus the negotiations leading to no result, the preparations for a new campaign were carried on with great activity on each side. Louis took the field, as usual, as early as February, Louvois having by this time established large magazines. Valenciennes was his first object, which he carried by storm, by making the assault in the morning, when it was least expected, in preference to the night, the usual time; to this he was advised by Vauban. Indeed, he never sate down before any place that he was not almost certain of reducing. He next invested Cambray and St Omers. The Prince of Orange advanced to the relief of the latter place, with an army hastily assembled; the siege was covered by the Duke of Orleans, the King’s brother, and Marshal Luxembourg; the former had the effeminate manners of a woman, but these concealed the most ardent courage; the latter had been the intimate friend and favourite pupil of Condé. The Prince of Orange being resolved to raise the siege at any rate, an obstinate battle was fought at Mont Capel, on the 11th of April: For some time the issue was doubtful, till Luxembourg made a masterly movement, which compelled the Prince to seek shelter under the walls of Ypres. The fall of St Omer (which immediately followed) caused, amongst others, Flushing, after military fame, and jealous of it in others, could not brook the idea that his brother should have gained a victory by an army, of which he was the commander; he listened to the intelligence with no marks of satisfaction, and never afterwards entrusted the Duke with the chief command. The Prince of Orange, in order to compensate for his defeat, laid siege to Charleroi, but he was forced to raise it on the approach of Marshal Luxembourg.

Negotiations for peace still continued, and they were soon brought to a favourable termination. The Parliament of England obliged Charles to listen to pacific overtures, as they, as well as the nation, were strongly averse to the union with France, especially for the purpose of war against Holland. The Dutch were weary of the war, from which hitherto they had derived no advantage, which could compensate for their additional taxes. France also needed peace; for though victorious on the field, she was exhausted at home. The King had indeed taken the field early in 1678, and had reduced Ghent, while the army under Luxembourg had invested Mons, when the Dutch ambassador at Nimsgen, alarmed at the progress of the enemy, signed the treaty of peace with the ministers of France, by which Louis secured the possession of Franche Comté, Cambray, Aire, St Omers, Valenciennes, Tour- nay, Ypres, Bouchain, Capel, Charlemont, &c. Maestricht was restored to the United Provinces. Spain re-
covered Charleroi, Oudenarde, Aeth, Ghent, and Liemburgh. The Emperor gave up Fribourg to the French, but retained Philipseburg. Lorraine was offered again to its Duke, but he chose rather to become a soldier of fortune than accept it under the conditions which Louis insisted upon. The Dutch ambassador, in signing this treaty, had not consulted the Emperor or the King of Spain, both of whom subscribed to the conditions with great reluctance. The Prince of Orange was equally averse to it; and pretending that he did not know that peace was actually signed, he attacked and gained some advantage over Marshal Luxemburg, who concluded the war was terminated, and consequently did not expect this attack.

Very soon after the peace, the Emperor, Spain, and the United Provinces, disbanded their armies; whereas Louis kept up a formidable force. His motive for this was too soon apparent. Several territories which had formerly been dependant on the three bishoprics of Metz, Toul, and Verdun, and on Alsace, had been for a long time in possession of different German Princes, and Louis wished to unite them to the crown of France. For this purpose he established two chambers, at Metz and Brissac, and these tribunals not only passed a decree for the union which the King wished, but even cited the neighbouring princes, and the King of Spain, to appear before them, and render homage to the King of France, or to submit to the confiscation of their possessions. The Elector Palatine, and the Elector of Treves were deprived of the seignories which they held in this part of Germany. But Louis made a still more daring and unjust attempt the next year, A. D. 1681. Strasburg, a powerful city, which commanded the Rhine by its bridge, was still free, and Louis had long been extremely desirous to annex it to France. Money and threats had been employed in vain,—the magistrates absolutely refused to give it up. At last, by the advice of Louvois, troops were ordered into Lorraine, Alsace, and Franche Comté, under the pretence of employing them to work on the fortifications in these provinces. They all assembled in the neighbourhood of Strasburg, amounting to 20,000 men, and took possession of the ground between the Rhine and that city, as well as of the redoubt that covered the bridge. Louvois, who was at their head, now demanded that the town should be placed under the protection of France. The magistrates, being intimidated or corrupted, and the inhabitants in consternation, the city opened its gates. Its ancient privileges were secured. Vauban was ordered to repair and strengthen its fortifications, and he soon rendered it one of the strongest places in Europe.

Louis conducted himself with equal violence and injustice towards the Spaniards, pretending that his minister had forgotten to insert the cession of the county of Alost, in the Low Countries, in the treaty of peace, he demanded that it should be given up to him; and as his demand was not instantly complied with, he besieged Luxemburg. Such proceedings, manifesting a determination not to be bound by any treaty, and violent and unjust to themselves, alarmed the other powers. The Emperor, King of Sweden, and some other princes, had already endeavoured to rouse the German empire; and if the Elector of Brandenburg had not at that time supported France, war would have recommenced. A congress, however, was held at Frankfort, for the purpose of inquiring into Louis' proceedings with regard to the German territories, which he had annexed to France. To this congress, his pleni-

potentiaries presented a memorial in the French language. Great disputes arose from this circumstance, Latin having heretofore been the universal language of diplomacy. As there were also other disputes on points equally frivolous, the congress was dissolved, and the business put off till the meeting of the diet at Ratisbon. In the mean time, the French monarch had reduced not only Luxemburg, but Courtray and Dixmude. Upon this, the Spaniards declared war; but they were not supported by any other power. A truce of 20 years was therefore concluded at Ratisbon, by Spain and the Emperor with France, by which Louis agreed to restore Courtray and Dixmude; and was allowed to retain possession of Luxemburg, Strasburg, the fortress of Kehl, and part of the territories which his arbitrary courts at Metz and Brissac had adjudged to him.

Still Louis displayed undoubted proofs of his determination not to continue long at peace; and even while at peace, to augment his power by unjustifiable as well as justifiable means. He paid particular attention to the increase of his navy, and the enlargement and improvement of his ports. He had upwards of 100 sail of the line, and 60,000 seamen. The port of Toulon was constructed; Dunkirk and Brest were repaired, and rendered more fit for the purposes of holding ships of war; and Rochefort, in spite, as it were, of nature, was converted into a convenient harbour. Squadrons were employed against the African pirates: bomb-ketches, which had been newly invented by a Frenchman, were used against Algiers in 1681, and again in 1684. This piratical state, as well as those of Tunis and Tripoli, experienced and acknowledged the power of Louis. Genoa next felt his wrath. This republic was accused of selling powder to the pirates, and building galleys for Spain. The city of Genoa was bombarded; and some of its palaces reduced to ashes. The Doge and four of the principal senators were obliged to go to Paris and implore the clemency of Louis, who, in order to prevent the Genoese from depriving him of any part of his triumph, insisted that the Doge should be continued in office, notwithstanding the law of the republic, by which a Doge was deprived of his dignity the moment he quits the city. When the Doge was asked, what he thought most extraordinary at Versailles? he replied, "To see myself there!"

In 1683, Colbert died. The advantages which he Death of had secured to France, were great and numerous: he Colbert. restored her finances, and established or invigorated her principal manufactures. Subsequent events proved how much France was indebted to him; since, when he ceased to manage the finances, the military successes of Louis languished. As he found that the Protestants, no longer able to oppose the government, or to distinguish themselves by their valour in the field, were disposed to direct their attention to manufactures, he protected and encouraged them. Their industry and industry were rewarded by opulence; and their opulence rendered them the objects of the envy and the jealousy of their Catholic brethren. After the death of Colbert, they were exposed to a persecution at once unjust and impolite, which terminated in the revocation of the edict of Nantes. Even before this, the Protestants were excluded from all civil employments, and rendered incapable of holding any share in those very manufactures, which they had carried to such an extent and perfection, as to have rendered them the sources of great individual and national wealth. After the death of Colbert, they were placed entirely at the mer-
of the Chancellor Tellier, and his son, the Marquis de Louvois, whose leading maxim was, that every person should tremble at the name of the king. In 1684, they sent troops into the Protestant districts; and Louvois wrote, that it was his majesty's pleasure, that all who did not conform to his religion, should suffer the greatest severities. By the revocation of the edict of Nantes, liberty of conscience was abolished; all the Protestant churches were destroyed; and an order was issued even to take their children from them, and put them into the hands of their Catholic relations. The ministers were banished; and the others were proscripted from striking the kingdom, which the law inflicted on them such unjust and cruel persecution. All the terrors of military execution were employed to make them profess the Catholic religion; and such as relapsed, were exposed to the most dreadful punishments. A twentieth part of the whole body was put to death in a short time; and a price was set on the heads of the rest, who were hunted like wild beasts. Above 500,000 of the most useful and industrious inhabitants of France were driven into exile, by the revocation of the edict of Nantes; and thus the staple manufactures of France not only declined in that country, but were transferred to other nations by these exiles. At the very same time that Louis, out of zeal for the Catholic religion, was thus persecuting the Protestants, he was insulting the Pope, and depriving him of Avignon. The cause of his insulting the head of the Catholic religion, sufficiently proves that Louis was actuated more frequently and strongly by ambition, and a desire to exercise his power, than by any other feeling or principle; and that, even on the most frivolous or unjust pretences, his ruling passions sought opportunities of displaying themselves. The Pope Innocent XI. was a man of talents and abilities; and was extremely anxious to destroy an abominable privilege which rendered nearly one half of Rome an asylum for all sorts of criminals, the ambassadors of Catholic princes in that city extending their right of protection to a great distance from their dwellings. He was also anxious to root out another privilege, by which whatever entered Rome under the sanction of an ambassador's name paid no duty; and thus the trade of the city suffered, and the revenue was defrauded. Several of the Catholic sovereigns, on the representation of the Pope, gave up the abuse of these rights. Louis was next applied to; but he answered, that he never acted after the example of others, but would himself set an example to them; and accordingly he sent his ambassador to Rome, with such a number of guards, as should protect him in the full exercise of these most unjust privileges.

Such proceedings could not fail to excite the apprehensions of the other potentates of Europe. The Emperor Leopold having succeeded in defeating the Turks, in reducing the Hungarian malcontents, and in securing to the House of Austria the hereditary possession of the throne of Hungary, resolved to oppose the power of Louis. The Prince of Orange, who seems to have had a habitual and cherished hatred of Louis, readily entered into the views of the Emperor; and the league of Augsburg was formed, in order to restrain the encroachments of France, and to secure the objects of the treaties of Westphalia, the Pyrenees, and Nimzegen. Spain, Sweden, Denmark, and Savoy, afterwards joined in it from love and interest. Louis, apprized of the designs of these powers, resolved to strike the first blow; and accordingly sent the Dauphin, at the head of 100,000 men, into Germany. After a siege of 19 days, Philipsburg was reduced; Manheim, Frankenthal, Spiers, Worms, and Oppenheim, also surrendered; and the Palatinate was again given up to the plunder and devastation of the soldiers, A.D. 1689. Men, women, and children, were driven out into the fields, in the midst of a severe frost, and left to perish of hunger and cold; while their houses were reduced to ashes, their property seized, and their possessions pillaged. More than 40 cities, and an infinite number of villages, were burnt; the palaces of the electors were razed to the ground, and their very windows were thrown out in search of hidden treasures. The second devastation made the former one under Turenne appear mild and merciful. About this time, England was added to the number of Louis's enemies. James II. had been deposed, and William Prince of Orange chosen in his stead. Louis sent a fleet to Ireland, with troops to support the dethroned monarch. William gladly seized this opportunity of rousing the parliament and people of his new kingdom against Louis.

The exertions of the French monarch, though great, were not commensurate with the strength and number of the states that opposed him. He had nearly 400,000 men in the field. The army of Spain and the United Provinces, after it was reinforced by the English under the Earl of Marlborough, amounted to nearly 50,000. The Emperor and the German states supplied three armies; one under the Elector of Bavaria, who commanded on the Upper Rhine; the main army under the Duke of Lorraine, on the Middle Rhine; and the third on the Lower Rhine, under the Elector of Brandenburg. The Duke of Lorraine took Munts, and the Elector of Brandenburg took Bonne, while the Prince of Waldeck obliged the French, under Marshal D'Humieres, to hazard a battle at Walcourt, in which they were defeated. The next year, A.D. 1690, Louis gave the command of this army to Marshal Luxemburg, who, in the plains of Fleurus, defeated the Prince of Waldeck, with the loss of 6000 killed, and 8000 taken prisoners. The Dutch infantry behaved so gallantly on this occasion, that the Marshal observed, "Prince Waldeck ought always to remember the French cavalry; and I shall never forget the Dutch infantry." In Italy, the Duke of Savoy, the celebrated Victor Amadeus, was opposed by the Marshal de Catinat, who had been bred to the law, but whose superior genius soon rendered him an excellent general. He completely defeated the Duke at Staffarada; and in consequence of this victory, the whole of Savoy, except the fortress of Montmelian, was reduced by the French. Catalonia was the scene of hostile operations, in which also the French were successful. But what was more extraordinary, and more flattering to the ambition of Louis, the combined fleets of Holland and England were defeated off Beachy Head, by the French fleet under Tournville.

In the beginning of April 1691, Louis himself took Mons, in defiance of King William. Nothing farther remarkable happened on the side of Flanders. In Italy, Marshal Catinat was held in check by Prince Eugene; on the frontiers of Germany, the war languished; and in Catalonia, the advantages gained by the French were neither splendid nor decisive. The following spring, Louis and William set out on the same day to join their respective armies. Namur was reduced, even in the sight of William, by Louis, with an army, of 45,000 men; while Luxemburg, with another army covered the siege. The reduction of this place was rendered remarkable by the circumstance, that Coehorn defended in person a new fort, while Vauban directed the attack. In order to atone for his not having prevented the fall
of this important town, William endeavoured to surprise the French army under Luxemburg, at Stein- kirk; but after the most daring efforts, he was compelled to retreat. The next year, he was yet more unfortunate; the army of the confederates being defeated with the loss of 8000 men at Landen; Huy and Charleroi fell into the possession of the French, in consequence of their success at Landen. In the mean time, the French fleet under Tournville, who received express and positive orders to fight, that, if victorious, he might invest and garrison, was defied near Cape de Hogue, by the combined fleets of England and Holland.

In the campaigns of 1694 and 1695, fortune seemed rather to favour the allies: Huy was retaken; the Duke of Savoy penetrated into Dauphine; and King William, taking advantage of the death of Marshal Luxemburg, invested Namur, which, though it was gallantly defended, was obliged to capitulate in the sight of the French army under Villeroi. About this period, a dreadful famine afflicted France; it was caused partly by unfavourable seasons, and partly by the war not having left labourers sufficient to cultivate the ground. Corn was brought from abroad; and if this had been the only measure adopted, probably the calamity might have been in some measure alleviated; but by attempts to regulate the price, the evil was increased; many of the peasants perished of hunger, and the whole kingdom exhibited a dreadful scene of poverty and distress.

In consequence of the misery of his people, and the exhausted state of his finances, Louis perceived the necessity either of making peace, or of detaching some of the members from the confederacy. He preferred the latter. A negotiation was opened with the Duke of Savoy, who was induced to desert the allies, and to unite himself to Louis, in consideration of the restitution of his dominions; the honours of sovereignty; four millions of money; and the marriage of his daughter with the young Duke of Burgundy, son of the Dauphin. The campaign of 1697 was not distinguished by any remarkable occurrence, except the taking of Barcelona by the Duke of Vendome, notwithstanding it was gallantly defended by the Prince of Hesse Darmstadt, with a garrison of 10,000 men. This event induced the King of Spain to listen to the proposals of France. A congress for a general peace was opened at the Castle of Ilyswick, under the mediation of Charles XI. of Sweden. The Emperor at first was unwilling to listen to terms of accommodation, but finding himself deserted by his allies, he acceded to the treaty. By this treaty, Louis restored to the Spaniards all the places he had taken from them; but the pretensions of the House of Bourbon to the Spanish succession were left in full force. He acknowledged William lawful king of England; with regard to Holland, he adhered to the terms fixed at Münster and Nimèguein. To the empire he restored Kehl and Philippsburg; and to the Emperor, Friburg and Briese: he even consented to destroy the fortifications of Strasburg on the Rhine; and restored Lorraine, Treves, and the Palatinate, to their respective princes.

This peace was very unpopular in France, particularly with the inhabitants of Paris, who reproached and insulted the ministers who made it, on their return to the capital; but these people looked only to the victories which the French arms had gained, not to the effects of such an expensive war on the resources of the country, and yet they were very obvious, and plainly pointed out a peace as absolutely necessary. The five first campaigns had cost more than 200,000,000 extra-ordinary; the finances were in the greatest disorder; that the people might not be oppressed with taxes, recourse was had to loans, to the erecting new offices, and to other measures, which in the end became more extensively and permanently oppressive than additional taxes. The value of the silver mark in coin had been increased three livres in 1689; by which the commerce was injured, the kingdom impoverished, individuals unjustly treated, and the revenue sensibly diminished. In 1695, the capitation tax was established; by it 21,000,000 were raised, but they were at the expense of the other taxes, for the revenue of this year was not on the whole increased.

It has been noticed, that the succession to the throne of Spain, which was claimed by the Bourbon family, was not settled by the terms of the peace of Ilyswick; and scarcely was that peace concluded, before it was evident that hostilities would soon recommence from this cause. The King of Spain, a prince equally weak in body and mind, was on the point of dying without children. According to the strict and just rights of consanguinity, only the Imperial or French families had a claim to the throne; but there was another competitor, who founded his claim on a will. The three competitors were, Louis XIV. the Emperor Leopold, and the Elector of Bavaria. Louis and the Emperor were both grandsons of Philip III.; in this respect therefore their claim was equally strong; but the right of birth was in the House of Bourbon, the king and his son the dauphin being both descended from the eldest daughters of Philip III. and Philip IV. respectively. The Imperial family, however, asserted, in support of their claim, the solemn and repeated renunciations of Louis XIII. and XIV. and the blood of Maximilian, the common parent of both branches of the House of Austria. The Elector of Bavaria claimed, as the husband of the only surviving child of the Emperor Leopold by the infanta Margaret, second daughter of Philip IV. who had declared her descendants the heirs of his throne, in preference to his eldest daughter's descendants; so that the will of Philip IV. must be set aside, before the claim of the Elector could be rendered null.

In the mean time, a most extraordinary circumstance occurred. William, King of England, who was always so jealous of the power of Louis,—who had used his utmost efforts to restrain or crush it,—and who seemed actuated even by a personal dislike to that monarch,—concluded a partition treaty with him, A. D. 1698, by which it was stipulated, that, on the death of the King of Spain, his dominions should be divided among the claimants, in the following manner: Spain, and all her American possessions, were to be given to the Elector of Bavaria; the kingdom of the Two Sicilies, the ports on the Tuscan shore, and the Marquisate of Flandre, were to be given to the Dauphin; while the Emperor's second son, the Archduke Charles, was to receive only the dukedom of Milan. As soon as intelligence of this treaty reached the court of Madrid, the King of Spain made a will in favour of his grand nephew the young prince of Bavaria, who died almost immediately afterwards. Upon this, the disquiets and intrigues were renewed; and a second treaty of partition was signed February 8th, A. D. 1699. This treaty differed materially from the former. Spain and the West Indies were to be given to the Archduke Charles; the Milanese to the Duke of Lorraine, who was to annex Lorraine to France; and the Dauphin was, as before, to have the Two Sicilies, the ports on the Tuscan shore, and Final.
To prevent the union of Spain and the Imperial throne in one person, it was agreed that the Archduke should not succeed to the Spanish throne, in case he was raised to the dignity of king of the Romans, by the death of his eldest brother. On the other hand, in order to prevent the annexation of Spain to France, it was stipulated, that no dauphin or king of France should ever be king of Spain. But the Emperor, expecting the succession to the whole Spanish monarchy, rejected the treaty of partition. The King of Spain nominated the Archduke Charles his universal heir; so that it was evident that the partition treaty would be of no effect, unless the parties who had signed it had recourse to arms; and it was highly probable, that if war took place, Louis would grasp at more than his share, and thus defeat the very object for which he had signed the treaty: indeed, he was already taking measures to gain a strong party at Madrid; for whereas the arrogance of the Queen of Spain, and the grossness and rapacity of her German favourites, disgusted the Spanish nation, a powerful and favourable impression was made on them by the infallibility, insinuating address, and generosity of the French ambassador, the Marquis D'Harcourt.

The efforts of the Marquis were unintentionally seconded by the Emperor and his son. The former refused 10,000 men, which the King of Spain requested of him, in order to put himself in such a position as would have made the projectors of the treaty respect the independence of the Spanish monarchy; and the Archduke spoke of the Spaniards in reproachful terms. The clergy supported the claims of the House of Bourbon. Even the Pope was consulted, and he answered, that the laws of Spain, and the good of Christendom, required that the House of Bourbon should be preferred. Influenced by this opinion, Charles secretly made a will, in which he nominated the Duke of Anjou, second son of the Dauphin, successor to all his dominions. This prince was preferred, as less likely to unite in his own person the crowns of Spain and France. The King of Spain died some months afterwards.

Louis at first was undecided, whether he should adhere to the partition treaty, or accept the will of the King of Spain. At last, by the advice of his council, he accepted the will, and the Duke of Anjou was crowned at Madrid, under the name of Philip V. His grandfather, at parting with him, exclaimed, "There are no more Pyrenees!" He was acknowledged by the Pope, the Duke of Savoy, Venice, the northern potentates, and even Portugal, England, and Holland. Such indeed was the general astonishment at seeing a Bourbon prince on the throne of Spain, that for some time all the powers, except the Emperor, remained in perfect tranquillity. But the King of England was soon roused against France, by the insulting conduct of Louis towards him and the English nation; for on the death of James II., the French monarch proclaimed his son as James III. William upon this, finding that his subjects were equally inimical to himself, conciliated the Grand Alliance, as it is called, against Louis. This famous treaty was signed on the 17th of September 1701, by the plenipotentiaries of the Emperor, the King of England, and the United Provinces; its object was to prevent the union of France and Spain, and the French taking possession of the Spanish dominions in America; to obtain satisfaction to the Emperor respecting the Spanish succession; and to secure and protect the dominions and commerce of the English and Dutch. But the death of the King of England, the main spring of this treaty, threw the allies almost into despair, and occasioned the most indecent joy at the court of France. The succession of Anne, however, and her immediate declaration that she adhered to the grand alliance, revived the hopes and the fears of the confederates and the French.

Even before the grand alliance was formed, war had begun in Italy between France and the Emperor. Prince Eugene, who commanded the Imperial army of 50,000 men, penetrated through the district of Trent; the French general Catinat not conceiving himself authorised to obstruct his passage, in consequence of orders from his court. The Milanese was thus exposed to danger; and Catinat was replaced by the Marquis of Villeroi. This general imprudently attacked Eugene, and was defeated. The first campaign, after the formation of the grand alliance, was not distinguished by any great event. In Italy, Eugene was not able to follow up his successes, as his army was greatly inferior to the combined forces of France and Spain; indeed, he was obliged to raise the blockade of Mantua, and was defeated in attempting to suppress the French general Vendome near Lugano. On the upper Rhine, the Prince of Baden was defeated by the Marquis de Villars, who, for this victory, was immediately afterwards created a marshal of France. On the side of Flanders, the cause of the Bourbons was not so prosperous. The Earl of Marlborough, by his masterly movements, succeeded in getting between the enemy and the principal towns of Spanish Guelderland, and reduced such of them as opened the navigation of the Maese, and a free communication with Maestricht. By sea, Louis was unfortunate, the English having destroyed at Vigo a fleet of galleons, which had an immense quantity of money on board. In the beginning of 1703, the Duke of Savoy, who had been long wavering, concluded a treaty with the Emperor. On the 30th of September in that year, the Imperialists were defeated with great slaughter at Hochstet, by Marshal Villars and the Elector of Bavaria. The consequences of this victory were the reduction of Augsburg, and the opening of a passage to Vienna itself. About the same time, the Duke of Burgundy made himself master of old Brissac; and, before the end of the campaign, Marshal Tallard retook Landan, and defeated the Prince of Hesse, who was advancing to its relief.

Soon afterwards, Louis was under the necessity of revoking Marshal Villars, in consequence of a revolt in the Cevennes. This revolt was occasioned by the persecutions of the Protestants, who, roused by some pretended prophets and prophets, were maddened with religious fury and enthusiasm. Their war-cry was, "No taxes, and liberty of conscience!" The more they suffered, the greater was their invertebracy and constancy. They principally inhabited lonely and desolate mountains, from which they rushed like wild beasts, and to which they returned when they were pursued or attacked. Marshal Villars, ashamed of having been recalled from scenes of real glory to war against these people, and moreover finding that they could not be completely subdued, thought it better to treat with one of their chiefs, a young baker, to whom the rank of colonel was given. The rebels, however, did not submit at this time; but they were afterwards reduced, and almost exterminated by the Duke of Berwick.

During the absence of Villars, Marshal Tallard was entrusted with the command. The lines of the Elec-
FRANCE.

The Duke of Marlborough having returned to Flanders, Villars was employed in watching the numerous armies of the empire on the Rhine, and succeeded in baffling them by his skill. In Italy, the Duke of Vendôme pressed on Prince Eugene and the Duke of Savoy; bought the bloody but indecisive battle of Cassino; and menaced Turin with a siege. These advantages of the French were balanced by the good fortune of the allies in Spain, where the Archduke Charles, whom they proclaimed king, made himself master of most of that country.

In 1706, the Marshal Villeroi was defeated by the Duke of Marlborough at Ramillies; and the greatest part of Spanish Flanders rewarded the victors. Louis, instead of reproaching, endeavoured to console the Marshal for this defeat; "People at our time of life, Monsieur Marshal," said he, "are not fortunate." In Italy, the siege of Turin was begun by the Marshal Feuillerade, son-in-law of the minister Chamillard. The siege was covered by the Duke of Orleans, the nephew of Louis, who was however controlled by the superior, but secret powers of the Marshal Marsin. As the preparations for this siege were immense, great expectations were formed of its success; but Feuillerade was by no means fit for his situation; he was ignorant, obstinate, and so conceited, that when Vauban offered to direct the operations of the siege as engineer, he rejected the offer with disdain. The city, however, notwithstanding the incapacity of the Marshal, was reduced to the greatest distress, when Prince Eugene rapidly approached to its relief. The Duke of Orleans wished to have left his lines, and met the enemy; but he was overruled by Marshal Marsin, and the French waited the attack in their entrenchments. In two hours, the Prince obtained a complete victory: the Duke of Orleans was wounded, Marshal Marsin killed, and the duchies of Milan, Mantua, and Piedmont, with the kingdom of Naples, were by this one battle wrested from the House of Bourbon. The affairs of Louis in Spain were equally desperate; but in a short time fortune changed sides there, and Charles was obliged to evacuate his capital, and fly before the Duke of Berwick, who triumphed at Almanza over the forces of the confederates.

Louis having in vain endeavoured to engage the King of Sweden in his cause, began seriously to think of putting an end to a war, by which his arms had been disgraced, and his subjects impoverished. He accordingly ordered the Elector of Bavaria to write letters to the Duke of Marlborough, and the field deputies of the United Provinces, proposing a general congress; offering, as a proof of his sincerity, to give up all the Spanish dominions in Italy to the Archduke Charles; to the United Provinces, a barrier in the Netherlands; and to the Duke of Savoy, a compensation for the waste made by the war in his territories. In return, he asked the restoration of Bavaria to its native Prince; and that Philip V. should be allowed to possess Spain and her American colonies. This offer was, however, indignantly and wantonly rejected, the views of the allies extending with their successes. Having humbled France, they now wished to conquer Spain. They accordingly informed Louis, that no peace could be made with the House of Bourbon, so long as a prince of that house sat on the throne of Spain.

Louis was not so humbled in means or in hopes, as to be willing to accept these conditions, and he resolved to prosecute the war with vigour; but he was at a loss for money. In this emergency, he issued bills upon the mint to a very large amount, but most foolishly refused to take them in payment of taxes. The consequence was, that they fell into such discredit, as to be at more than 50 per cent. discount. He therefore was obliged to continue the practice of loans, and to anticipate the royal revenue. Still his efforts were astonishing: The coasts of the Channel and Mediterranean were defended by a line of militia; an army was stationed in Flanders, under the Duke of Vendôme; another in the neighbourhood of Strasburg, under Villars; two smaller armies were collected in Navarre and Roussillon; and the Duke of Berwick, who still commanded in Spain, was strongly reinforced. These reinforcements came from Italy, where the French troops, amounting to 15,000 men, had been obliged, by capitation, to evacuate Lombardy.

In Spain, the House of Bourbon was successful. The Duke of Orleans, who assumed the command after the battle of Almanza, reduced Valenta and Arragón, and took Lerida; but Marshal Villars, having passed the Rhine, laid Swabia and Franconia under contribution. France itself, however, was exposed to danger in the midst of these successes; for Prince Eugene and the Duke of Savoy, being perfectly at liberty, in consequence of the French army having evacuated Lombardy, formed a plan, in conjunction with the maritime powers, to reduce Toulon or Marseilles. But, unfortunately for the allies, before the Prince appeared with the van of the Imperialists, the French had found means to throw 8000 men into Toulon, the place which they ultimately had resolved to attack. They had also taken possession of all the eminences that commanded the city; and the allies, in attempting to dislodge them, were repulsed with considerable loss. In consequence, the generals deemed it prudent to give up the attempt. Incidentally, however, this expedition was detrimental to France; for the detachments drawn from the army of Marshal Villars for the defence of Toulon, obliged him to abandon his projects against Germany, and to repass the Rhine.

In the month of July 1708, the French army under the Duke of Vendôme was defeated by the Duke of Marlborough at Oudenarde. Immediately after this battle, the former were joined by a strong reinforcement under the Duke of Berwick from the Rhine, and the latter by Prince Eugene's army. The siege of Lisle, the principal city in French Flanders, and the second in the dominions of Louis, was now besieged by the allies; Eugene being engaged with it directly, and Marlborough covering the siege. Into this place Marshal de Bouhoy, an old experienced officer, had thrown himself with some of the best troops of France; but notwithstanding his gallant efforts, and his utmost skill, in the space of two months he was Lisle taken obliged to capitulate. In Italy, the Duke of Savoy at the attempted to pass through Switzerland, in order to join the troops of the empire in Alsace, and penetrate into France on that side; but he was so vigorously opposed

History.
by Villars, that he was content with securing his own
dominions against the invasions of the enemy, by re-
ducing Exiles, La Porse, and Fenestally.

In consequence of the reduction of Lisle, a road was
opened to the very gates of Paris; and the citizens
were insulted and alarmed by the predatory excursions
of the enemy; of course, they became discontented and
weary of the war; and their discontent and misery were
increased and participated by the other inhabitants of
France, from the circumstance of a severe winter oc-
curring, which destroyed the grain and the olive trees,
and threw over their prospects, already gloomy, the cer-
ainty of a partial famine. Louis, therefore, was
compelled to direct his thoughts to peace. In 1709,
he agreed to yield the whole Spanish monarchy to the
House of Austria; to cede to the emperor all that he
had conquered on the upper Rhine; to give Furnes,
Ypres, Menin, Tournaï, Condé, and Maubeuge, as a
barrier to the United Provinces; to acknowledge the
Elector of Brandenburg as King of Prussia, and the
Duke of Hanover as the ninth elector of the empire;
to remove the Pretender from France, and acknow-
ledge Queen Anne; to restore every thing required by
the Duke of Savoy; and to agree to the cessions made
to the King of Portugal, by his treaty with the confe-
derates. But the allies, thinking that the moment was
arrived when Louis might be still more effectually
humbled, demanded, in addition to these terms, his
agreement to certain preliminary articles, which were
not only so degrading in themselves, but couched in
such dictatorial language, that he resolved not to con-
sent to them; threw himself upon his people, and, by
explaining the ample concessions which he had offer-
ed, roused their indignation and pride. Hostilities
therefore were continued. The army of the allies,
amounting to 100,000 men, under Eugene and Mar-
borough, were opposed to Villars, who had been called to
the command as the last hope of his country, and who
was strongly and advantageously posted between Cour-
riere and Bethune. The allies, after reconnoitring his
position, were afraid to attack him, and set down be-
fore Tournaï; which, notwithstanding the strength
both of the town and the citadel—the latter of which
had been constructed by Vauban—fell into their power
in the course of a month. They now formed the plan
of besieging Menin, which Villars, on his part, resolved to
attempt to save it; but not arriving there before the
allies, he took possession of a strong camp about a
league from the city, his right extending to the village
of Malplaquet. Here was fought a most obstinate
battle, in which Marshal Villars was wounded and car-
ried off the field, and the allies were the victors, though
their loss was nearly double that of the French. Mons
now fell, and its surrender concluded this campaign in
Flanders.

As soon as the season for hostile operations was at
an end, Louis renewed his applications for peace, and
conferences were appointed to be held at Gertruydenburg
early in the spring of 1710. At these the French mo-
narch offered additional concessions; but the allies, or
rather the Dutch deputies, to whom every thing was
left, were still haughty and imperious, insisting that
Louis, instead of paying a subsidy toward the war
against Philip V, which he had proposed, should assist
the confederates with all his forces to drive his grand-
son from the throne of Spain. Louis could not possi-
bly agree to this most humiliating and barbarous con-
dition; but, as he was extremely desirous of peace, the
conferences were not broken off. In the meantime,
the confederates continued their successful progress in
Flanders; Douay surrendered, the Marshal Villars hav-
ing in vain attempted to relieve it; Bethune, St Ve-
nant, and Aire, were also reduced. In Spain, the cause
of the Bourbons was rather successful, and with their
successes their dropping spirits revived. In 1711, a
change of ministry took place in England; by which,
the friends of the Duke of Marlborough were remo-
ved from their places, it was supposed that he also
would be deprived of his command. But probably the
war terminated; but, as the war was popular, and the
Duke a great favourite with the nation, the new mi-
istry did not deem it prudent immediately to recall
him, or terminate it. Another event however occurred,
which had still greater influence on the state of things;
this was the sudden death of the Emperor Joseph. He
was succeeded by his brother Charles; and as it was
counter to the general alliance that the same person
should possess Spain and the empire, the new ministry
of England were no longer afraid to avow their wishes
for peace. Hostilities however still continued; but
the rigour of the season prevented the Duke of Mal-
borough from taking the field before the beginning of
May; and, after he did take it, no events of importance
occurred. Negotiations had been for some time se-
cretly carried on between France and England, and
on the 27th of September they were privately signed
at London. As the allies were not informed of these
negotiations, they were highly indignant at the intel-
ligence that the preliminaries were signed. But, in
the beginning of 1712, general conferences were open-
ed at Utrecht for restoring tranquillity to Europe; the
French and English ambassadors declaring, that the
preliminaries signed at London were neither binding
on the Queen or her allies. While these negotiations
were going on, the Dauphin of France died; and his
eldest son, as well as his son, died also. In conse-
quency of these deaths, the Duke of Anjou, a sickly
infant, only intervened between the King of Spain and
the crown of France. It was now necessary to submit
certain propositions to Louis and Philip V respecting
Spain; the latter preferred the possession of the Span-
ish throne without hesitation, but Louis hesitated be-
fore he agreed to the choice of his grandson. He
at last complied; and it was agreed, that the renunciation
of the throne of France by Philip V should be regis-
tered in the books of the parliament of Paris, and rati-
fied by the cortes of Castile and Aragon.

While these negotiations were going on, Prince Eug-
ene proposed to the Duke of Ormond, who had suc-
cceeded the Duke of Marlborough, to attack the French
army under Villars, in the hope of concluding the war
with a splendid victory; but the English general having
orders not to act offensively, defeated, by his hesitation,
the projects of the prince, who, however, reduced Ques-
noy, and sent a detachment to penetrate into the heart
of France. Soon after this, the Duke of Ormond made
known to the allies the cessation of arms between France
and England, and separated the British forces from those
of the other confederates. Notwithstanding this di-
mination of his army, the prince invested Landreyc;
but on this occasion he committed errors, which were
perceived and taken advantage of by Marshal Villars,
who slaughtered or dispersed a body of 14,000 men near
Denain. The Marshal followed up this success; and,
having reduced Marchiennes, where the principal ma-
gazines of the confederates were deposited, he reco-
verted successively Douay, Quesnoy, and Bouchain. The
Dutch now, being sensible of their perilous situation
History.

France.

acceded to the plan of pacification settled between France and England. Their example was followed by the Duke of Savoy, the King of Portugal, and the Emperor; the last of whom, finding himself unable to support any military operations in Spain, agreed to the evacuation of Catalonia. Thus, as was mentioned before, all the belligerent powers, except the Emperor, being disposed for peace, negotiations were opened at Utrecht.

On the 8th of March 1713, the treaties were signed at Utrecht by the plenipotentiaries of France, England, Portugal, Prussia, Savoy, and the United Provinces; the King of Spain refusing to sign the stipulations, till a principality was provided in the Netherlands for the Princess Orsini, the favourite of his queen. So far as France was concerned, the principal articles were, that Philip V. should renounce all claim to the throne of that kingdom; that the Dukes of Berry and Orleans, the next heirs to the French monarchy after the infant Dauphin, should renounce all right to the crown of Spain, in the event of their accession to the crown of France; that the Rhine should form the boundary of the German empire on the side of France; and that the fortifications built or destroyed by France should either be relinquished to the emperor or destroyed; that Luxemburg, Namur, and Charle- roii, should be given to the United Provinces, as a bar- rier, along with Mons, Menon, Tournay, &c. already in their possession; that Lisle, Aire, Bethune, and Dinant, should be restored to France; that Louis should acknowledge the title of Queen Anne, and the eventual succession of the house of Hanover to the British throne; that the fortifications of Dunkirk should be demolished, and the harbour filled up; that New- foundland, Hudson’s Bay, and Nova Scotian, should be given up by France to England; and that the title of King of Prussia should be recognised by Louis, who should at the same time agree to cede to him the town of Gueldres, with part of Spanish Guelders.

As the Emperor continued obstinate, two months were allowed to him to sign the treaty; in the course of which, as Louis had now no other enemy, and Prince Eugene was not sufficiently strong to oppose Marshal Villars, the latter successively took Worms, Spire, and Landau; pierced the lines which the prince had or- dered to be drawn from the Brissag, and defeated General Vaubonne in his entrenchments. The Emperor now was anxious for peace, and conferences were opened between Prince Eugene and Marshal Villars at Radstadt.

The terms of this treaty, which was concluded on the 6th of March 1714, were less favourable to the Em- peror than those offered at Utrecht, as the King of France retained Landau, which he had formerly proposed to cede, and got the Electors of Bavaria and Cologne fully re-established in their dominions. About the same time, Louis persuaded the King of Spain to forego his absurd claim in behalf of the Princess Orsini, and to accede to the general pacification.

Louis did not long survive this peace: he died on the 1st of September 1715, in the 78th year of his age. The events of his reign sufficiently illustrate his charac- ter as a monarch. His love of glory and ambition were inextinguishable, and leapt over the boundaries of jus- tice and humanity, in order to attain its wishes. His courage has, however, been doubted; it is certain, at least, that he never exposed his person, and never, while he commanded the army, undertook the siege of a place which he was not certain to reduce, or fought a battle which he was not certain to win. It must be said in exculpation, that this love of glory and ambition, which led him to cause the destruction of so many of his fellow-creatures, and to despise the plainest and most powerful dictates of justice and humanity, also induced him to patronise and encourage every species of literature, science, and art; so that France was, in his time, equally illustrious, by the great military talents of her generals, and by the splendour of her men of science and literature. At the head of his armies were Turenne, Condé, Luxemburg, Catinat, Crequi, Bouf- flers, Montesquieu, Vendome, and Villars—and his fleets were commanded by Tourvile, Du Quene, and Du Guay-Trouin;—Colbert, Louvois, Torcy, and Pom- ponie, directed his counsels;—Bosmet, Bourdaule, and counters, taught him his duty;—Vauban fortified his towns; Biquet formed his canals;—Perrault and Mansard constructed his palaces, which were embellish- ed by Le Pousin, Le Sourd, and Le Brun;—Cornelle, Racine, Molire, Queuaut, La Fontaine, Bruyere, and Boileau, relieved his more serious cares, by their wit and literature;—and Fenelon, Huet, Flechier, Beaumillé, and Bosmet, were the instructors of his children.

This seems to have been the folly, if not the injustice, of his pursuits before he died; for he made use of the following memorable expressions to his successor—

"Endeavour to preserve peace with your neighbours; I have been too fond of war; do not imitate me in that, or in being too expensive. Take advice on all occa- sions, and endeavour to discover the best, that you may always follow it. Relieve your people as soon as you can; and do that, which unfortunately I could not do." He also advised him never to forget his duty to- wards God.

By an edict, which was registered in 1714, he called his legitimized children to the succession, failing the princes of the blood; but this edict was revoked in 1717.

The Duke of Orleans, soon after the death of Louis XIV. appealed to the decision of the Parliament of Paris against the will of that monarch, and was ap- pointed by them sole regent. Although excessively ad- dicted to pleasure, yet, in the early part of his adminis- tration, his measures were popular, wise, and bene- ficial. He restored to the parliament the right of re- monstrating against the edicts of the crown; compelled those who had plundered the people, by their extortions during the late reign, to give up their unjustly acquired wealth; repopulated the towns and districts that had been thinned by the ravages of war; nourished commerce and agriculture; and entered into a close alliance with Great Britain and the United Provinces. But his mea- sures were interrupted, and his power threatened, by the intrigues of the Cardinal Alberoni, first minister of Spain. This man, persuading Philip V. that his rec- nunciation of the throne of France was invalid, and that he had a better right to it than the Duke of Or- leans, in case of the death of Louis XV. endeavoured to inflame those who were discontented with the mea- sures of the Duke. But his plots having been dis- covered, his adherents in France were executed, and the Duke’s authority was henceforth more firmly estab- lished. Soon after this, the Duke formed the quadruple alliance; and Alberoni still continuing his intrigues, a declaration of war against Spain was issued by Great Britain and France. The Duke of Berwick, who had the command of one of the French armies, march- ed towards the frontiers of Spain, took possession of St Sebastian and Fontarabia; and having made prepa- rations for the siege of some other places in that king-
In 1723, the king being arrived at the age fixed for his majority, the Duke of Orleans resigned the regency, and was appointed minister, but he did not long survive. He was succeeded in the administration by the Duke of Bourbon, who was soon supplanted by Cardinal Fleury, who had been preceptor to Louis XV, and was now 73 years old. The character of the Cardinal was very different from that of statesmen in general. He was of a mild disposition, and regarded the preservation of peace as the greatest blessing which a sovereign couldbestow on his subjects. This blessing therefore he was extremely anxious, during his whole administration, to preserve; and, as Sir Robert Walpole, the minister of Great Britain at this period, was equally pacific, the tranquillity of Europe was continued, with little interruption, for nearly 20 years. At length, the death of the King of Poland, in 1733, rekindled the flames of war, and France was induced to embark in it, in support of Stanislaus, the father-in-law of Louis, (for the Infanta of Spain had been sent back, before the marriage projected by the Duke of Orleans was completed.) France, on this occasion, united with Spain and Sardinia, and hostilities commenced on the side of Germany and Italy. The Duke of Berwick passed the Rhine, but was soon afterwards killed before Philippsburg. In Italy, the Imperialists were defeated by the French; the Spaniards became masters of Naples and Sicily; and the forces of France and Italy, under Villars, took Milan and some other places. Soon after this, Villars died, and his successor, the Marshal de Coigny, defeated the Imperialists, under the walls of Parma.

The Emperor, discouraged by these losses, proposed peace; and Cardinal Fleury, sincere and constant in his wish for it, acceded to the proposal. By the treaty, Stanislaus was to renounce his pretensions to Poland, in consideration of the cession of Lorraine to him during his life; and Louis agreed to restore all his conquests in Germany, and to guarantee the pragmatic sanction, or domestic law, by which the succession to the hereditary dominions of the house of Austria were secured to the heirs female of Charles VI. in case he should die without issue. Soon after this peace, Charles VI. died; and the disputed succession to his hereditary dominions, notwithstanding the pragmatic sanction, kindled anew the flames of war in Europe. By virtue of this sanction, the succession to the whole Austrian dominions belonged to Maria Theresa, the late emperor's eldest daughter, who was married to Francis of Lorraine, Grand Duke of Tuscany. Almost all the European powers had guaranteed the pragmatic sanction; nevertheless, when the period came, in which it was necessary to support it, many of them took up arms to set aside the claims of the house of Austria, were the Elector of Bavaria, the King of Poland, the King of Spain, and the King of France; but the last did not appear as a competitor, being afraid of awakening the jealousy of all Europe. These claimants were, however, astonished, when the King of Prussia also appeared among them; and while they were inactive, actually invaded Silesia. Cardinal Fleury, notwithstanding this violent invasion of the pragmatic sanction, was still desirous of peace; but he was unable to withstand the ardour for war in the French councils; and this ardour was increased by the idea, that the period was at length arrived, so long desired by France, for breaking the power of the house of Austria, and exalting that of Bourbon on its ruins. A treaty with the Elector of Bavaria was accordingly concluded, by which the King of France engaged to assist him with his whole force, on condition that, if he succeeded in his projects, he would renounce the barrier treaty, and not attempt to recover any part of the empire, which France might have conquered; a treaty, was also concluded with the King of Prussia at the same time, the object of which was the demarcation of the possessions of the house of Austria. The Elector of Bavaria was appointed lieutenant general of the French armies, with the Marshals Belleisle and Broglio to act under him. Louis XV. at the same time, issued a hostile declaration against the King of Great Britain, in his character of Elector of Hanover.

The Elector of Bavaria was very rapid in his progress. Having entered Upper Austria, he took possession of Linz, and sent his detachments to the neighbourhood of Vienna itself. In this extremity, Maria Theresa roused the Hungarians in her behalf; their nobility were instantly in arms; and the Elector of Bavaria, threatened by the forces which Maria Theresa had collected, and finding the season of the year adverse to farther proceedings, gave up the plan of investing Vienna, and marched into Bohemia, where, being joined by 20,000 Saxons, he laid siege to Prague. After the reduction of this place, he was, on the 4th January 1742, elected Emperor, under the name of Charles VII. A.D.1742. Here, however, his good fortune terminated; the Prussians and Saxons having been unsuccessful, were obliged to retreat, and the Austrians seized this opportunity of attempting to unite their whole force against the
French, under Marshal Belleisle and Broglie. The King of Prussia, fortunately for the French, prevented their junction; but this monarch soon afterwards suspected the sincerity of his ally, the King of France, concluded a separate treaty at Breslaw. This unexpected and alarming Intelligence was followed by disastrous consequences; for Marshals Broglie and Belleisle, pressed by superior forces, were reduced to the humiliating necessity of offering to evacuate all the places which they held in Bohemia, provided they were permitted to retire with their arms, ammunition, and baggage. This proposal was haughtily rejected by the Queen of Hungary; and Marshal Maillebois, who commanded the French forces on the Rhine, was ordered to march into Bohemia, at the head of 42,000 men. In Westphalia, he was joined by 30,000 French and Imperialists. In the mean time, Marshal Belleisle, who had assumed the command in Prague, was closely pressed by the Prince of Lorraine. The latter, on learning the approach of Marshal Maillebois, turned the siege into a blockade, and advanced with the main body of his army towards the frontiers of the kingdom, in order to oppose the French. He was soon afterwards joined, by a large Austrian army, and in the mean time Marshals Belleisle and Broglie formed the design of uniting with Maillebois. Prince Charles, however, by taking possession of the passes in the mountains, utterly defeated this scheme; and Maillebois was obliged to return to the Palatinate, whither he was followed by the Prince of Lorraine; while the Austrian army, under Lobkowitz, obliged Belleisle and Broglie again to take refuge in Prague.

Soon afterwards, Broglie having escaped from this city in disguise, took upon him the command of the French army in the Palatinate; so that the fate of Prague, towards which the attention of all Europe was now directed, depended solely upon the conduct and courage of Belleisle, and the small remains of that gallant army, which had given an Emperor to Germany. Now it was that the powers and resources of Belleisle's mind were made manifest; having formed the plan of his retreat, by making in one quarter of the town a feint for a general forage, and marching out at another, he succeeded in eluding the besiegers, and in reaching the defiles with an unbroken army. In this march he had ten leagues to pass over; the ground was covered with snow; the cold intensely severe; all the inhabitants were his enemies: and as soon as his flight was known, Prince Lobkowitz with 12,000 infantry, and 8000 cavalry, hung on his rear. After a fatiguing march of twelve days, he reached Egra, and entered Alsace without the loss of a single man from the enemy, though a thousand had perished in consequence of the rigour of the season.

In 1743, the Queen of Hungary being victorious in Germany, and in possession of the territories of the Emperor Charles VII, the French became heartily tired of a war, in which they had suffered so severely, and made proposals of peace, on rather humiliating conditions. The victorious Empress no longer influenced the cabinet of Versailles: he had died in the beginning of this year. But the Queen of Hungary rejected all pacific overtures; and Louis made preparations for carrying on the war with increased vigour and effect. Affairs, however, were still gloomy: the French were driven from all their positions in the Upper Palatinate; and Marshal Broglie was obliged to abandon a strong camp on the Danube, and to retire towards the Rhine. When he reached Donawert, he was joined by 12,000 men under Count Saxe; but his main body being nearly ruined, he still continued his retreat. About this time, the battle of Dettingen was fought between the French and the English; for an account of which, see the article BRITAIN.

On the 25th of October in this year, a family compact, or perpetual alliance, was formed between France and Spain at Fontainebleau; in consequence of which the admirals of their combined fleet, in the harbour of Toulon, resolved to give battle to that of England, by which they had been blocked up. The particulars of this engagement are given in the article BRITAIN. Hitherto France and England, though actually engaged in hostilities, had not issued mutual declarations of war. These, however, were put forth towards the end of March 1744. For the particulars of this war, we shall refer our readers to the article BRITAIN; and in this place confine ourselves to the operations of France against Austria and Sardinia. About the beginning of April, the French and Spaniards formed the plan of penetrating into the Duchy of Milan, through the Genoese territories; but the republic not daring, in consequence of the threats of Admiral Matthews, to allow this passage, the French and Spaniards defiled off towards Piedmont, and attacked a strong post, where the King of Sardinia commanded in person. This post they carried; in consequence of which, the King of Sardinia drew off his troops, in order to cover his capital. In the mean time, the confederates invested Coni, the possession of which would have opened them a passage into Milan. The King of Sardinia, on learning this, having been reinforced by 10,000 Austrians, resolved to attempt the relief of the place. He accordingly attacked the French and Spaniards in their entrenchments; but, after an obstinate engagement, he was compelled to retire, not, however, before he had reinforced the garrison of Coni, and supplied it with provisions. As the winter was now approaching, the confederates raised the siege, repassed the mountains, evacuated Piedmont, and entered Dauphiné.

In the beginning of November, a treaty was concluded at Frankfort, through the influence of France, between the Emperor and King of Prussia, the King of Sweden, and the Elector Palatine, the declared object of which was to restore the imperial dignity, and the tranquillity of Germany, by persuading or obliging the Queen of Hungary to acknowledge Charles VII. The King of Prussia, however, by a separate agreement, was not obliged to take up arms, till he should see France act with vigour. In consequence of this agreement, Louis put himself at the head of his army in Flanders, consisting of 120,000 men, and invested Menin, which surrendered in seven days; several other places were reduced with equal facility; while the allied army, amounting only to 70,000 men, were posted behind the Scheldt. But Louis was soon obliged to leave the scene of his triumphs, to go and defend his own kingdom; for Prince Charles of Lorraine having passed the Rhine, entered Alsace with an army of 60,000 Austrians. Against him, the king dispatched first the Duke of Noailles, and afterwards marched himself; leaving Marshal Saxe, with part of the troops, to oppose the allies in Flanders. This general, though now inferior to them, yet, by his consummate abilities, prevented them from gaining any advantages during the remainder of the campaign.

Before the Prince of Lorraine could achieve any operation of importance, having got information that the King of Prussia had entered Bohemia, he judged it
prudent to repass the Rhine; after which, Louis laid siege to Fribourg, and the reduction of this place terminated the campaign on the side of Alsace.

In 1745, Charles VII, died; and his son being too young to become a candidate for the Imperial throne, concluded a peace with the Queen of Hungary. This treaty, it was expected, would lead to a general pacification, as the cause of war in Germany no longer existed; but the Marquis D’Argenson, the French minister, who had great influence in the cabinet, declared that France, having undertaken to give a head to the Germanic body, ought to hazard the last soldier, in support of what she claimed, and had declared she would do. The cabinet of Versailles therefore offered the Imperial throne to the King of Poland; but he refused it. The French were still obstinate; and as they could find no candidate of their own, they determined to continue the war, in order to prevent the election of the husband of Maria Theresa. The republic of Genoa, which had been long wavering in its politics, now concluded a treaty with the House of Bourbon, which turned out fatal to the interests of the Queen of Hungary and the King of Sardinia. The latter was obliged to retire, by the joint army of the French, Spaniards, and Neapolitans, beyond the Tanaro; the city of Pavia was taken by assault, and Milan itself forced to surrender. Turin was then threatened; but the confederates, contented with their success, closed the campaign by a triumphant entry into Milan.

Although the avowed object of Louis was to prevent the election of the Grand Duke, yet he had also in view the conquest of Flanders. In order to carry into execution both these plans at once, he assembled two great armies: one on the Maine under the Prince of Conti, and another under Marshal Saxe, which advanced to Tournoy. As the relief of this place was of great consequence, the allies, consisting of the Austrians, Dutch, Hanoverians, and British, though inferior to the French, resolved to attempt its relief. This gave rise to the battle of Fontenoy; for an account of which, see Britain. After this battle, while the allies were entrenched between Antwerp and Brussels, Marshal Saxe and Count Laudenhahl reduced Tournoy, Oudenarde, Ath, Dendermont, Ghent, Ostend, and every other fortified place in Austrian Flanders. But though thus successful in this object, Louis was less fortunate in the other object of the war; for he was not able to prevent the Queen of Hungary from raising her husband to the imperial throne.

By the treaty of Dresden, the King of Prussia was detached from the house of Bourbon; notwithstanding which, the King of France was determined to push his conquests in the Netherlands, while the King of Great Britain, enraged at Louis for supporting the Pretender, was equally resolved to oppose his projects. Louis commenced the campaign with his usual vigour. Marshal Saxe took Brussels in the beginning of February 1746. In April, the King joined his army, now 120,000 strong; Antwerp was reduced; Mons, one of the strongest places in Flanders, held out only a few weeks, and, by the 10th of July, Louis was master of Flanders, Brabant, and Hainault. The confederates hitherto not able to oppose the French, now mustered 87,000 men, under Prince Charles of Lorraine; and with this force they took up a strong position in the neighbourhood of Namur, as they conceived this place would be next invested. Marshal Saxe, after reconnoitring their situation, did not deem it prudent to attack it; but, in order to attain his object by other means, he reduced Dinant, and thus obtained the command of the navigation of the Meuse above Namur, while a large magazine of the confederates was captured at Huy. The communication being now cut off with Maestricht, Prince Charles, from a scarcity of provisions, was obliged to quit his post, and leave Namur to its fate. The garrison was numerous, and the place well defended; yet, on the 6th day, the town was compelled to surrender, and the citadel on the 16th. Marshal Saxe, who never lost a moment’s time, immediately after this passed the river Jaar, at the head of the whole French army, and attacked the allies in the villages of Leirs, Warem, and Roucoux, at the same time, by 35 battalions in brigades. As soon as one was repulsed, another advanced; so that the allies, wearied out, and, by some unaccountable neglect, destitute of artillery, were obliged to abandon the villages, and retreat towards Maestricht. The French, however, had suffered so much, that they did not attempt to pursue them. This battle was not attended with any important consequences: with it, the operations in the Low Countries terminated.

As soon as Louis learnt the defection of the King of Prussia, he made, without consulting the court of Madrid, such advantageous proposals to the King of Sardinia, that they were instantly accepted, and a cessation of hostilities took place; but the jealousy and indignation of the Spanish Monarch were so great, that the treaty was annulled. The consequence, however, was injurious to France, as, from the misunderstanding, the French and Spanish armies for some time effected nothing. The King of Sardinia, on the breaking off the treaty, made himself master of Asti, which was garrisoned by 5000 French troops. This proceeded still more to foment the jealousy between France and Spain, the French general being accused of treachery in not succouring this place. The Spaniards immediately raised the siege of Milan, and the French, afraid that their communication with Provence might be cut off, retired to Novi. This misunderstanding and jealousy being at last removed, the French and Spanish armies again united, and attacked the Austrian camp at St Lazaro; but they were compelled to retire, after suffering a very severe loss.

On the death of the king of Spain, the generals of the combined armies, doubtful in what manner his successor would act, were desirous of securing a communication with France, and accordingly commenced a retreat, which was conducted with great ability by the Count de Maillébois, son of the Marshal of that name. The King of Sardinia pursued, and endeavoured to harass them: at Rotto Fredo he brought them to battle, and defeating them, Placentia was obliged to surrender. The French and Spaniards next took shelter under the cannon of Genoa; but not deeming this situation secure, they left the city to its fate, and retreated, the latter into Provence, and the former into Savoy.

The King of Sardinia being desirous of turning the victorious Austrians aside from Italy, persuaded them, in conjunction with the British cabinet, to invade France by the Austrians. Count Bruni, who commanded the Austrians, accordingly invaded Provence; but, by the masterly conduct of Marshal Belleisle, he was under the necessity of repassing the Var. Towards the end of this year, the King of France discovered some wish to make peace, and a congress was opened at Breda; it came to nothing, however, as the French were exorbi-

history.  

Imperious preparations against Louis,  
A.D. 1748.

France, now freed from external war, was threatened with civil commotion, in consequence of religious disputes between the Jesuits and the Jansenists. These disputes had existed in the latter end of the reign of Louis XIV. when the bull Unigenitus, by which the opinions of the Jansenists were condemned, threw all France into the most violent commotion. The death of Louis XIV. however, put an end to the dispute; and as the Duke of Orleans would not allow the bull to be carried into effect, tranquillity was re-established.

In 1750, the disputes again broke out; the parliament and the people were inimical to the bull; the Archbishop of Paris endeavoured to enforce it, and Louis XV. at length prohibited the interposition of the Parliament. This body was not disposed to submit quietly, and the King at last banished the refractory members to different parts of the kingdom. In 1754, however, he found it absolutely necessary to recall them; and the Archbishop of Paris, and two bishops, were in their turn banished. A temporary calm was thus produced; but the dispute respecting the bull did not subside, and the King at length referred it to the Pope. The decision of his Holiness, that the bull ought to be acknowledged as an universal law, so enraged the Parliament, that they suppressed the Pope's brief by an arrest. This renewed the difference between them and their sovereign, who, in 1756, went to the Parliament with all his guards, and suppressed the 4th and 5th Chambers of Inquest. Upon this, 15 councillors of the Great Chamber, and 124 members of the other courts, resigned; and the King was again under the necessity of accommodating matters with the Parliament. Soon afterwards, the Jesuits were expelled, chiefly by the authority and influence of the Parliament, the members of which, elated at this victory over ecclesiastical tyranny, next attempted to set bounds to the absolute power of the crown. We have brought the history of these ecclesiastical disputes down beyond the period at which we broke off from the political history, both because it is thus rendered connected and complete, and because in it we may clearly trace the gern of those causes which afterwards produced the Revolution.

Almost immediately after the establishment of peace by the treaty of Aix-la-Chapelle, France began to discover projects of ambition, both in America and the East Indies. These were so glaring, and prejudicial to Great Britain, that, in 1755, that court began to prepare for hostilities. Preparations were also made by the court of Versailles. In 1756, France threatened the Electorate of Hanover; in consequence of which, Great Britain united herself with the King of Prussia, while France formed an alliance with the imperial court of Russia and Sweden. One of the first attempts of the French was the conquest of Minorca, which, not being relieved by Admiral Byng, they succeeded in reducing. In 1757, a French army of 80,000 men passed the Rhine, in order to invade the electorate of Hanover; while a smaller French force joined the imperial army on the Main. The Duke of Cumberland was invested with the command of the troops which were to protect Hanover; but, attempting in vain to obstruct the progress of the enemy, he was obliged to retire behind the Weser; and afterwards, on the 8th of September, to sign the convention of Closter-Severn. As
soon as the French general had thus gained possession of the electorate of Hanover, he formed a junction with the Imperialists. Their object was to drive the Prussians out of Saxony; and, for this purpose, they passed the Saal, and summoned Leipsic. The King of Prussia advanced against them, and fought the battle of Rossbach on the 5th of November 1757, in which he gained a complete victory. Towards the end of this year, the Hanoverians, roused by the oppressions of the French, and headed by Prince Ferdinand of Brunswick, succeeded in forcing them to repass the Rhine. In 1758, the Duke of Belleisle was placed at the head of the military department in France; and the ministers, who had obtained their situations through female influence, were dismissed. The Duke soon discovered how fit he was for the arduous task that he had undertaken. His first object was to strengthen the army on the Rhine; but, notwithstanding this, it was defeated at Crevelt by Prince Ferdinand, and obliged to retire under the cannon of Cologne. In this battle, the son of the Duke of Belleisle was killed,—a young man of great promise, and whose fate was equally lamented by his enemies and his own countrymen. Further reinforcements being sent to the French army, and M. de Coytades having assumed the command, Prince Ferdinand was obliged to act on the defensive for some time: he afterwards joined the British forces, and put his army into winter quarters towards the end of October.

Naval affairs of 1758 belong more properly to the History of Britain: nevertheless, it may be proper very briefly to notice them here. Two French ships of the line were driven on the coast of Spain by Admiral Osborne. The same fate attended a fleet that was bound for North America. But the success of Britain against France, in other respects, was not so great as her naval supremacy led the inhabitants of the former country to expect, and of the latter to dread; for an expedition prepared at considerable expense, and from which great expectations were formed, to the coast of France, by no means produced the triumph to Britain, or the loss and degradation to her enemy, which was anticipated. Cherbourg, indeed, was taken, and the fortifications demolished; but, in consequence of the accumulating force which the French collected, it was then deemed necessary to retreat; and at St. Cas the retreating army suffered severely.

In America, where the war may be said to have originated, the French were unsuccessful. Louisburg was besieged and taken; and the whole island of Cape Breton, as well as that of St. John, submitted to the arms of his Britannic Majesty. The French settlements on the river Seagul, and the island of Gorce, were also wrested from them. In the East Indies, however, the Count de Lally, governor-general of their possessions there, was more fortunate, having taken possession of the British factories of Cuddalore and Fort St. David.

In the beginning of 1759, the French made themselves masters, by an act of perfidy, of Frankfort on the Mayne. As this acquisition secured to them the course of the Main and the Upper Rhine, the allies resolved to attempt their dislodgment; but Prince Ferdinand, in attempting to gain possession of the village of Berge, which was necessary for this purpose, was repulsed by the Duke of Broglio. Soon afterwards, the French armies on the Upper and Lower Rhine formed a junction, which rendered it prudent for the Prince to retire. Nothing now intervened to prevent them from taking possession of Munster and Minden; and the acquisition of them exposed Hanover to great danger. The Prince, therefore, in order to save the electorate, resolved to give them battle; and the battle of Minden was fought, in consequence, on the 1st of August. Although the result of this battle was, perhaps, not so satisfactory and advantageous to the Prince as it might have been, it enabled him to defend the electorate effectually. No other event of consequence having taken place this year on the Continent of Europe, in which the French were concerned, we shall now briefly notice the disasters that attended them in the West Indies, North America, the East Indies, and by sea. In the West Indies, Guadaloupe was reduced, though they saved Martinique from the attack of the English. In North America, the genius and gallantry of Wolfe stripped them of all their possessions, by the victory which he gained on the heights of Abraham. In the East Indies, General Lally was at first successful; he even attempted the siege of Madras, but he was obliged to abandon the enterprise. The French were afterwards defeated with great slaughter in two engagements. By sea they were more than usually unfortunate this year; for, making preparations for an invasion of Britain, all their ports in the Channel were blocked up by Admirals Rodney and Hawke; while Admiral Boscawen, for a time, succeeded in blocking up their fleet in the harbour of Toulon. The French Admiral, however, found an opportunity to escape; and the sea-fight off Cape Logos was the consequence, in which the Toulon fleet was defeated, with the loss of four ships of the line. Notwithstanding these disasters, the French minister seemed still bent on invading England; and the English fleet having been driven off the coast of France in a storm, Admiral Conflans put to sea with 21 sail of the line and some frigates; He was met by Admiral Hawke, and defeated with great loss, between Belleisle and Cape Quiqneron.

In order to compensate for these losses, the French government resolved to open the campaign of 1760 in Europe with immense force; and as the nobility and gentry seconded the exertions of the government, it was enabled to augment the army in Westphalia, under Marshal Broglio, to 100,000. The allied army under Prince Ferdinand, though less numerous, was better appointed. Nothing of importance occurred between them till the 31st of July, when the French were defeated at the battle of Warburg, and obliged to retreat with the loss of 3000 men. In consequence of this victory, Prince Ferdinand was enabled to protect Hanover; but the dominions of the Landgrave of Hesse were still exposed to the French. Soon afterwards both armies went into winter quarters. In the East Indies the French were stripped of nearly all their possessions this year.

The death of George II. led the French government to hope that his successor might be disposed to relax in his efforts to support the continental war; but as soon as they were convinced, from the liberal supplies voted by the British parliament for the support of the German confederacy, that their expectations were ill founded, they, in conjunction with the court of Vienna, proposed terms of peace. A congress was accordingly appointed to be held at Augsburg for the continental powers; while the separate discussions between Britain and France were to take place at Paris and London. Notwithstanding these negotiations, hostilities were still carried on; and, with respect to the particular
FRANCE.

Dispute between France and England, it was soon evident, that it was more likely to be extended than adjusted, in consequence of the disposition which the court of Madrid displayed to unite with France. The principal scene of the French military operations was Westphalia, where at first they were successful, obliging Prince Ferdinand to retire behind the Dyemel; but that indefatigable general soon afterwards repulsed the united forces of Broglio and Soubree, and thus was enabled to effect his grand object, the protection of Hanover. Still, however, the campaign was as indecisive, with regard to permanent or extensive advantage on either side, as any of the former campaigns had been; and it was evident, that such operations would exhaust the resources both of the French and the allies. As the British ministry felt their peculiar strength to consist in the command which they now possessed of the sea, they planned another expedition against the coast of France, which effected the reduction of Belleisle. This, no doubt, was a great mortification to France, but it did not induce her to weaken her Westphalian army; and therefore, as a diversion in favour of Prince Ferdinand, it totally failed, while it was impossible for the British to retain their conquest. The negociations were now again resumed; but as the offers of cessions and exchanges made by the court of Versailles did not meet the expectations of the British cabinet, they were finally broken off. The cause of this failure was soon traced to the court of Madrid, between which and the court of Versailles a family compact had been some time before entered into. According to this compact, the Kings of France and Spain were to have common enemies and friends; so that war declared against one was to be regarded as war declared against both; and consequently, on such an event happening, the whole military forces of both were to act in the most perfect concert. No peace was to be made except by mutual consent. Spain, however, was not to succour France when she might be involved in a war in consequence of her engagements by the treaty of Westphalia, or her other alliances in Germany or the north, unless some maritime power took part in those wars, or France itself were attacked. Between the accession of Spain to the cause of France in her war with Britain, and the peace of Paris, no event of importance occurred, except the reduction of the island of Martinique by a British armament.

In consequence of a change of the British ministry, France found that a peace was more practicable than formerly, while she herself, as well as Spain, were more sincerely disposed towards it: negociations, therefore, were carried on at Fontainebleau, and on the third of November 1768, the preliminaries were signed there. On the 16th of February, in the following year, the definitive treaty was signed at Paris. By this treaty France agreed to cede to Britain, Canada, in its utmost extent, with the islands of Cape Breton and St. John, and all that part of Louisiana which lies on the side of the Mississippi, except the town and territory of New Orleans. The French were permitted to fish, under certain limitations, on the banks of Newfoundland: the islands of Martinique, Guadeloupe, St. Lucia, Gorce, and Belflise, were restored to them; and the French East India Company were placed in the same situation in which they were at the peace of Aix-la-Chapelle, by the restitution of Pondicherry, &c.; but they were not to erect any forts in the Province of Bengal. France agreed to cede to Great Britain the forts and factories she had lost on the river Senegal, the island of Grenada and its dependencies, and to give up all claim to the neutral islands of St. Vincent, Dominica, and Tobago; she also consented to destroy the harbour and demolish the fortifications of Dunkirk.

France had much need of repose; for, not only were her finances in a very dilapidated condition, but disputes between the King and the parliaments agitated the minds of all; these disputes had been already noticed. And as the parliaments felt their own power and importance, while the King became sensible of the necessity of curbing them, they every day became more serious. The parliament of Paris refused to register several of the royal edicts; and the parliament of Brittany, determined to manifest that they also were adverse to the King, refused the crown a gift of 700,000 livres, in consequence of which they were dissolved. But Louis, afraid of creating still greater disturbances, published a general amnesty, and wished them to resume their functions. The parliament, however, convinced by this that the King was intimidated, and their cause was popular, refused to accept his proffered clemency. The indignation of the King was now extreme; and he ordered such of the councillors of the parliament of Brittany as had refused to resume their functions, to be included in the list of those who were to be drafted for the militia; and such as were drafted were actually obliged to join their regiments, while the rest were incorporated in the city guard. The severity of this conduct appeased the stubborn spirits of the parliaments for some time; but the calm was not of long duration. In the midst of these convulsions, which extended to nearly all the parliaments in France, the Dauphin died, in the 37th year of his age; and the Duke of Berri, his eldest son by his second marriage with Maria Josepha of Saxony, was created Dauphin in his stead.

As soon as Louis had in some measure quieted the Corsica an-parliament, he turned his attention to the acquisition of the island of Corsica. This island had for some time resisted the tyranny of Genoa, which claimed the sovereignty by right of conquest: At last the Republic, unable to support her pretensions, transferred them to France, on condition that Louis should put her in possession of the island of Capraria, which the Corsicans had lately reduced. Louis thought that the subjection of the Corsicans would be easily and speedily effected; but he found himself much mistaken, as the Corsicans defended themselves with great intrepidity; and two campaigns, with the loss of several thousand men, were necessary to bring them under the power of France.

The finances of the country were at this period, A.D. 1768, 1769, very inadequate for the support even of such a trifling war as that in Corsica. The East India Company were absolutely bankrupts; numbers of the most respectable merchants were exposed to every species of failure and distress. Such a state of things required the measures of a man of talents and experience; whereas the Duke of Choiseul, who was minister, was neither, and by attempting to remedy, he actually increased the evil: he reduced, at once, the interest of the public funds one half; and, as if this were not sufficient to injure public credit, he took away the benefit of survivorship in the tontines. The king at last was under the necessity of banishing him; but, instead of remedying
the evils by the restoration of public credit and confidence, and by calling in to his assistance the advice and authority of the parliaments, Louis again involved himself in disputes with them. As he had no idea of carrying his measures calmly, he resolved to banish the parliament of Paris, which had given the tone to the others; and, soon after this was done, several of the provincial parliaments were dissolved. It was necessary, however, to appoint new parliaments; and though the people did not view them with their accustomed respect, the King received from them unlimited obedience.

In the midst of these disputes, which would scarcely be worthy of notice did they not point out the causes of the Revolution, the Dauphin was married to Maria Antoniette, sister to the Emperor of Germany. At the splendid entertainment and shows given on this occasion, a dreadful accident happened; the crowd hastening to be the spectators of the fireworks, pressed on one another in such a tumultuous manner, that several hundreds perished in the confusion.

As soon as Louis had freed himself from the opposition of his parliaments; he gave himself up completely to debauchery; but his health was not equal to the inroads made upon it; and his satiated appetite required the constant stimulus of new beauty, and a succession of mistresses. One of these, who was infected with the small-pox, communicated the disorder to the king. The danger hourly increased; and Louis, apprised of his approaching dissolution, fondly hoped to atone for his past debaucheries, by his present penitence: He received the sacrament; and declared his intention, if he should survive, of exerting himself in the cause of religion, and for the benefit of his subjects; but in eight days after the first attack, he closed his reign of 59 years, and a life of 65.

This monarch had nothing to recommend him to the affection or gratitude of his people, though, at the beginning of his reign, in the moment of danger, the appellation of well-beloved had been conferred upon him. Thirty years of rapacity, profusion, and tyranny, as a monarch, and of the most profligate debauchery in his private life, had, however, induced the people to retract that appellation. His example loosened the bands of morality; the credit and resources of the country had been nearly exhausted by his prodigality; what remained of a free constitution in France had been crushed, as far as he could crush it, by his tyrannical measures. He does not seem to have been capable of any generous feeling; his affections were confined within the narrow limits of his personal pleasures and security; whoever could administer the one, or accomplish the other, was with him a favourite; but as soon as they ceased to be useful in these respects, they were neglected and forgotten. Even the Marchioness of Pompadour, who had so long enjoyed his confidence and shared his embrace, expired, without drawing a single sigh of regret or affection from the breast of Louis, though, during her life, he had obeyed and adored her; and to the death of the Dauphin he was equally insensible. Even his exertions against the parliaments would not have been made, though his principles and feelings were sufficiently arbitrary to have led him to have wished their abolition, had not his indolence been goaded on by the stimulating representations of the Countess du Barri, that while they existed he year 1774, he succeeded to his grandfather. One of his first measures was, to remove those from office, who, by their errors or misconduct, had become unpopular, and had contributed to the distresses of the kingdom; and to replace them by men of talents and honesty. He likewise gave great satisfaction, by suppressing the new, and recalling the ancient parliament of Paris, though, at the same time, he limited their privileges, and declared his intention not to submit to any power in them, which could possibly circumscribe his own. Scarcely were the members returned, however, before they displayed their spirit and pretensions; but Louis, in answer to one of their representations, peremptorily declared that he must be obeyed.

The state of the finances was still such as to require great care in their management, and in their restoration. For this purpose, the celebrated Turgot was placed at their head in the year 1775. His measures, in some respects, were undoubtedly wise and salutary; but, in other respects, he seems to have suffered speculative opinions too much to influence him. Even his wisest plan, that of rendering the internal commerce of grain, as well as its exportation, free and unrestricted, gave rise to serious disturbances, in consequence of a scarcity of corn happening at the very time of his regulations. The tranquility of the country, as well as of Paris, was so much disturbed, that Louis found it absolutely necessary to have recourse to very strong measures; and the Marechausse, a military body dependant on the police, were ordered to disperse the multitude, and to execute summary justice on the most guilty. After the suppression of these disorders, Louis, in order to draw off the minds of his subjects from the unpleasant recollection of them, and of the harsh means by which they had been quelled, resolved to celebrate his coronation with great magnificence at Rheims; and, to prove that the measures he had lately been compelled to adopt were not the result of a cruel or tyrannical disposition, he issued an edict, which in future sentenced deserters to work as slaves on the public roads, instead of punishing them, as formerly, with death. He also suppressed the mousquetaires, and reduced part of the regular army. By the former measure, he relieved the citizens of Paris from an impetuous and overbearing body of men, the suppression of whom no former sovereign had ventured to effect; and, by the latter measure, he gave gratifying testimony to the nation at large, that he was resolved to introduce the strictest economy.

Still, however, the situation of the world rendered it prudent for Louis to direct his thoughts to the not improbable renewal of hostilities. Great Britain was at this time involved in serious disputes with her colonies. France, however disposed to remain at peace, on account of the state of her finances, was too interested in the humiliation of Britain, not to regard with satisfaction the progress of a dispute, which might afford her a fair opportunity of weakening her ancient rival. This would be best effected by being able to meet that rival on her own element. The navy of France was therefore an object of great interest; and the appointment of Monsieur Sartirne to the superintendence of the marine, did honour to the penetration of Louis. He was fruitful in his resources, and unwearied in his application; and in a short time, the losses of the last war were nearly supplied.

But the finances were not so easily managed. Turgot, not possessing the public confidence, had resigned, and...
Necker was soon afterwards placed at their head. In order that he might carry into full and uncontrolled effect all his plans, the entire management of the funds and revenue of France was submitted to him, with the title of director-general of the finances.

The interests of science next engaged the attention of Louis and his ministers. Several vessels were fitted out on astronomical discoveries. The Chevalier de Borda was instructed to ascertain the exact position of the Canary Islands and the Cape de Verdi, and the different degrees of the coast of Africa, from Cape Spartel to the island of Goree. The Chevalier Grenier, who had traversed the Indian ocean, for the purpose of improving the charts, and correcting the errors which had misled former navigators, was liberally rewarded.

In proportion as the success of the Americans increased the probability that they would ultimately establish their independence, the French cabinet, as well as the French nobility, were desirous of uniting with them, and thus contributing to the humiliation of Britain. But the former concealed their wishes and their resolutions, and even restrained the ardour of the latter, till a proper opportunity offered itself of openly taking part with the Americans. As soon as the measures of Great Britain had caused the people of her colonies to the daring resolution of rising against their mother country, Silas Deane and Dr Franklin were sent to Paris. Here they exerted secretly their influence with the leading men in the French cabinet; and though, in a public capacity, they were not admitted to an audience, yet they received sufficient encouragement to hope, that, before long, their country would be assisted by the arms of France. In the mean time, the American privateers were allowed to rest in the French ports, and even to bring their prizes into them. Warlike stores were sold or given to the colonists; French officers and engineers, with the connivance of government, entered into their service; and the Marquis de la Fayette, a young nobleman of affluent fortune and high birth, sailed for America, where he was received with open arms, and appointed to a principal command. These circumstances naturally excited the suspicions of the British court; but, as nothing was done openly, they had no sufficient ground for remonstrating, till warlike preparations were carried on in such an undisguised manner, and to such an extent, as could leave no doubt that France was on the eve of hostilities with some power. Upon this, the English ambassador at Paris closely questioned the French minister, who replied, that when the seas were covered with English and American ships of war, and when large armies were sent to the New World, it became prudent for France to arm for the defence of her colonies, and the protection of her commerce. The outward forms and the language of neutrality, were, however, preserved, till the capture of General Burgoyne and his army, when they were at once dismissed from the French cabinet, and the independence of the United States of America was openly acknowledged. Silas Deane and Dr Franklin were received as public ambassadors, and a treaty of amity and commerce was signed in the month of February 1778. The recall of the English ambassador from Paris was the signal for the commencement of hosilities. The details of this war between Britain and France having been already given in our article "France," we shall confine ourselves to the domestic transactions of France.

Monsieur Necker still continued at the head of the finances, and endeavoured to render the pressure of the war as light as possible, by plans of economy and retrenchment; a variety of unnecessary offices in the household of the King and Queen were abolished, and other important regulations adopted for the benefit of the kingdom. At the same time, the diplomatic skill, experience, and intrigues, of the different French ambassadors at the courts of Europe, were successfully exercised in rousing them, either directly or indirectly, to take advantage of the present circumstances, and crush, or at least weaken, the naval power of Britain. As a long and intimate connection had subsisted between the courts of Petersburgh and London, the French ambassador at the former was instructed to conciliate the inclinations of the Empress; and he conducted himself with so much adroitness, as to be very instrumental in persuading her to place herself at the head of the Northern Confederacy. In answer to the declaration which she addressed to the courts of Madrid, Paris, and London, on the subject of neutral rights, the King of France declared, that what her Imperial Majesty claimed from the belligerent powers exactly corresponded to the rules prescribed to the French navy; and as he was convinced solid advantages would undoubtedly result, not only to her subjects, but also to all nations, she might depend that he would adhere to his usual practice, and comply with her wishes. Towards the close of the year 1780, Monsieur Sartine was removed from the marine department, which he had superintended for five years. His great and leading object had been, during the whole of this time, to place the French navy upon the most extensive and efficient footing; and he had succeeded in raising her naval power to an unprecedented height; but his measures for this purpose necessarily required the expenditure of very large sums of money, at a time when the state of the finances loudly called for economy and retrenchment. Hence his measures and wishes were at variance with those of the comptroller-general of the finances; and his removal was the consequence. He was succeeded by the Marquis de Castries.

The disposition of Louis, naturally humane, was most honourably displayed this year, by the abolition of the practice of putting the question by torture: and his desire to relieve his subjects as much as possible from the pressure of the taxes, was evinced by the further diminution of his own expenditure, and by his dismissing at once 406 officers belonging to his court. In this adherence to a system of economy so unusual in the sovereigns of France, Louis was undoubtedly strengthened by the advice, and perhaps the remonstrances, of Necker. This minister continued to be uncommonly active and faithful in the discharge of the duties of his important and arduous situation; but he was rather a man of detail than of general principles or comprehensive mind; and he did not always perceive the necessity or advantage of accommodating his plans, in some degree, to the habits and prejudices of the French nation. He conceived the impracticable idea of maintaining the war by loans, without additional taxes; not reflecting that loans cannot be raised in any country, in which there is not only a great superabundance of capital, but also the most implicit confidence in the faith of government. Unfortunately for his scheme, capital was far from being abundant in France, and the measures of former sovereigns, as well as the nature of the government, were by no means calculated to inspire confidence.
There were besides other causes, which shook the popularity of Necker; his temper was austere and unaccommodating; the reforms and retrenchments which he had introduced into the various departments of the royal household, were represented as derogatory to the dignity and splendour of the crown; and his foreign birth and mercantile education and habits, increased the jealousy and dislike created by his temper and plans of economy. The King for some time endeavoured to oppose his favour and countenance to the intrigues that were formed against him; but at length, towards the close of 1781, he was dismissed from his office of comptroller-general, and Monsieur de Joli Fleurie succeeded him.

The people at large beheld this change with regret, which was by no means diminished when the new comptroller-general reverted to the old plan of raising taxes. It was, however, soon ascertained, that the burdens of the nation could not be much more augmented; and the ministry, in order to multiply the resources of government, without pushing taxation to a dangerous extent, endeavoured to kindle in Paris, and throughout the provinces, such a degree of enthusiasm as would produce voluntary contributions towards carrying on the war. Their efforts were seconded by the consternation and feeling of humiliated pride, which the defeat of Count de Grasse produced throughout the kingdom; and several states displayed their zeal in building and fitting out ships of war, to repair the loss which had been occasioned by this defeat. The clergy also came forward at this time, with a free gift of 15,000,000 of livres towards the exigencies of the state; and they also offered another million to be applied to the support of wounded seamen, and of the widows and orphans of those who had been killed in the various naval engagements.

About this period, the attention of the French ministry was directed to the commotions that agitated the republic of Geneva. These commotions arose from the magistrates and senate having increased their own authority, and diminished the privileges of the people: the latter were still farther irrate by the additional taxes which were imposed upon them; and, at length, their leaders insisted on having a regular code of laws, which might prescribe the authority of the rulers, and sanction the rights of the people. The aristocracy objected to this; and in their own support called for the interference of foreign powers. The King of France, as protector of the republic, concerted, with the King of Sardinia, and the cantons of Zurich and Berne, such measures as they thought would restore tranquillity to it; and in order to give weight to these measures, an army of 12,000 men was encamped under the walls of the city. Thus protected, the magistrates gained a complete ascendency over the people; but they afterwards, during the French Revolution, had too good reason to repent having called in the interference of France, thus virtually acknowledging a dependence on that power, which was not forgotten.

Although the preparations for war in 1783 were very great, yet Louis was disposed for peace, and therefore accepted the mediation of the Emperor of Germany and the Empress of Russia. This mediation was successful, and a treaty of peace with Great Britain was concluded on the 20th of January. By this treaty, France acquired an additional extent of fishery off Newfoundland. In the West Indies, she regained St Lucia and Tobago, but relinquished Grenada, St Vincent, Dominica, St Christopher's, Nevis, and Montserrat. In Africa, she acquired the full sovereignty of the forts on the Senegal, and regained Goree; while she guaranteed to Britain, Fort St James's, and the river Gambia. In the East Indies, all that she had lost was restored, and some additions were made to her former possessions. But the most gratifying article of this treaty to the national glory of France, was, that the fortifications of Dunkirk were no longer to be forbidden,—the stipulations exacted from Louis XIV. and XV. respecting them being formally abolished by the peace of Paris.

The joy created in France by the termination of a war, in which she had been so eminently successful in weakening Great Britain, was not of long duration. The state of her finances grew daily worse. Three different successors of Monsieur Necker had in vain attempted to remedy or palliate the evil; public credit, as well as the public resources, were too nearly exhausted to be revived. Government refused, or delayed the payment of the bills drawn upon them by their army in America; and nearly at the same time the Caisse d'Escompte stopt payment. This last circumstance created general and excessive alarm. Their notes having been hitherto always convertible into specie at the option of the holders, had circulated very widely; and as they were not out to individuals at this period to a larger amount than usual, or than their known capital authorised, the suspicion was created that they had, to the prejudice of the holders of their notes, and contrary to their own interest, as well as that of the public at large, accommodated government with the specie, which ought to have been exclusively devoted to the payment of their notes. It now became absolutely necessary for government to interfere, in order, by supporting this bank, to restore the confidence of the public in it. Four edicts, therefore, were issued with this view: by these, the banks of Paris were ordered to receive the notes of the Caisse d'Escompte as currency; and a lottery, with a stock of one million sterling, was established, redeemable in eight years, the tickets for which might be purchased in the depreciated notes. At the same time, government having procured money, paid their American bills. Public credit was thus restored; and the stock of the Caisse d'Escompte rose considerably above its original subscription.

The comparison between the measures adopted in England, when its national bank declared their inability to pay in cash, and those adopted in France on the present occasion, cannot fail to strike the reader. In the former country, all that was absolutely necessary for the support of the bank was accomplished by individuals; in the latter, it was the exclusive work of the government. In the former country, a temporary alarm had shaken public credit; but the wealth and real confidence of the nation remaining the same, as soon as that alarm subsided, public credit was again placed on as solid a foundation as before: whereas, in France, the shock given to public credit arose from permanent causes, and the measures adopted only palliated, or put off the evil.

The state of the finances of France, thus artificially kept from falling into utter ruin, absolutely required the most rigid and systematic economy: indeed, no other means could restore them even to temporary strength; and yet, not only were the forces not reduced, but all the deficiencies in the different regiments were made good. At this period, there could exist no alarm or pro-
bility of renewed hostilities, though, shortly afterwards, the disputes between the Emperor and the United Provinces, respecting the barriers and strong towns in the Netherlands, excited the attention and jealousy of France. Before the late war, a French faction had scarcely existed, or, at least, had not been powerful in Holland; but that event, by detaching Great Britain from the United Provinces, had opened up an opportunity for such a faction to establish itself at the head. This faction consisted of the hereditary enemies of the Orange family; so that in Holland, as in America, the despotic government of France united itself with republicans. As soon as the Emperor extended his pretensions to the navigation of the Scheldt, the Dutch implored the mediation of the King of France, their late hostility with Britain having deprived them of any claim for protection or mediation from that power. At this time, there were two parties at the court of Versailles, at the head of which were the Count de Vergennes and the Marshal de Castries; the former, the favourite of Louis, was, like him, mild, humane, and a strong friend to peace; the latter, supported by the Queen, was, like her, bold, intriguing, and enterprising, and the strong advocate for war. As the mediation of France had no influence with the Emperor, and the Dutch saw themselves threatened with hostilities, in consequence of having opposed his designs on the Scheldt, they applied to Louis for a general to head their armies; and the Count de Mlleibois was sent to them. Count de Vergennes, hitherto, had opposed any hostile or violent measures; but, at this juncture, in consequence of the encroaching aggressions of the Emperor, he expostulated with the court of Vienna in more free and direct language. At the same time, the armies of France moved by degrees to the borders of Alsace, Lorraine, and the Low Countries; and orders were given to form a camp at Luns of 80,000 men. The Queen of France, though ambitious and warlike, by no means approved of these indications of hostile measures against her brother the Emperor; and therefore endeavoured to bring back the mind of the Count de Vergennes to its habitual feeling of moderation and love of peace; but the Count, though sensible of the state of the finances of France, and therefore desirous, if possible, of averting hostilities, could not brook the idea, that the honour or interests of his country should be sacrificed; and, on the morning when a grand council was to be held, the result of which was to be conclusive with regard to the part France should take, and the Queen desired he would not on that day forget that the Emperor was her brother, he replied, that he certainly would not forget, but he must also remember that the King of France was her husband, and the Dauphin her son. Soon afterwards, the Emperor accommodated his differences with Holland, through the mediation of France, and thus the military preparations of the latter were rendered unnecessary.

The influence of France at the Hague, was thus considerably strengthened; and the Count de Vergennes did not fail to make use of it for the advantages of his country, by forming a new treaty of alliance. By this treaty, in case Holland was engaged in war, France was to furnish her with 10,000 infantry, 2000 cavalry; 12 ships of the line, and six frigates; and, in the event of a maritime war, or, in other words, in case England and France should recommence hostilities, the United Provinces engaged themselves to furnish six ships of the line, and three frigates. If France were attacked by land, they were either to furnish 5000 infantry and 1000 cavalry, or a proportionate sum of money.

The internal condition of France was every day becoming more alarming. Monsieur de Calonne was now at the head of her finances. He had already displayed address and talents in the measures that he suggested for the re-establishment of the Caisse d'Amortissement. He also established the Caisse D'Amortissement, or sinking fund, the plan of which was recommended by its simplicity. According to it, government were to pay annually into the hands of commissioners, the entire interest of the national debt, together with an additional sum of £120,000 sterling. By this, it was estimated that annuities to the amount of £50,000 would be annually extinguished; and in that proportion the sum set apart for the liquidation of the national debt would be increased. In order to secure, as it was expected, the regular application of this sum, the annual receipt of the Caisse D'Amortissement was declared incapable of being diverted to any other object. But it is manifest, that, in a country where the regular expences of the state were far above its income, it would be impossible to raise the additional annual sum requisite for the establishment and operation of a sinking fund. The object of the financiers of France ought to have been exclusively to relieve the existing difficulties, and not by any means to have extended their views and plans to a remote generation. There were besides other causes operating against the success of any plans of finance, which will unfold themselves as we proceed in the history. As the manners and the talents of Calonne were more insinuating and popular than those of Necker, while he was also more accommodating to the necessities or the wishes of the court, he was their favourite; but with the nation at large, he was not so great a favourite as Necker had been. He continued, however, to support himself without being exposed to any considerable degree of odium, till the year 1785, when, by the establishment of a new East India Company, he excited violent censure. The objections urged against this monopoly were brought forward in a style of boldness and freedom, hitherto unusual in France; and, from the substance as well as the manner of them, it was evident that those philosophers who had hitherto confined their speculations on government and political economy to books, were extremely desirous of reducing them to practice. Monsieur de Calonne was by no means in a condition to regard the discussions which this subject gave rise to with indifference; as they plainly indicated, that a body of men who at this time had great influence in France, were decidedly hostile to the measures of his administration. He likewise was convinced, that the re-establishment of the finances was a much more arduous task than he had anticipated; for though France had now been at peace for three years, it was found requisite at the end of each year to supply the deficiency of the revenue by a loan. Still, however, had the rigid economy recommended and pursued by Necker been persevered in, the expenditure and the income might have been brought more nearly on a level; but large sums were laid out on the fortifications of Cherbourg; and the Marquis de Castries, as minister of the marine, had been profuse in his expenditure. These sums might have been saved, as there was no absolute and pressing necessity either to extend the fortifications of Cherbourg, or to increase the navy. The money required during the dispute between the Emperor and the
Dutch, for the purpose of placing the French army on a respectable and efficient footing, was more properly laid out.

As the internal resources of France were the only means by which the revenue could be augmented, it became the paramount duty of the ministry, to nourish them with the greatest care and attention. That they did not perform this duty in a conscientious and wise manner, was loudly and generally urged against them, in consequence of the commercial treaty between Great Britain and France in the year 1786. On this subject, strong and unfounded prejudice bore down calm and clear investigation; but, in some respects, it must be admitted, that the framers of the treaty did not sufficiently advert to the protection which the weak and infant manufactures of France required, in order to enable them to rise to an equality with those in England, or, at least, to meet the English manufactures in the markets of France.

The popular mind was now in such a state of discontent and irritation, that the smallest evil made it break out into bitter complaints against government. It may therefore well be conceived, that the edict at the end of the year 1785, for registering a loan of the enormous amount of £3,333,000 sterling, produced violent murmurs. When this edict was presented to the parliament of Paris, they selected a deputation to wait on the King in their behalf, with the information, that he expected to be instantly and implicitly obeyed; and the ceremony of registering took place the next day, accompanied, however, with a resolution, that public economy was the only genuine source of abundant revenue, and that without it, the necessities of the state could not be supplied, nor public credit and confidence restored. This firmness was highly displeasing to the King; he ordered the records of the parliament to be brought to him, and erased the resolution with his own hand; at the same time declaring, that he expected in future they would communicate, in a loyal and respectful manner, whatever they deemed advantageous to the nation. As the parliament were at variance with Calonne, the King embraced this opportunity of supporting the measures of that minister, which were not to be defeated by their violence or groundless apprehensions. In order more strongly to mark the royal displeasure, one of the members, who had been most active in passing the resolution, was dismissed.

Calonne at this period seems to have been first convinced of the necessity of assembling the Notables. It is probable, that he expected from them a more ready acquiescence in his views and plans than he had met with from the parliament of Paris; and as these views and plans now went far beyond the measures he had at first proposed and adopted, it was proper they should be sanctioned by a body more numerous, as well as more respectable, than the parliament. He was convinced that the state of the kingdom was such, both with respect to its finances and resources, and with respect to the general feeling of the necessity of some political reform, that farther delay would be dangerous; and he hoped that the assembling of the Notables would remedy the existing evils in the most safe and legitimate mode. He had, indeed, the option of assembling either the States-general or the Notables. The former had not been called together since the year 1614: They consisted of deputies chosen by the three estates, the nobility, clergy, and people at large. To this assembly Calonne had strong objections: In the first place, the election of the deputies, in the agitated state of the country, could not fail to increase the commotion, and to let the people feel too sensibly their own weight and influence; in the second place, the deliberations of such an assembly would necessarily be tedious and, consequently, the distracted state of the country would be prolonged. But the circumstance which weighed with the minister most powerfully against calling out the States-general, was the apprehension that they would be disposed to carry the reform much farther than he wished; and the impossibility of foreseeing what would be the consequence of putting power into their hands. The Notables, therefore, an assembly which had been occasionally substituted in the room of the States-general, was preferred by Calonne. It consisted of a number of persons from all parts of the kingdom, chiefly selected from the higher orders of the state by the King himself. This mode of selection would render the delegation of power to them perfectly safe, it was expected; while their deliberations would be shorter, and more easily managed by royal influence. The writs for calling together this assembly were accordingly issued on the 20th of December 1766: they were addressed to seven princes of the blood, nine dukes and peers of France, eight field marshals, twenty-two nobles, eight councillors of state, four masters of requests, seven archbishops and bishops, thirty-seven heads of the law, twelve deputies of the 'pour d'etat, the lieutenants-civil, and twenty-five magistrates of the different towns in France. The total number was 144; and the opening of the assembly was fixed for the 29th of January 1787.

It ought to have been the leading object of the minister, to have laid before this assembly his plans as soon as possible, and immediately after their sanction of them to have dismissed them. This, at any period, would have been the wisest method; but it was more particularly required at a time when Paris was filled with discussions on points that went far beyond the mere re-establishment of the finances, or the reform of acknowledged and gross abuses. When the day of meeting came, however, the minister was not prepared; it was therefore put off till the 7th of February; but, before this day arrived, Calonne fell sick, and the Count de Vergennes died. The loss of this statesman was severely felt by his colleague, as he had entered fully and warmly into all his plans, whereas the keeper of the seals was his avowed enemy, and the minister of the marine department was personally attached to Necker. The secretary for the household was the creature of the Queen, and, consequently, attached to what was called the Austrian system. At length, on the 22d of February, the first meeting of the assembly of the Notables took place. Calonne laid before it his plan for re-establishing the finances and the public credit of the kingdom, which he proposed, by pointing out the necessity of adopting it, or some other. He stated, that when he was appointed to the office of comptroller-general of the finances, the deficiency of the public revenue amounted to £3,330,000 sterling. This, it was evident, must be made up, as well as prevented in future, if the finances of the country were to be restored to a proper state. For this purpose he proposed, that a territorial impost, from which no class or order of men should be exempted, should be sanctioned by the assembly; that the clergy, hitherto not considered liable to pay taxes, should contribute in a fair proportion to the exigencies of the state; that the management and receipt of the taxes already existing, should be the subject of minute
impartial, and strict investigation; and that, if these measures were not adequate to the cure of the evil, the demesne lands of the crown should be mortgaged.

If the minister expected that his statement and his plans would be implicitly received by the assembly, or that they would, at the most, only give rise to such a kind of discussion as would preserve the appearance of independent authority in its members, while it did not essentially oppose the minister, he was most grievously mistaken. He had represented the resources of France as very contracted, and her debt as large; and on these grounds he had called upon the assembly to sanction his plans: But before Necker had retired from the management of the finances, he had published a work, in which he represented France as possessing a surplus revenue of £425,000. It was not to be expected, that the gloomy statements of Calonne would not be contrasted with the cheering statements of his predecessor. Before, therefore, the members of the assembly proceeded to discuss the plan it-self, they insisted, that there was no necessity for its adoption; and that, if the ministers were honest and able, France might easily, without any sacrifice or additional burden, be extricated out of her present difficulties. These attacks on the ability and honesty of Calonne, were supported principally by the Archbishop of Toulouse and the Count de Mirabeau; the latter a man of brilliant talents, of the most progitate principles and conduct, and who was resolved, that his country should, if he could possibly effect it, be plunged into such a state of anarchy, as would give room for the exercise of his talents, and the unrestrained play of his most vicious and dangerous habits.

The minister soon found, that his plan met the approbation neither of the nobility and clergy, nor of the people at large. The ancient nobility and clergy had hitherto been free from taxes; and, as patents of nobility were easily procured, they were eagerly sought after, for the purpose of exempting the possessors from taxation. The nobles, therefore, both old and new, were strongly averse to a plan which should oblige them to contribute to the exigencies of the state; and they were supported in their opposition by the clergy and the magistrates, who also were exempt from taxation. It might, however, have been expected, that the mass of the people would have regarded Calonne as their friend; since, if his plan was carried into effect, they would be relieved from part of their burden. But at this period the people had no means of making their feelings or wishes known; and besides, the measures of the minister, in other respects, had not been such as to command or deserve popular favour and support. He was therefore assailed, unprotected, by the nobility, clergy, and magistrates, who were so blinded by an imperfect and selfish consideration of their own immediate interest, as to refuse to restore public confidence and tranquillity by a trifling sacrifice. In the month of April, Calonne, finding it impossible to maintain his ground, resigned his office, and retired to England.

In the year 1787, the disputes in the United Provinces between the republican party and the Prince of Orange, again opened an opportunity for the cabinet of Versailles to strengthen its interest in Holland; and had not the King of Prussia taken a decided part in support of the Prince of Orange, it is probable that the republicans, aided by the French, would have borne down all opposition. The cabinet of Versailles, however, did not deem it prudent so assist them in an open manner, though they permitted their officers to go into Holland, and even sent tried and experienced soldiers for the purpose of disciplining theburglars and volunteers. Great Britain also, forgetting the conduct of the United Provinces during the American war, or rather, perhaps, ascribing that conduct to the influence of that party which was now endeavouring to destroy the authority of the Stadtholder, fitted out a squadron of men of war, for the purpose of countenancing and supporting the measures of the King of Prussia. Upon this, the French ministry also began to equip sixteen sail of the line at Brest, and recalled a small fleet of men of war which were cruising off Portugal. It was very evident, that a mutual jealousy between the courts of Versailles and St James's had no small influence in giving rise to these hostile indications; but as soon as the power of the Stadtholder was re-established, and, of course, all pretences for armaments taken away both from Britain and France, each cabinet was anxious to replace things on their former footing. Britain had begun to feel the beneficial consequences of Mr Pitt's measures of finance, and of her reviving commerce; and France felt too sensibly her inability to plunge herself into a new war, if it could possibly be avoided. The navies of both nations, therefore, were placed on the footing of a peace establishment, and harmony was restored between them.

From these momentary and comparatively trifling subjects of uneasiness, the mind of Louis unwillingly reverted to the assembly of the Notables. It was already too evident, that they would not assist in extracting the king out of his difficulties, unless they were re-compensed for their interference and assistance, by a compliance with their demands; and it was equally evident, that their demands would go far to reduce the royal authority to that limited condition in which it had been before the reign of Louis XI. Louis, however, had gone too far to recede; and even if he could have receded, and dismissed the Notables, how was he to recruit the finances of the kingdom? It was therefore necessary to gain the good will, or at least to avoid, as much as possible, exciting the discontent and suspicion of the assembly; and, for this purpose, the Archbishop of Toulouse was appointed to superintend the finances, instead of Calonne. But he soon found that it was more easy to object to the schemes which his predecessor had presented, than to offer any thing more satisfactory; and he was under the necessity of again proposing the territorial impost. The objections and opposition to it were now more violent than before, as the assembly plainly perceived, that the kingdom was in such a state, as to have placed the sovereign completely in their power. Louis was thus placed in a state of great embarrassment; but, at length, he determined to dissolve an assembly from which he had received no support or advantage, but which, on the contrary, had only increased the difficulties in which he was previously involved. On the dismissal of the assembly, royal edicts were issued for raising money; to these the parliament of Paris objected, in such peremptory language, that Louis was under the necessity of holding what is termed a Bed of Justice, and compelling them to enrol the edicts. In former times, the Parliament would most probably have submitted after this step; but now they were emboldened by the sense of their own power, and the unequivocal symptoms of disfranchisement, which had spread over the whole kingdom, to protest against the enrolment as a compulsory measure; and to declare that the first person who should attempt to carry the edict into execution, should be pus-

This stretch of authority, which interest or prudence might induce him soon to relax. His first action, after leaving the Assembly, was one of vigour and boldness. The Duke of Orleans was banished to one of his seats; and 

letters de cachet were issued against two of the members of the parliament, who had been most violent in the debate. To the remonstrances of the parliament against these proceedings, Louis at first replied in authoritative language: but about the beginning of 1788, he yielded, and the Duke of Orleans was recalled, and the two members liberated.

Hitherto the parliament of Paris had confined its efforts to opposing the measures of the King; or, when they did advert to the establishment of civil and political liberty in France, it was only in general terms; but now they directed their invectives against 

lettres de cachet, which had, the previous year, been remonstrated against by the parliament of Grenoble. These invectives again excited the severity of Louis; the parliament was surrounded by troops, and the obnoxious members seized. Their language on this occasion was even more bold than it had ever been before; as they did not hesitate to tell the King, that his authority could only be esteemed and supported so long as it was founded on justice. Compared with this opposition to the royal will, the measures of the Notables had been mild and respectful; and Louis therefore resolved to assemble them again. As soon as they met, the keeper of the seals explained his Majesty’s pleasure, that a cour pleniere should be established; this proposition was favourably received by the Notables, but the parliament of Paris protested against it. This opposition, in connection with some serious disturbances that took place in the capital, at length induced Louis to recall Necker to the administration.

This minister soon perceived that the royal authority was very considerably weakened since he was in power before, and that he had only the choice of difficult, and even hazardous, expedients. But decision was absolutely necessary; and as it was of the utmost importance for the King to regain the confidence and loyalty of his subjects, the minister strongly recommended that the States-General should be assembled. From the opposition which the parliament of Paris made to this measure, he argued that it would at least serve to diminish their influence.

The principal difficulty respecting the States-General, arose from the opposition of the nobility and clergy to the representatives of the Commons being equal in number to the other two orders united. The Count D’Artois headed the party which contended that the representatives of the Commons ought to be confined to a third in number of the States-General. The opinion of the Duke of Orleans was supported by Necker, and sanctioned by the King. The number of deputies was fixed at upwards of 1000, and the representatives of the Commons were to be returned according to the population of the different districts of the kingdom.

On the 5th of May 1789, the assembly of the States-General was opened by the King at Versailles. His Majesty’s speech was conciliating and prudent; he did not affect to conceal the discontent of the people, while he expressed his firm conviction, that the causes of these discontent, so far as they were real and just, would be removed by the wisdom and patriotism of the Assembly. He no longer used the language of a sovereign, who expected implicit obedience to his will; on the contrary, he expressly represented his power as that of a just king.

Conduct of the Duke of Orleans.

Waiving conduct of Louis.

VOL. IX. PART II.
in the midst of a people faithful and ever devoted to the principles of the monarchy. The speech of Necker was by no means calculated to strengthen the good effects of the speech of the King; as he represented the assembling of the States General, not as a constitutional right, but as the effect of royal compliance. He thus excited the suspicion and ill will of the third estate, while he did not conciliate those who had all along regarded him as the enemy of the privileges of the other branches of the Assembly.

A difficulty not unforeseen, arose in the very first meeting; for the nobility and clergy seemed resolved to decide every question by a majority of the orders taken separately, and, as a preliminary step, retired to their respective chambers to verify their votes. To this the commons strongly objected; but as their objections were not attended to, they proceeded to business separately; the nobility did the same; the clergy, however, offered their mediation between the contending parties.

From these proceedings it was too evident that the Assembly was constituted in such a manner as not to promise unanimity, and consequently that the object of its meeting would not be fulfilled. The distresses of the state, which they were met to deliberate upon and remedy, could not be removed effectually and permanently, until a more equal and productive system of taxation were established. Nor could the discontent of the people be pacified, until the abuses, against which they had lifted up their voice, had been put down; and yet as the nobility and clergy were principally concerned in both these objects, it was desirable that they should manifest a conciliating spirit. Between the period of its first meeting and the beginning of June, several of the clergy, and a few of the nobility, had agreed to act along with the commons; but as the rest were refractory, the Abbé Sieyes, on the 15th of that month, made a motion, the object of which was to declare, that the commons, with such members of the nobility and clergy as had united with them, were the known and acknowledged representatives of the nation. On the following day this motion was carried; and the appellation of National Assembly was given to the meeting.

Their very first measures plainly indicated the spirit by which they were actuated. All taxes were declared illegal, because they had not received the consent of the nation; but so long as the National Assembly sat, they might be levied; the moment it was dissolved, the people were no longer bound to pay them. The public debt was placed under the protection of the honour and faith of the French nation; and a committee was immediately appointed, to enquire into the causes and remedy of the dearth which then afflicted the kingdom.

Thus did Louis find, that his authority was in a great measure wrested from him by the National Assembly; and the great body of the nobility and clergy, by their refusal to unite with the commons, likewise saw themselves shut out from power, and their privileges invaded. It was not to be expected that either would patiently submit. On the 21st of June, when the deputies of the National Assembly attempted to enter their place of meeting, the door was shut against them, under the pretext, that preparations were making for the royal presence on the 23d. They immediately retired to a neighbouring tennis court, where they unanimously took an oath to consider themselves as inseparable, and to continue to meet wherever they possibly could. On the following day, many more of the clergy joined them, and M. Bailly was declared president of the National Assembly. On the 23d, the King met the three orders in the grand saloon. He reproached the proceedings of the commons; and the keeper of the seals in his name declared, that the distinction of the three orders was essential; that the proceedings of the commons had been illegal; and that the saloon should be closed to the public in general. A second and third declaration followed, in which the subjects for deliberation, and the wishes of the King, were pointed out. When his Majesty retired, he commanded the three orders to separate. The nobility almost unanimously obeyed, and most of the clergy; but the commons were firm, and, before they adjourned, agreed to the motion of Mirabeau, "that the person of every deputy should be regarded as inviolable."

The crisis which now seemed fast approaching, was delayed for a short time, by the King's desire of tranquillity. This induced him to recommend the nobility and clergy to join the commons; and the junction accordingly took place on the 27th of June. Some of the members of these orders refused to obey the King; but as they were not numerous, they could no longer hope to oppose the commons.

It was not to be expected, that the citizens of Paris should be indifferent in the midst of these commotions; on the contrary, all the points in dispute between the King and the National Assembly were discussed by them with a wonderful degree of boldness; and symptoms began to manifest themselves of a feeling decidedly hostile to the established government. With a few, perhaps, this feeling originated from a calm and dispassionate conviction, that there were gross abuses in the state, which ought to be removed, and which could be removed without endangering the tranquillity of the nation, or altering the fundamental constitution of the kingdom; but with the great majority of the citizens of Paris, this feeling arose from an undefined and vague desire of change, violent in its nature, and uncertain in its means or object. Such being the state of mind in the metropolis, and such the conduct of the National Assembly, it was too evident, that unless the councils of the king were directed with a most uncommon share of moderation and firmness united, they could not extricate him from the impending danger. But no such qualities existed in his councils; be himself indeed was mild and conciliating; but as such, his conduct was only the more calculated to do harm, since those measures which he himself approved and adopted were done away, probably the next day, by the unbending harshness of his advisers. These influenced him so far, as to gain his sanction to the assembling large bodies of troops in the capital and its vicinity. The consequences were such as might have been anticipated. These troops were not sufficiently strong to keep down the citizens, while they were exposed to be insulted by them; commotions took place; and during the irritated state of the public mind, Monsieur Necker was dismissed from his situation.

This was the signal for insurrection in Paris; and the King again yielded, declaring that the troops should be withdrawn, and that the citizens should be permitted to form themselves into military bodies. But this concession was too late; the regular troops and the citizens had already fought; blood had been shed; and the French guards had, in this rencontre, joined the people. The bastile was the first object of the popular hatred and fury; in a short time, not a single stone remained; the governor, who had opposed the people, was dragged to a place of execution, and his head, severed from his body, was carried in triumph through the streets.
The King now perceived that his sole reliance must be on the army, since it was absolutely necessary to restore order and obedience before he could go on with his plans of reformation; but the army, which had always been characterised by their extreme devotion to the Monarch, openly declared that they would not fight against their fellow-citizens. No alternative therefore remained for the King, but concession. Necker was recalled; the King himself returned from Versailles to Paris; and was obliged to submit to the speech of M. Bailly, (who had been chosen mayor,) on delivering the keys of the capital, in which he plainly told him, that the people had that day reconquered their king.

Louis had already signified his approbation of the plan of forming a national militia; or in other words, an armed body, who would obey not him, but the National Assembly; it had been accordingly formed, and the Marquis de la Fayette, whom we have already mentioned as having gone to fight in the cause of American independence, was appointed colonel: this appointment, Louis deemed it prudent to sanction. At this period the more obnoxious members of the royal family, as well as several of the nobility, determined to leave France; they were induced to do, not merely from regard to their own safety, but because they hoped to influence foreign powers to support the royal cause. Among these emigrants, the most celebrated were the Count D'Artois, the Prince of Condé, and the Marshal Broglio.

The King still pursued his plan of concession and conciliation; corn was brought into the capital, in order to reduce its price there; and corporal punishment was abolished in the army. By these measures the tranquillity of Paris was preserved for a short time; but the provinces were in a state of complete anarchy; the peasantry rose, and destroyed the churches and seats of the nobility with savage fury; the more obnoxious of the nobles were seized and exposed to the most barbarous and lingering deaths.

The return of Necker was celebrated at Paris with so much joy, that it was hoped his influence might restore tranquillity and obedience; but he soon found that circumstances were radically and fatally changed during his absence; and his very first attempt to procure a general amnesty was defeated. Fresh commotions arose, and were marked by additional excesses and cruelties. At St Denis, Caen, and Strasbourg, the conduct of the populace would have disgraced the most barbarous periods of the most barbarous nations that ever existed; it was no longer the reformation of abuses, even by violent means, that they aimed at; but the gratification of the most diabolical passions. The revenge too, which they took, was, in most instances, cowardly in the extreme; and extended even to those who had been their best friends and greatest benefactors, merely because they belonged to the class of the nobility, or because they endeavoured to bring them back to a sense of their duty and real vocation.

The members of the National Assembly were the enlightened advocates of liberty, and the true friends of their country, they would have exerted their influence, in the first place, and above all other considerations, to the repression of anarchy and the restoration of obedience, from the conviction, that whatever they might decree in their meetings respecting the political or civil privileges of the people, could not be enjoyed by them, till they were restored to a sense of their duties, and of the necessity as well as advantage of obedience and order. But the Assembly, instead of endeavouring to repress the tumults which disgraced the capital and the provinces of France,—instead even of enacting laws which were applicable to the state of the country, and which might gradually have conducted, at once, to restore the privileges and liberties of the people, and to repress their licentiousness,—instead of acting in this sensible manner, they spent their time in discussing abstract propositions, which either were unintelligible, or could not possibly have any practical application to the existing state of the country. Had France been in perfect tranquillity, and every law been passed which was essential to preserve that tranquillity, and to secure the liberty of the subject, such discussions might have been excused, because they would have done little harm, and most have occupied time and abilities which had much more urgent demands upon them; but when the machinery of the state was in complete disorder, and at the same time working with the most mischievous and fatal rapidity, it was absurd and criminal in the highest degree, to be discussing the principles on which it had been, or might be, constructed, instead of repairing its defects. Yet such was the conduct of the National Assembly.

The abstract proposition of the rights of man, which, besides being abstract, and therefore improper for the discussion of the Assembly, was not very intelligible, occupied their time and attention at the very period when the smallest reflection, the most limited practical knowledge of mankind, might have convinced them, that the people of France could not be put in possession of their rights with advantage to themselves, or with safety to the community, while they continued so forgetful of their duties, as to give themselves up to anarchy, plunder, and murder.

The other discussions of the National Assembly were on subjects more practical, and therefore more fitted to their character and situation; but even these should have been postponed till they had proved their authority over the people, by restoring order and tranquillity. The feudal system, in all its branches, was abolished; the public burdens were equalized; the most oppressive taxes were repealed; the clergy gave up their territorial rights; and a resolution was passed to inquire into the pensions granted by the court. As the King did not oppose these proceedings, he became popular for a short time, and was honoured with the appellation of the Restorer of the Liberties of France. Indeed, it was now evident, that if he did not yield to the storm, he would be overwhelmed by it, for he had no supporters; even the Swiss and French guards had deserted him.

Could observation and experience have taught the National Assembly the folly of their conduct, in not beginning by repressing the insurrectionary spirit of the people, they would have learnt wisdom by the events of each passing day. In Paris corn was still dear; and the people, let loose from all restraint, were still more goaded on to licentiousness, by this circumstance. In the provinces, the peasantry, taking advantage of the abolition of the feudal rights, plunged into the most dreadful excesses; the nobility were murdered; justice was set at nought; and even the harvest, the means of their own future support, suffered from their blind and ungovernable fury.

If the revenue of the country was inadequate to its financial expenditure, when every thing was tranquil, and when distress no corn was imported, the deficiency must necessarily have been augmented considerably, during the suspension of labour, the importation of corn, and the de-
Adopt that side of every question which they knew would meet the approbation of the multitudes who filled the galleries. The month of August was consumed in debates about the veto, which at length was indirectly negatived by the decrees that were passed for the formation of the constitution. These decrees were in some respects rational and practical; but they were preceded by a declaration of the rights of men and citizens, so speculative and metaphysical, where it was well founded, as to be of no utility; and in other points calculated to mislead and inflame the ignorant and already maddened populaces. The decree respecting the constitution, went to establish a limited monarchy and to create completely the legislative from the executive powers: but it is unnecessary to give the details of this or of any other of the numerous constitutions which were made in France; it is sufficient to notice the leading principles on which they were grounded.

To the most negligent observer, the state of the capital at this period must have appeared very threatening. Parties ran excessively high; and on neither side was there moderation. But the most alarming symptoms were, that a most active and numerous association was evidently forming, who regarded even those who had hitherto taken the lead against the royal party, as lukewarm, and stopping far short of what they ought to have achieved. On the feelings of the lowest of the mob, this third party organized; with wonderful but most mischievous effect. The scarcity which still existed, was ascribed to government. A report that the King intended to leave Versailles, and probably the kingdom, was industriously spread, and the most innocent actions of the royal family were grossly misrepresented. Unfortunately the Queen did not conduct herself with that reserved and prudent caution which her unpopularity, and the circumstances of the times, absolutely required. At an entertainment, given by the garde du corps, to the regiment of Flanders, which had been ordered to Versailles to protect the King, the national cockade, which had been lately adopted, was thrown aside, and white cockades supplied by the ladies of the court. This imprudent behaviour was soon known at Paris, where, while the people were suffering under the pressure of famine, they learned that a splendid entertainment had been given at Versailles, as if to insult their misery, and that the symbol of that constitution, from which they expected the removal of their grievances, had been supplanted by the symbol of that government, to which they ascribed them. The populace were joined by the militia of Paris and the ancient French guards; and the Marquis de la Fayette was informed that they were determined to go to Versailles, to exterminate those who had insulted the national cockade, and even to depose the King, if he did not protect and relieve them. The Marquis employed his influence and authority in vain. An immense number of women of the lowest rank, clamorous for bread, and rather encouraged than prevented by the military, set off for Versailles. As soon as they arrived, they besieged the National Assembly, and, in a manner, compelled them to send along with them, to the King, a delegation of their members. In the mean time, La Fayette, having collected the national guard, also arrived. He first presented himself to the National Assembly, and afterwards went to protect the King and royal family. The Queen was the principal object of the fury of the populace, and a desperate attempt was made on her life; but she, as well as the rest of the royal family, were saved by the interposition of La Fayette.
but they were obliged to promise to leave Versailles, and go to Paris immediately. The journey was dreadful, not only in its actual circumstances, but as a dreadful foreboding of what was to come. Before, around, and behind the royal family, were a mob of frantic women, debauched and drunken, attended and cheered by men, if possible, more diabolical than themselves. The procession was headed by two men, who, with their arms naked and bloody, displayed aloft, on their pikes, the heads of two of the garde du corps, whom they had massacred.

The oncoming triumph of the unprincipled and ferocious party, who were anxious to lay hold of all the power, in order that they might gratify their diabolical passions, was now nearly complete. By having forced the King and the National Assembly to Paris, they had succeeded in overthrowing them both, and in virtually placing all authority in the mob. In vain did the King declare his willingness to adopt any measure that would benefit the nation; in vain did the National Assembly, while they declared themselves the advocates and supporters of liberty, decry their licentiousness. Every day beheld their authority tottering, and the influence of the most desperate and abandoned of the inhabitants of Paris increasing. The Duke of Orleans secretly encouraged the licentiousness of the mob; and though, for a short time, he was persuaded by La Fayette to retire to England, yet he soon returned; and, even during his absence, his emissaries were at work, carrying on their measures of anarchy and licentiousness.

The principal proceedings of the National Assembly during the remaining part of the year 1789, related to the division of the kingdom into departments, and the confiscation of the church lands. Early in the following year, they suppressed the monastic establishments and confiscated their lands. These decrees evidently tended to conciliate the people at large: in June the army and navy were in a great measure gained over, or kept firmly attached to the National Assembly, by the passing of decrees for the augmentation of their pay.

In the mean time, the emigrants from France were active and indefatigable in their endeavours to stir up foreign powers in their behalf; and the proceedings which had lately taken place in Paris, and in different provinces, gave them too strong pretexts for urging their interference. It was therefore necessary for the Assembly to provide for the not improbable case of a speedy war; and when M. Montmorency communicated to them the hostile preparations in which England and Spain were engaged, respecting a right of fishery on the coast of America, the question was discussed, "Who ought to possess the power of declaring peace or war?" The debate was long, and conducted with considerableanimationand talent, but the time was gone by, when the royal party, however wise their measures, or strong their arguments might be, could reasonably expect to carry their point. On this occasion the triumph of the popular party was complete; and it was decreed that the right of peace or war belonged to the nation.

As the Assembly were sensible that their proceedings were viewed with suspicion and jealousy by foreign powers, they decreed that the French nation would never embark in any war with a view to conquest, nor ever employ their forces against the liberties of any people. Thus was the crown, in a very short time, stripped not only of its unjust and hurtful prerogatives, but also of those which were necessary to give it due and proper weight, and to preserve to the constitution the reality as well as the name of a monarchy.

On the 19th of June, a motion was made to suppress all hereditary titles, livresses, and coats of arms. This was also carried; and, of all the King's ministers, Necker alone, a plebeian, bred and born in a democracy, and who had always professed republican principles, advised his Majesty to refuse his assent to the decree.

The French are fond of spectacle; and of this fondness it was now resolved to take advantage. The Bastille had been destroyed on the 14th of July the preceding year. As the anniversary of this event was now approaching, it was proposed that on that day a civic oath should be taken. The Champ de Mars, a spacious plain which adjoins the capital, was fixed on for the ceremony. In the midst of it an altar was placed, and around the altar an amphitheatre was constructed, capable of containing 400,000 people. At 4 o'clock in the evening, the Marquis de la Fayette ascended the altar, and took an oath to be faithful to the nation, the law, and the King: the deputies of the regular troops and militia repeated, "I swear." The Marquis was followed by the president of the National Assembly, who took an oath varying in substance a little from that taken by the military; and each deputy repeated aloud, after the president, "I swear." The King also, stretching his arm towards the altar, took an oath to employ all the power delegated to him by the constitution, for the maintenance of the constitution, and the execution of the law.

Necker had long been convinced that his influence was on the wane, and that, even if he still enjoyed it undiminished, he could do no good, either in restraining the blind fury of political innovation, or in restoring order to the finances; he was besides a vain man; and, as has been already remarked, more conversant in detail than in general principles and comprehensive views. On the 4th of September he gave in his resignation.

The hostile preparations of Germany, Spain, Italy, and Savoy, had, in the beginning of 1791, assumed a character that could leave little doubt they were intended against France. With respect to Germany, the German princes, who possessed territory on the north side of the Rhine, could not be indifferent spectators of a revolution in their immediate neighbourhood, which had stripped the French nobility of all their privileges, and, in many instances, had deprived them of their lives. Besides, the German peasants were not slow in following the example set them by their brethren in France; so that what they had actually suffered, as well as the dangers they apprehended, stimulated the German princes against the Revolution. In their apprehensions of future danger, the other princes, at present remote from the example and influence of the Revolution, were not slow in participating; and these apprehensions likewise took hold of several of the sovereigns of Europe. There were also other considerations which influenced some of them: the Emperor of Germany was naturally anxious respecting the fate of his sister, the Queen of France, who was peculiarly obnoxious to the Revolutionists; and the King of Spain could not behold with indifference one branch of the Bourbons stript almost entirely of regal power, and the King, as it were, the slave of his own people.

The Parisians, alarmed at these hostile preparations, were suspicious that the King was consenting to them; and their suspicions were increased and strengthened by the departure, in the month of February, of his
Juntas from Paris. Nor were they satisfied by the declaration of Louis, that as the laws did not lay them under any restraint, he did not oppose their departure. They naturally concluded that the King had a design of following them, and of joining an emigrant force, which was now collecting on the borders of Alsace.

All his motions were watched with such jealousy, that, on the 18th of April, as the royal family were preparing to go to St Cloud, a report was spread that they were about to emigrate, and their carriages were immediately surrounded and stopp'd by the people. La Fayette upon this, called out the national guard, but they refused to act; and he was so much hurt at their refusal, that he resigned his command; nor was he, without a very general and pressing solicitation, prevailed upon to accept it again.

The suspicions of the people respecting the intended flight of the royal party were well founded; but it was delayed, till it was hoped it might be effected safely and certainly. The Marquis de Bouillé, who commanded on the frontiers, removed the national guards, and replaced them by such troops as he could depend upon; and in the whole of the route which the royal party were to pursue, every thing, which could facilitate their escape had been prepared with as much order and secrecy as possible. On the 21st of June, it was ascertained that the royal family had left the capital in such a secret manner, that no doubt could be entertained of their intention of quitting France. Immediately all was consternation and commotion, mixed with unbridled fury, among the populace. The National Assembly were more cool and composed: they declared their sitting permanent, and assumed the government. As the route of the royal fugitives was unknown, messengers were dispatched in all directions. Their fate was not long in suspense. Monsieur and Madame arrived safely at Brussels; but the King, Queen, and Dauphin were arrested at Varennes, within a very short distance of the frontiers. This unfortunate attempt excited in the multitude such an abhorrence of the King, whom they suspected of an intention to join the emigrant army, and to invade France, that his most sanguine friends could now no longer hope he would regain their confidence or loyalty; and this feeling of the multitude was cherished and exasperated by all those, who were determined to destroy even the name and vestiges of a monarchy, and to substitute in its room, either an undefined and speculative democracy, or the unrestrained power of the mob; for about this period, those men began silently and secretly to use their influence, who afterwards plunged France into an unparalleled state of crime and wretchedness.

As the plan for the King’s flight had been well arranged, and consequently its success had been anticipated, many of his friends, who had hitherto remained in France, now emigrated. The Marquis de Bouillé, who was one of these, afterwards sent a very foolish and mischievous letter to the National Assembly, in which he denounced vengeance to them, and the utter destruction of Paris, if the lives of the royal family were in danger. He added, that he would conduct the foreign armies into France, and that his letter was but the fore-runner of the manifesto of the sovereigns of Europe. As danger from abroad was undoubtedly approaching, the National Assembly considered it their duty to guard against it by every possible preparation; but it was also desirable to rouse the passions of the multitude to such a pitch, as would induce them to come forward, as with one heart, in defence of their country. The letter of the Marquis de Bouillé had in some degree this effect; but their purpose was still more completely answered, by the circulation in France of what was called the treaty of Pihotz. The authenticity of this treaty has been denied; but whether authentic or not, as it produced a wonderful effect on the French nation, it requires to be noticed. It purported to be a partition treaty between certain of the powers of Europe, by which they agreed to make war on France, and to recompense themselves for the expences of the war, and the restoration of Louis to his full authority, by annexing certain parts of the territories of France to their own dominions. In the mean time, the National Assembly, on the 3d of September, presented the new constitution to the King. For reasons already stated, it is unnecessary to give the details of it, especially as the leading principles on which it is grounded have been noticed before. The King having accepted the constitution, the National Assembly dissolved itself on the 30th of September. From its principal and professed object having been the formation of a constitution, it is generally denominated the Constituent Assembly.

The next Assembly, which was elected according to the forms prescribed in the new constitution, met on the 7th of October. The members of it were entirely new, as the members of the Constituent Assembly, by their own decrees, were excluded from holding seats in it. One of their first decrees respected the emigrants, who were assembling in considerable numbers on the frontiers of France: the punishment of death was denounced against them, if they should continue thus after the 1st of January 1792. Severe decrees also were passed against the refractory clergy, or those who refused to take the civic oath; but the King refused to sanction these decrees. In order to qualify this refusal, he intimated to the Assembly, that the Elector of Triage, on whose territories the emigrants were assembling, ought to be considered as the enemy of France, unless he put a stop to their hostile preparations by the commencement of the following year. This intimation gave considerable satisfaction, and in some measure, for a short time, restored the popularity of the King. This satisfaction was also increased by the declarations received from foreign powers, which expressed, in cautious, and perhaps ambiguous language however, their wish to preserve peace with France. But it was impossible that Louis could long retain it permanently; he was too much under the influence of those who were regarded with suspicion by the republican party, and the republican party themselves were too eager for an opportunity to censure the King. That this party was gaining strength, at least in the capital, was evinced by a circumstance which happened there in the month of November. At this time the majority of Bailly expired; the candidates were La Fayette and Pétion; a very few months before, the popularity of the former was so great, that no person would have wished or dared to have opposed him; but now Pétion, a violent republican, was elected mayor by a great majority.

It is evident from this, that the republicans were State of not only strong, but well organised; in fact, they had parties held, for some time, their regular meetings; and from the place of their assembling, they had received or assumed the name of Jacobins. To oppose them, some of the most celebrated members of the Constituent Assembly formed themselves into a society, which derived its name from the convent of the Feuillants, where they assembled. Among them were Rabaud, Sieyes, Talleyrand, Montesquieu, &c.
The hostile preparations of the emigrants, and of the foreign powers, still went on; nor were they delayed in the least by the death of the Emperor of Germany, or the murder of the King of Sweden. As the French minister for foreign affairs did not use corresponding diligence and exertions, he was accused, even during his absence, by Brissot, apprehended, tried at Orleans, and executed. The management of affairs was next placed in the hands of those, who would not fail to make all due preparation for the hostilities which threatened France. Dumourier was appointed minister of war, Roland minister of the interior, and Claviere minister of finance. This completed the triumph, and established the power of the republicans. One of the first acts of this party was to confiscate the property of the emigrants; their next was to declare war, on the 20th of April, against the king of Hungary and Bohemia, in consequence of the Imperial minister demanding the restoration to the German princes of their feudal rights; the restoration of Avignon to the Pope; and that the neighbouring powers should have no reason for apprehension, from the weakness of the internal government of France.

The French armies immediately invaded the Austrian Netherlands; but the plan of the campaign was contrived with so little foresight or wisdom, and, from the want of discipline and experience in the troops, so miserably executed, that it was productive of no advantage to the French. Indeed it was evident, that unless their troops were more obedient to their officers, they would do more mischief to the cause of France than to that of the enemy; and yet such was the state of the public feeling, both in the army and at Paris, that the evil seemed more likely to increase than diminish. In the capital, party spirit was very violent; but the Jacobins were evidently gaining ground; and the measures they adopted for increasing their own influence with the people, and diminishing that of their opponents, could not fail of effect. They circulated reports of intrigue and conspiracy in favour of the enemies of the country; the mob, credulous, easily alarmed, and now accustomed to regard the aristocratical party as decidedly hostile to their interests, as well as the lawful objects of their vengeance, rioted round the Jacobins, and supported, in a violent and tumultuous manner, their most extravagant propositions. For some time the King yielded to them; but, like all his former conduct during the Revolution, after having given them his countenance, and thus increased their power, he altered his conduct, and, when it was too late, resolved to oppose them. The ministry were dismissed, except Dumourier, who, by being thus excepted by the King, became an object of suspicion with the Jacobin club; he thereupon resigned his office, and joined the army. About this time, Marat, afterwards so infamously notorious, appeared on the stage, and, by his inflammatory writings and harangues, contributed much to increase the unpopularity of the king. On the 20th of June, an armed mob marched through the Assembly, under the pretence of presenting petitions; they afterwards, to the number of 40,000, surrounded the Thilleries, and insulted the king. As soon as these disgraceful events were known in the army, La Fayette left it, and presented himself at the bar of the National Assembly, where he expressed the indignation of the troops, and called upon the Assembly to prevent the repetition of such scenes, by punishing the promoters of them, and especially by dissolving the factious clubs. But the power of the Assembly was vain against clubs supported by the most numerous, the most desperate, and the most worthless part of the population of Paris; in them, in fact, was centered the government of the capital, or rather in the Jacobin club, which ruled and moulded them at its pleasure.

To these dreadful internal evils was now added an approaching invasion. The King of Prussia, in conjunction with Austria, was marching against France with an immense force; while the French armies were comparatively few in number, and by no means equal to their opponents in respect to the discipline and obedience of the soldiers, or the talents and experience of the officers. But their deficiencies, in these respects, it was hoped, would be more than compensated by their enthusiasm, and by the co-operation of the people. These, however, it was necessary to rouse, and for this purpose the Assembly ordered a proclamation to be made that the country was in danger. This object, however, was more effectually accomplished, by a manifesto, issued by the Duke of Brunswick, as commander of the invading army, at Coblenz, on the 25th of July. In this manifesto, destruction to Paris, and the execution of all who resisted, were denounced; and the safety of the royal family was declared to be the only condition on which the capital, or the National Assembly, could possibly escape the severest vengeance of the allied powers. The immediate consequence of this impudent and impolitic manifesto, was the union of all parties, for their mutual defence, and the support of what they conceived to be the will of the nation, and the independence of France.

However they might differ, and quarrel among themselves, all felt and acted on the necessity, at the present moment, of opposing the allied powers, who entered France with such declarations of vengeance. The friends of the King soon fatally experienced the extent of mischief to him and his cause, which this manifesto produced. The republicans, long anxious for his deposition, now saw too good an opportunity to be neglected;—for who, thought they, would dare to defend a King, who was such an enemy to France, as to have his safety put to a competition with its liberty and independence! But it was necessary, even yet, to proceed with caution in the deposition of Louis: the republicans could not expect that the National Assembly would willingly agree to it. They had accused La Fayette before it, and he had been acquitted; and hence they inferred, that their measures respecting the King would not be well received by that Assembly; it was therefore their object to excite the worst passions of the populace against him.

In Paris, at this time, there were too many, who might easily be made the zealous instruments of the worst crimes; for, besides the mob of the city, 15,000 Marseillais had arrived at the period of the confederation, on the 14th of July, not the least behind the most unprincipled and ferocious of the Parisians in their hatred of royalty and order, and in their disposition to excite disturbance, and to commit murder. With these, and the mob of Paris, the republicans intrigued, and the friends of Louis were not long in perceiving that his life was in danger. The palace, therefore, was guarded by a number of gentlemen, by the Swiss troops, and by 12 pieces of cannon. Mandat, the commander of the national guards, was at their head. At midnight, on the 9th of August, the tocsin sounded, and the drums beat to arms; but the republicans knew that while Mandat
lived, their efforts against the life of the King would be
unavailing; they therefore contrived to persuade him to
leave his post, and come to the commune, which was
entirely composed of their own friends; and as he was
leaving the hall, he was shot, and Santerre appointed to
command the national guard in his place.

On the 10th of August, Louis found himself placed in
such a perilous situation, in the palace, that he sought
protection in the National Assembly. Immediately after
he left the Tuileries, the insurgents, to the number of
20,000 men, attacked the Swiss who guarded it: a bloody
combat ensued; but the Swiss were overpowered, and
most of them massacred. The republican party, now
strong in the success which had attended their first ef-
forts, and in the terror which they had excited, resolved
to push the execution of their favourite object imme-
diately; the royal authority was suspended; the nation
invited to choose a convention; commissioners sent to
the army; and the royal family imprisoned in the Tem-
ple.

The influence which Lafayette possessed with the
army, it was hoped, by the friends of the king and of
justice and order, would preserve them loyal and ob-
dient; but they were not to be depended upon, and La
Fayette judged it prudent to leave the camp, soon after
intelligence of the transactions at Paris had arrived, and
to seek his safety in flight. He escaped from his own
troops, but he was made prisoner by the enemy, and de-
tained in Austrian and Prussian dungeons for several
years. The commissioners now found no opposition to
the authority of which they were empowered to exercise
over the army; but were received with respect by Ge-
nerals Dumourier, Biron, Montesquieu, Kellerman,
and Custine. Dumourier, having removed the suspicions
formerly entertained of him by the republicans, was
appointed commander-in-chief, on the flight of La Fayette.
This general was at the head of about 17,000 men, and,
with this inadequate force, his object was to watch, for
he could not hope to oppose, the progress of the allied
forces. These had entered France so numerous and well
equipped, that the conquest of that country seemed cer-
tain and near at hand. The Duke of Brunswick had
50,000 Prussians; there were 15,000 Austrians under
Clairfait; and the Hessians and French emigrants raised
the total force to 90,000 men. Their success at first was
proportioned to their strength and their hopes. Longwy
and Verdun surrendered, and Paris was already in alarm.

This moment of alarm was not to be overlooked by
the Jacobin party,—it was too favourable to their views.
They declared that the safety of the country, and the
destruction of foreign foes, could not be accomplished,
while there existed in Paris so many domestic enemies
of the people. The most horrid massacres accordingly
took place, at which the forms of justice were either enti-
tirely neglected, or attended to in such a manner, as to
render the proceedings still more repulsive to humanity.
For two days, the mob, under the direction of Marat,
Robespierre, and Danton, who now led the common
Council, had the entire possession of Paris; no person
besides durst stir out of their house; the national guards
at this crisis seemed disposed to interfere, but Santerre
was too strongly attached to the violent Jacobins to re-
press cruelties which they had organized and directed.
The massacres did not cease, nor was even the ap-
pearance of order and tranquillity completely re-es-
tablished in the capital, till intelligence arrived that the all-
ies had commenced their retreat out of France. For
some time after the reduction of Verdun, they had ad-
vanced with little or no opposition; but as soon as Du-
mourier had organised his army, he opposed consider-
able obstacles to their farther progress, and some battles
were fought, in which the French behaved with great
coolness, and evidently showed that they were improved
in discipline. Notwithstanding this, however, and the
additional circumstance, that the troops under his com-
mand were much increased; Dumourier would not have
been able to save his country, had not sickness and fa-
mine attacked the Prussians. The former originated
from the soldiers eating large quantities of fruit, and
from the unusual wetness of the season; the latter took
its rise from the inhabitants absolutely refusing to carry
provisions to the camp of the enemy. It has been sus-
ppected that, even in spite of the reduction in the strength
and spirits of his soldiers, which sickness and famine
produced, the Duke of Brunswick might have driven
the French army before him, if the King of Prussia had
continued firm to the cause of the allies. However this
may be, after a truce of eight days, he commenced his re-
treat. He was not pursued, but Verdun and Longwy were
retaken, and Thionville, which had been gallantly defended
by General Wimpfen was relieved. The Austrians were
not more successful than the Prussians; for after besieging
Lisle for a fortnight without the least prospect of re-
ducing it, they raised the siege. On the side of Savoy,
the French were the invaders, and they were received
by the people with great joy and enthusiasm. The suc-
cess which had attended the defence of their own terri-
tries, made them forget that they had declared they
would not invade the territories of other nations: not
only was Savoy invaded, but Spires, Worms, Mentz,
and Frankfort were attacked and taken before the close
of 1792. The last place, however, did not remain long
in their possession, as it was re captures on the 2d of
December in that year. In the Netherlands, the French
were still more successful. On the 6th of November,
Dumourier attacked the Austrians, who were strongly
fortified on the heights of Jemappe. The battle was most
obstinate and bloody, but French enthusiasm, joined to
superior numbers, succeeded; and this victory decided
the fate of the Austrian Netherlands.

In the mean time, the National Convention assembled;
the Jacobins, and as the republican party were by far the
most numerous, Convention.

It was carried by acclamation. The next day it was de-
creed that all acts should be dated by the year of
the Republie; and the appellation of citizen was universally
adopted. Still, notwithstanding these foolish and mad
acts, there were some men in the convention who did
not unite the utmost profifancy of principle and depra-
vity of conduct with their folly and madness. These
were the Girondists, or Brissotines; the most celebrated
and respectable of whom were Condorcet and Brissot.
The other party were denominated the Mountain, beca-
use the members of it usually sat on the upper seats
in the convention; of these, the most powerful and in-
famous were Danton, Robespierre, Marat, and Collot
D'Herbois. The Girondists were anxious to punish the
perpetrators of the massacres of the 2d and 3d of
September; but their motions to this effect were
always eluded by the Mountain party, who had been
chiefly instrumental in these massacres, and looked forward to their repetition as the means of intimidating their opponents, and establishing their own power. In October a decree was passed, that all emigrants when taken should suffer death; and in the following month, the Convention declared, in the name of the French nation, that they would grant fraternity and assistance to all people who were anxious to be free; and the generals were ordered to give assistance to all such. On the 11th of December, Louis was ordered to the bar of the Convention; and the act of accusation being read, he was required by the President to answer to each separate charge. These charges were very numerous; some of them were of a frivolous nature; others related to acts done either before the Revolution had defined and limited the royal authority, or in conformity to the constitution which had been established. Besides, that constitution had declared the King's person inviolable. There were, however, it must be confessed, some charges, which were more relevant, and better founded. These related to the connection that the King kept up with the emigrants and with foreign powers; but in defence of him, in this respect, it may be fairly urged, that his situation was such, that no wisdom, no purity of conduct, could have carried him through, free from suspicion and personal danger. What the legislative bodies, or the French people through them, declared to be the constitution one day, was set aside the next; so that the King, seeing a total want of system, and even of principle in the conduct of those who had wrested the royal power from him, and the adoption of measures which threatened not only his own safety, but the tranquillity and happiness of France, ought not to be severely condemned if he looked to foreign support.

After he had replied to the various charges, he was allowed to nominate his counsel. On the 26th of December, his defence was read at the bar of the Convention; and on the 16th of January 1793, after a discussion of 54 hours, the punishment of death was awarded by a small majority. On the 21st, the execution took place.

The weakness of Louis's mind, which had displayed itself so frequently and so fatally during the Revolution, disappeared when his misfortunes reached their height; then his whole conduct was firm, composed, and dignified; and he met his fate in a manner which surprised and awed even his enemies.

In the course of this year, France was at war with all Europe, except Sweden, Denmark, Switzerland, and Turkey. The grounds and operations of the war between her and Great Britain are given in the article BRITAIN, and therefore need not be repeated here.

After the conquest of the Austrian Netherlands, Dumourier advanced towards Holland: but he did not conduct his operations with judgment; for, dividing his forces too much, he was obliged, after advancing as far as Gertruydenburg, to retreat before General Clairfait with a considerable loss. After experiencing another defeat, towards which it is suspected his own treachery contributed, 6000 of his troops left the army, and went home to France. Their representations, and other circumstances, induced the Convention to send commissioners to the army; and Dumourier, finding that his troops refused to act with him, joined the Austrians. On the 8th of April, at a congress of the combined powers held at Antwerp, it was resolved to invade France for the express purpose of conquest. This resolution was immediately begun to be carried into execution. The Austrians advanced; and, after five different engagements with the French under General Dampier, in the last but one of which he was killed, they succeeded in reaching Valenciennes, and commenced the siege of it. About the same time, the Prussians having repulsed the French army under Custine, laid siege to Mentz. The advantages and progress of the allies created great alarm in Paris, but were not unacceptable to the party of the Mountain. Their object was the destruction of the Girondists; and to effect this, nothing else was necessary but to render them obnoxious to the people, as the enemies of liberty, and the friends of the allied powers. The Mountain party, on all occasions of violence and injustice, used as their instruments the mob of Paris, which was now regularly organised for that purpose. The capital was divided into forty-eight sections, and each section had its commune, or common hall, in which the most impudent and unprincipled directed the proceedings. On the 15th of April, the communes of all the sections petitioned the Convention, that the leaders of the Girondist party should be impeached and expelled. The Girondists retaliated by impeaching Marat; but he was acquitted. This was the prelude of their fall. The Convention was now no longer an independent body, but was overawed by the populace and the Mountain party. The latter, however, were not so powerful in the provinces as in Paris. Most of the southern departments declared the Mountain party outlawed, and broke out into open revolt. The northern departments, in general, adhered to them. Soon after their triumph, they lost one of their leading members,—Marat, who was stabbed by Charlotte Cordé, a woman who came to Paris for that purpose, and who gloried in the execution of a deed, which she thought the cause of freedom and of her country called upon her to perform.

In a fortnight after, the Mountain party gained the ascendency over the Girondists. They framed a new constitution, but it was never put in practice. They also established, or at least gave more vigour to the revolutionary tribunal, the object of which was to try crimes against the state in the most summary and arbitrary manner.

The allies, in the mean time, did not derive so much advantage from the distracted state of France as might have been expected; for, however the French might be divided among themselves, they seemed resolved that no foreign power should interfere in their quarrels, or trespass with impunity on their national independence. Vauban held out till the 27th of July, and Mentz nearly as long. The possession of these places seemed to open a direct and easy road into the heart of France. But success produced its usual consequences; the allies could not agree in their future plans, and on this account divided their forces. Unsuccessful attempts were made on Dunkirk, Cambray, and Boulogne. Prince Cobourg was repeatedly attacked by the French under Jourdan: The French soldiers, animated by the presence of commissioners from the Convention, stimulated by spirituous liquors, which were supplied them by crowds of women who attended the army for this purpose, and to carry off the wounded, and supported by a formidable and well-served train of artillery, were irresistible. The
Austria, and maritime Flanders was again invaded, and partly conquered by the French.

At this very period, when they were victorious on their frontiers against their enemies, a civil war raged in different parts of France. Lyons, Marseilles, and Toulon, still opposed the authority of the Mountain party, and of course of the Convention, who were completely subservient to the views and interests of this party. On the 8th of August, Lyons was attacked by the conventional troops, and though soon reduced almost to ruins, it did not surrender till the 8th of October, when its walls and public buildings were razed to the ground, and an immense number of its citizens destroyed, by firing grape shot among them; the usual mode of execution by the guillotine being too slow and easy a death for the voracious cruelty of the conquerors. Marseilles, terrified at the fate of Lyons, submitted; and Toulon put itself into the power of Lord Hood, who, however, was soon obliged to evacuate it.

This civil war was between two parties, each of whom was friendly to the revolution; but the civil war in La Vendée was of a different character. In this district of France, the Bourbons had numerous and powerful friends. Divided from the rest of France in some degree by its situation, and much more by the difference of the manners, language, and habits of the people, La Vendée had not participated in the change of opinions which had produced the revolution. Into it, as a secure retreat, many of the priests who had refused to take the civic oath had fled, and as the inhabitants were superstitious, the priests did not fail to call in the aid of religion to the cause of the Bourbons. At first, the insurgents of La Vendée were rapidly successful; they besieged Nantes, and even threatened Paris; but after a tedious war, in which the most dreadful cruelties were committed on both sides, they were reduced to apparent and temporary submission.

The grand conflict between the allies and the French, in the months of October, November, and December of this year, was on the Rhine. As the latter did not deem themselves sufficiently numerous to oppose their enemies, they had erected very strong fortifications at Weissemburg, on the Lauter. On the 13th of October, general Wurmser made an attack upon them with all his force, and, notwithstanding their strength, he succeeded with little difficulty in driving the French from their lines; from thence they retreated to Hagenaew; hence also they were driven; and they were subsequently defeated on the 25th and 27th. The design of the allies to conquer at least parts of France for themselves, was now manifested; for Wurmser refused to accept the surrender of Strasbourg, unless to his Imperial Majesty. As the defeats which the French had suffered were ascribed to treachery, or to a want of enthusiasm, commissioners were sent by the Convention to the army, who, by the severity of their measures, as well as by the doctrines they preached to the common soldiers, succeeded in rendering them victorious. This effect, however, must also be ascribed, in part, to the numerous reinforcements, which the measures adopted by the convention supplied to all the French armies, the nature of which will be afterwards explained. General Wurmser soon experienced the difference in the ardour and efforts of the army opposed to him, after the arrival of the commissioners; for, by the middle of November, his advance and success were at an end—the French became the assailants. Not only the Austrians, but also the Prussians, were defeated in all quarters; they could not withstand the immense numerical superiority, aided as it was by the maddening enthusiasm of the French, even in their strongly fortified redoubts at Hagenaew, Rheishoffen, Wrote, &c. From almost all of these they were driven at the point of the bayonet. Generals Hoche and Pichegru directed these wonderful achievements of the French. The campaign terminated in this quarter by the reduction of Spires and Fort Louix.

We have already alluded to the means by which the French armies were supplied with such a great numerical superiority, as to compensate, in some degree, for their want of experience and discipline: it will now be proper to explain them. As the Convention had completed the business for which they had been elected, viz., the formation of a constitution, they ought to have dissolved themselves; but under the pretext, that, in the state of France, their dissolution, and the election of a new assembly, might be dangerous, the Mountain party, which was still triumphant, determined that it should continue till the end of the war. They also succeeded in establishing what was called a revolutionary government, the principal engines of which was the committee of public safety. This superintended a number of inferior committees; and united in itself a wonderful degree of secrecy, dispatch, skill, and energy. It corresponded with all the Jacobin clubs throughout France, and sent commissioners, with unlimited powers, into all parts of the kingdom. It is evident that this form of government possessed wonderful means of carrying all its measures into complete effect; and, as its members were actuated by one sole motive—that of establishing their peculiar principles—these means were never neglected through inattention, or sacrificed to interest. In short, at this period, the whole population of France, with all its corporeal and mental powers, stimulated by the most wild and energetic enthusiasm, was directed by a body of men, who knew all the resources of the state, and who exercised their unlimited and almost unquestioned authority, with a degree of talent, vigilance, secrecy, activity, and zeal, never perhaps before combined. They were despotical, not less by the power which they actually possessed, than by the feeling which actuated France; for such was the abhorrence of seeing their country overrun by foreigners, such the desire of rendering what they conceived to be liberty triumphant, that the people almost offered themselves to the operation of those measures, which, with different feelings, and under different circumstances, they would have opposed as arbitrary and tyrannical. Thus the decree for placing France in a state of requisition, by which all unmarried citizens, from 18 to 25, were ordered to join the armies; while the married, the aged, and even the women and children, were to be employed in various ways in the service of their country, by forging arms, making tents and clothes, attending the hospitals, preaching hatred against the enemies of the republic, &c. was not opposed; so far from this, it produced all the effects which the committee of public safety, (from which it originated,) anticipated and expected.

The Mountain party having thus succeeded in raising the whole population of France against their enemies, and in securing victory by the numbers and enthusiasm of the armies, resolved to destroy the Queen and the Girondist party. Against the former accusations were brought so abhorrent to human nature, that even the most depraved
of the Mountain party were shocked at their tendency; after a mock trial, she was executed on the 16th of October. On the 30th of the same month, Brissot and 20 others of his party were executed; and the Duke of Orleans, who united perhaps a greater degree of personal and political depravity, than any man with whom the revolution has cursed France, was afterwards put to death, by that very party whom he had materially contributed to bring forward to serve his own purposes; and who now accused him of having aspired to the sovereignty from the commencement of the revolution.

As soon as the Mountain party had got rid of their opponents, they abandoned themselves to the most extravagant and most dreadful excesses. It seemed, in their mad and blind rage for innovation, as if they thought they could utterly alter, not only the constitution of society, but also the very structure of the human mind; and that they were resolved not to rest from their labours, till they had peopled France with a race of beings devoid of every feeling, principle, or habit, which can dignify or console mankind. On the 7th of November, Gobet, archbishop of Paris, with several other clerics, renounced the Christian religion in the hall of the Convention; and a decree was afterwards passed, that the only French deities should hereafter be Liberty, Equality, and Reason. The Parisians, however, were not so utterly profligate as to go along with the Convention in this respect; and Robespierre increased his popularity, by supporting religious worship.

In the beginning of 1794, the proposition of the allies provisionally to acknowledge the French republic, was rejected by the Convention. Possessed of such an immense machine as the whole population of France, which they wielded at their pleasure with most wonderful talent, and which they had already seen produce the most astonishing effects, it was not to be supposed that, in the moment of victory, the Convention would be disposed to treat with the allies, on the ambiguous condition of provisionally acknowledging the republic. Resolved therefore to persevere in the war, and having completely succeeded in recruiting the armies, the Convention turned their thoughts to the state of the finances. Soon after the commencement of the revolution, paper money, called assignats, had been issued; but as these had suffered depreciation, both from the uncertainty with respect to the fate of France, and from the immense issues of them, a law was passed establishing a maximum. This, however, it was soon discovered, increased the evil; it then became necessary to support the value and credit of the assignats, by the sale of the lands belonging to the church, and to the emigrants and persons condemned by the revolutionary tribunals. The churches were plundered of their gold and silver; even their bells were melted and cast into cannon. In order still further to supply the want of money, the personal labours of almost all classes were put in requisition. The materials for making gunpowder were perfected and supplied by the chemists; immense numbers of muskets and cannon were manufactured and cast. The whole agricultural produce of the country was seized by the government, who distributed it to each district according to its population.

Yet these very men, who seemed to have but one soul, when they acted for the defence of France, were divided into two most implacable parties. Robespierre was at the head of one; Danton of the other. Robespierre triumphed, and by the middle of April all his most active opponents had suffered death. His own fate, however, was not far distant; for, on the 27th of July, several members of the Convention whom he meant to have sacrificed, (among whom the most enterprising was Tallien,) accused him of tyranny: his arrest was decreed, and on the next day he was seized and executed. To him the Moderate party, as they were termed, succeeded; who, at the same time, that they stopt short of his atrocities, were undoubtedly inferior to him in talent, activity, and vigour; so that had not the great machine of the army been so admirably constructed, and so well supplied by Robespierre and his party, it must have fallen in pieces, or at least worked with diminished effect under his successors.

The allies being now convinced that the French not only could bring into the field larger armies than they expected; but that their generals possessed a very considerable degree of skill, and their troops steadiness and discipline, as well as enthusiasm, prepared to open the campaign of 1794 with such a force, and on such a plan, as, in their opinion, could not fail to render them generally and permanently victorious. Their force amounted to upwards of 180,000 men, consisting of Dutch, Germans, and English, divided into six armies; and their plan was, by getting within the frontier towns of France, to cut off their enemies from the interior. At first they met with some success; but the numbers which the decrees of the committee of public safety poured into the French armies, and the enthusiasm and ardour with which these raw troops were inspired, in a short time not only deprived the allies of the fruits of their victories, but obliged them to act entirely on the defensive.

Pichegru, especially, was eminently successful in mastic Flanders: Ypres surrendered to him, Charleroi was taken by Jourdan, who afterwards defeated the Austrians at Fleurus. These misfortunes compelled the allies to retreat in every direction; and the French beheld themselves advanced, victorious, to the confines of Dutch Flanders. On the Rhine, their success was equally great, and from the same causes: before the end of July, the Palatinate was in their possession. In the battles by which these conquests were achieved, they indeed lost immense numbers of men; but their leading principle was to bring superior forces every day till their object was accomplished; and thus acting on their enemies with a body, not only of greater weight, but of more rapid motion, they bore down all opposition.

The only cases in which they were unsuccessful this campaign, were in Corsica, and in their rencontre by sea with Lord Howe; the circumstances of both of which have been detailed in the History of Britain.

From the pause which the French army made, when it had advanced to the confines of Dutch Flanders, it was at first supposed that they did not mean to invade the United Provinces; but after a short pause, Pichegru advanced, and the allies retreated before him, first across the Meuse, and afterwards across the Rhine. On the 7th of November, Nimyeguen was occupied by the French, when they again paused in the career of victory. On the borders of Spain they were equally successful; the Spaniards were unable to stand before them, and the greater part of Navarre fell into their power, while, on the east side of Spain, Catalonia, by the conquest of Roses, was left totally undefended.
It is now time to look to Paris, at once the scene of constant intrigue, and the mutual massacre of parties, and the source whence all the victories of the army flowed. The Jacobins, though defeated, were not dispirited or inactive; they formed a most dextrous plot to regain their power; and this plot, as usual, was to be carried into execution in Paris, for whose sake Paris ruled the kingdom, and in the most profligate districts of Paris, for hitherto whoever ruled there, ruled the capital. The hall of the Convention was surrounded, on the 20th of May 1793, by immense numbers of abandoned and desperate women, who demanded bread, and the constitution of 1793; and the members were compelled to retire, till General Hoche with the military, dispersed the insurgents. The Jacobins, however, returned to the charge in the evening; and by pointing some pieces of cannon against the hall of the Convention, intimidated the members into a promise that bread should be supplied, and the constitution of 1793 restored. The troops again came to the relief of the Convention; and, by attacking the suburb of St Antoine, the great focus of rebellion, they succeeded in reducing the insurgents, and in restoring the authority of the Convention. In the south of France, where the Jacobins also endeavoured to regain their power, they were not more fortunate; so that the Convention might have established themselves firmly, and they became possessed of that commanding talent and energy, which the state of France, both at home and abroad, at that time, imperiously demanded. But they were deficient in these respects; and their deficiency they were anxious to compensate, by the establishment of a new constitution. The plan of this constitution was laid before the Convention, by the committee appointed to frame it, on the 23d of June. According to it, the legislature was to be composed of two assemblies; and the executive power was to be entrusted to five persons, who were to be called the Executive Directory. This plan was not received with much approbation at Paris; and an especial provision made by the Convention, that at the approaching election, the electors should be bound to return two-thirds of the present members, or, if they did not, that the Convention themselves might fill up the vacancies, gave very great dissatisfaction. In this emergency, the Convention endeavoured to strengthen themselves against the citizens of Paris, by an union with the Jacobins; and by this union, and the assistance of the troops in Paris, which were placed under the command of Barras, Brune, and Bonaparte, the refractory citizens were compelled to submit to the Convention; but the consequence was, that the Jacobins regained their ascendency.

On the 27th of October, the Convention was dissolved, and the new legislature began to act. Their first measure was the election of the Executive Directory. Sieyes, Barras, Recubil, La Reveillere Lepaux, and Letourneur de la Manche were chosen. Sieyes, however, declining the honour, Carnot was appointed in his place. All the members of the Directory except La Reveillere Lepaux, had been connected with the Mountain party.

At the commencement of the campaign of 1794, the King of Prussia had received a subsidy from Britain, on condition that he brought into the field an army of 60,000 men; but as this army never arrived, it was suspected that he was about to make peace with France. This suspicion was confirmed; for on the 20th of April, 1795, a treaty of peace with him was ratified by the Convention. Shortly afterwards, the Kings of Sweden and Spain, and the cantons of Switzerland, also concluded a peace with France; and towards the end of August, several of the German princes followed their example. The rest were on the point of acting in the same manner, when victory began to desert the French standard.

Before this reverse, however, the military successes of the French had been very great. We have already mentioned, that, after the reduction of Nineguen, their army halted in its career of victory. It is probable that they would not have invaded the province of Jutland at this season of the year, (the winter of 1794-1795) had not the frost, setting in with uncommon severity, opened for them a safe and easy passage over the ice of those very rivers and lakes, which it was hoped would have served as a secure protection. The allies in vain attempting to oppose their progress, they took possession of Amsterdam, without resistance, on the 16th of January 1795. They were well received by the people, and increased their influence and popularity by the abolition of the Statholdership.

Soon after this conquest, the Diet of Ratisbon seemed disposed for peace. The allies, instead of overrunning and dividing France, as they had planned and expected, beheld the republic increased by an additional population of nearly 14 millions; while in the course even of the campaigns of 1794 and 1795, and before the conquest of Holland, the French had taken 2000 pieces of cannon, and 60,000 prisoners. The wish of the Diet, however, notwithstanding these wonderful successes of the French, and the probability that they would continue, was not met either by Britain or Austria. The former was still successful by sea; and hoped, by nourishing and supporting the royalist party in La Vendee, to accomplish that which the allied army had failed in effecting; but the most disastrous expedition to Quiberon extinguished her hopes in that quarter.

Austria directed her efforts with more wisdom. By the middle of June, the French were in possession of the whole left bank of the Ilbine, except Mentz. In August, Jourdan crossed this river, in order to besiege Mentz; while Pichegru succeeded in gaining possession of Manheim. The Austrians having been driven back, the siege of Mentz was begun; but Jourdan was soon obliged to give it up, in consequence of a defeat which Pichegru experienced from General Wurmser. It was now necessary for both the French armies to recross the river; and after they had effected this, and the Austrians had recovered Manheim, an armistice for three months was agreed too.

In the mean time, the Directory and the Jacobins were continually at variance, and, as usual, each endeavoured to enlist the citizens of Paris in their favour. The more respectable classes were decidedly inclined to support the directory; but the mob, and the Legion of Police, as they were called, consisting of 10,000 men, were as zealous for the Jacobins. Relying on these, the latter attempted to carry into execution a plot, according to which, the members of the Directory were to be murdered, and a new directory and legislature appointed from among the most violent of their own party; but the plot was discovered, and the principal agents in it arrested. On the 9th of June, this year, the Dauphin died in the temple; and his sister was soon afterwards delivered up to the Emperor of Germany, in exchange for the commissioners, whom Dumourier had sent prisoners to the Austrians, and for two Frenchmen, who had been seized on their way to Turkey.

As the campaign of 1795 had terminated unsuccess-
fully to the French on the Rhine, the Directory resolved to exert their utmost endeavours to open that of 1796, in such a manner as would restore their superiority, and regain their conquests. But when they began to examine the means that they possessed for recruiting the armies, and supplying them with the necessary provisions and stores, they found a lamentable deficiency of money. The assignats were excessively depreciated; nor could their credit be any longer supported by the most severe decrees, while an increased issue only augmented the depreciation. It was therefore resolved, on the 25th of March 1796, to dispose of the remainder of the church lands; but it seems not to have entered into the thoughts of the Directory, that, as the purchase of them would be paid for in paper money, the actual proceeds would amount to very little. As soon as they found this to be the case, the legislature decreed that one-fourth of every purchase should be paid in cash; and this almost immediately put an entire stop to the sale of the property, and consequently to this source of revenue.

Notwithstanding this disappointment, the French prepared to open the campaign with an immense force. The army of the Sambre and Meuse, under the command of Jourdan, was stationed at Dusseldorf and Coblenz; Moreau had the command of the army of the Rhine and Moselle, on the upper Rhine; and Bonaparte, who had been brought into notice during the disputes between the Convention and the Parisians, in the preceding year, had the command of the third army on the Italian coast, from Nice to Genoa. The wonderful advantages of Bonaparte in Italy, and the defeat of Jourdan, and retreat of Moreau, in Germany, render this campaign extremely interesting and important.

As soon as Bonaparte assumed the command, he threatened Genoa. This induced Beaulieu, who commanded the Austrian troops, to resolve on the attack of the whole French line; but the attack being unsuccessful, and part of his army out-flanked by the French, he was compelled to retreat. Bonaparte immediately followed up his advantage. On the 14th of April, having broken in between the Piedmontese and the Austrians, he defeated the former; and, by his subsequent success over them, compelled the King of Sardinia to purchase peace, by the surrender of Savoy, Nice, &c. The Austrian general, being deserted by his ally, was now obliged to act on the defensive, and, for this purpose, took up a strong position behind the Po. But Bonaparte, instead of crossing that river at Valentia, which Beaulieu expected he would do, marched into the dominions of the Duke of Parma, and passed it at Placentia. The Austrian general being thus forced to abandon the Po, retreated to the neighbourhood of Lod, in the Milanese. The bridge, at this place, over the Adda, was defended by 30 pieces of cannon, which rendered its passage so very formidable, that all the officers whom Bonaparte consulted, were of opinion it could not be forced; but the grenadiers expressing their willingness to undertake the enterprise, were formed into a close column, and reached the middle of the bridge unperceived, in consequence of the smoke of the cannon. Here they were mowed down in great numbers, and began to hesitate; but they were animated to press on by their officers, and succeeded in gaining possession of the bridge. The retreat of the Austrians having been protected by a body of Neapolitan cavalry, their loss was not so great as that of the French. The conquest of the Milanese, and of Ferrara, Bologna, and Urbino, were the fruits of this victory, the Austrians retiring into the bishopric of Trent. Naples and Tuscany fought and obtained peace. The siege of Mantua was the next object of the conquerors; but they were drawn from it by the re-advance of the Austrians under General Wurmser, who had been appointed to supersede Beaulieu. This general was not more successful than his predecessor; and being obliged, after repeated defeats, to retire to the Tyrolean frontier, Mantua was re-taken. After a month's retreat, the armies again tried their strength, and the Austrians being again defeated, the victors took possession of Trent. They did not, however, at this time, long keep possession of this district, for Wurmser; by his manœuvres, drew them out of it; and though he sustained another defeat, yet, in his retreat, he succeeded in encouraging the garrison of Mantua, by throwing himself into that place. The Austrian army was now placed under the command of Alvingi, who, at first, was partially successful, but was at length driven across the Brens by Bonaparte. Mantua, however, still held out at the end of the year 1796.

The armistice in Germany terminated on the 31st of May. In consequence of the success of the French at the commencement of this campaign, the Archduke Charles left the Palatinate, to force Jourdan down the Rhine. In this he succeeded; but in the mean time, Moreau had crossed that river at Kehl, against him therefore the Archduke thought it proper to advance; and Jourdan, taking advantage of this, again crossed the Rhine, and afterwards the Lahn, and gained possession of Frankfort. The Archduke, apprehensive that Jourdan and Moreau would form a junction, resolved to attack the latter before it took place; but Moreau anticipated him, and the Austrians were compelled to retreat. Their army also, which was opposed to Jourdan, retreated, keeping up, however, a communication with the main army under the Archduke. The line of their retreat was through Swabia; and, by the end of August, the three republican armies, under Moreau, Bonaparte, and Jourdan, were possessed of the whole country from the frontiers of Bohemia to the Adriatic, with the exception of a part of the Tyrol. The German princes took the alarm, and many of them made peace with France. Had Bonaparte, at this period, been able to have crossed the Tyrolean, and reached the Danube, the Emperor must also have submitted to whatever conditions the French chose to dictate.

The Archduke Charles being strongly reinforced, endeavoured to oppose the advance of Moreau; but not succeeding, he crossed the Danube, and attacked Jourdan, leaving part of his army as a check on Moreau. Jourdan was now under the necessity of retreating, till, by the middle of September, he arrived at Coblenz and Dusseldorf, from which places he had advanced at the beginning of the campaign.

Moreau, in the mean time, endeavoured to drive before him the part of the Austrians which were left to watch him; but they, having been reinforced, he could not penetrate beyond the Iser. His communication with Jourdan was now completely cut off, and for some weeks he was ignorant of his fortune or movements. As soon, however, as he learned that he had been compelled to retreat, he was sensible that it was absolutely necessary for him to retreat also. In order to deceive the general who was opposed to him, he at first moved as if he meant to penetrate further into Austria; and having thus compelled his adversary to fall back, he began his retreat between the Danube at Ulm, and the
Lake of Constance. On his rear the Austrian general hung incessantly: his route through the Black Forest was occupied by numerous bodies of Austrians and armed peasantry, while his right flank was harassed by another army of 24,000 men. Notwithstanding the extreme difficulties of this critical situation, he continued his retreat in the most excellent order, and actually more than once turned upon and defeated the army that was pursuing him. The dreadful passage of the valley of Hell, overhung with lofty mountains, and in some places only a few fathoms broad, was forced by the centre of his army in a mass, while the wings opposed the Austrian armies that hung on his rear and flanks. On the 15th of October he arrived at Friburg; but he was soon afterwards forced by the Archduke to abandon all his positions on that side of the Rhine, except Kehl. This place also the Archduke was resolved to reduce; but not being able to succeed, and the French, finding their whole frontier exposed, the latter evacuated it in the beginning of 1797.

The first object of the Austrians in 1797, was the relief of Mantua. General Alving's army was upwards of 40,000 strong. At first they were so successful against a division of Bonaparte's army, that their immediate capture was expected. As soon as that general was informed of their critical situation, he hastened to their relief. On the 14th of January, a most obstinate battle took place at Rivoli. The centre of the French was on the point of giving way, both their flanks were surrounded, and the defeat of Bonaparte seemed certain, when, by a masterly manoeuvre, he completely changed the fortune of the day, penetrated the right wing of the Austrians at various points, and threw them into such disorder, that 4000 of them threw down their arms. On the following day, 6000 more were surrounded and taken prisoners. Bonaparte now hastened to meet that part of the Austrian army which was threatening the lines of the blockade, and succeeded in capturing the whole of them. The defence of Mantua being now hopeless, General Wurmser capitulated.

The humiliation of the Pope was the next object of Bonaparte. The forces of his Holiness were soon subdued, and he was compelled to sign a peace, dictated by the French general.

The French government having failed in their attempt to reduce the Emperor to submission by the campaign on the western side of Germany, resolved to penetrate into his hereditary dominions on the side of Italy. They, therefore, sent strong reinforcements to Bonaparte. On the other hand, the Archduke Charles took the command on the southern frontiers of Austria; but, instead of waiting for the enemy in the mountains, he was directed by the council of war at Vienna to descend into the plains, and defend the rivers. The consequences of this absurd plan were fatal to the Austrians, who were driven from all their positions, and lost their principal magazines. In fifteen days Bonaparte took 20,000 prisoners, and effected the passage of the Alps. His way to Vienna was now open; but not insensible of the danger to which even his successful progress had exposed him, he wrote to the Archduke on the 31st of March, proposing peace. The latter replied, that he had no authority to treat; and, in the mean time, the inhabitants of the Tyrol rose en masse. Neither they, however, nor the regular Austrian armies, were able to stop the progress of the French, who, on the 2d of April, forced the strong defiles between Friesach and Newark. This success, and another defeat which the Austrians sustained on the 10th, induced the Emperor to treat for a peace; and on the 19th a preliminary treaty was signed, by which the French were to retain the Austrian Netherlands, and the Milanese, Mantua, Modena, and Bologna, were to be formed into one state, and to be called the Cisalpine Republic. This was followed by a definitive treaty at Campo Formio, which confirmed these articles, and gave the French the Venetian islands in the Levant. While these operations were going on in the south of Germany, Generals Hoche and Moreau not only prevented the Austrians on the Rhine from sending reinforcements against Bonaparte, but even gained several advantages over them, and pursued part of them towards the Danube.

In the midst of these wonderful successes, there were still divisions and disputes among the members of the government at Paris. A decided majority of both councils, as well as two members of the Directory, were of the Moderate party; but, in consequence of some violent discussions respecting finance, and the restoration of the property of the emigrants, the legislative and executive branches became professes enemies to each other. General Hoche, with a division of the army, was brought into the neighbourhood of Paris by the Directory; and Augereau was sent for from Italy by the opposite party. The latter surrounded the Thilleries, and made Pichegru and twelve more chiefs of the opposite faction prisoners; Carnot escaped, but Barthelemy was put under arrest. Shortly afterwards the councils, in a most arbitrary and tyrannical manner, voted the transportation to Cayenne of 53 of their own members, and 12 other persons, among whom were Barthelemy and Pichegru. In the room of the displaced directors, the legislature chose Merlin and Francis de Neufchateau. About this time the negotiation with England, conducted by Lord Malmesbury, failed. France was now at peace with all the powers of Europe except Great Britain. The transactions that took place between them are recorded elsewhere; we shall only state two more confined ourselves to the conduct of the French towards the Pope, Switzerland, and Naples, during the year 1798. At Rome, some disturbances happened between the French party and that portion of the inhabitants who remained faithful to his Holiness. In the course of these disturbances a French general was shot, and Joseph Bonaparte, who was there as plenipotentiary, demanded his passports, and returned to Paris. The Pope, alarmed, solicited the protection of Vienna, Spain, Naples, and Tuscany, but they would not interfere. General Berthier with an army marched against Rome, subverted the dominion of the Pope, and proclaimed the sovereignty of the Roman people. Ever since the first successes of Bonaparte in Italy, the French had instructed their generals to demand, or take by force, all the most valuable paintings, antiquities, &c.; but on the capture of Rome, these, instead of being sent to Paris, as the spoil of other cities had been, were sold on the spot.

In Switzerland, French principles had been successfully propagated; and early in 1798, the Directory resolved to take advantage of this circumstance, and reduce this country. A pretence similar to that which they had eagerly embraced at Rome occurred, and was as eagerly embraced: the Pays de Vaud was invaded, and by the end of January reduced. The senate of Berne now prepared for an unequal contest; but they soon found, that not only a large portion of the inhabi-
tants of this canton, but also of the army, were disaffected. Notwithstanding this, they imprudently decreed the rising of the people in a mass: the people, indeed, rose, but they dissolved the government. They were, however, by no means willing, that the French should interfere in their disputes, and therefore offered terms to them, which were rejected. The enemy continued to advance; the Swiss in vain opposed them, and injured their own cause by murdering their officers, after a complete defeat that they suffered early in March. Berne capitulated, and most of the other cantons followed its example. A new constitution was framed at Paris for this country; but the inhabitants of the smaller and more democratic cantons refused to accept it, and took up arms. At their head was Aloys Reding, a man of superior purity of patriotism and talents; but all his efforts were unavailing, the confederacy being soon dissolved by the arts and the overwhelming power of the French. Scarcely, however, had an accommodation taken place, when new commotions arose, which partook of the madness of despair; even the women rushed into the midst of the battle; and the robbers and mountaineers pressed the Frenchmen to death in their arms. The French retaliated, by the infliction of every species of cruelty that they could devise; and, after a short but desperate contest, overthrew the independence of Switzerland.

The King of Naples having impudently placed so much confidence in the consequences of the victory of the Nile, as to declare war against the French, and to advance to the re-conquest of Rome, the Directory resolved to crush him. This was an easy task; the Neapolitan troops were few in numbers, and excessively ill disciplined; they fled before, or weakly opposed, a comparatively small number of French. Rome was recovered; Gaeta surrendered. General Mack, who commanded the Neapolitan troops, being driven from Capua, and not being able to depend on his army, surrendered himself, and the officers of his staff, to the republican general. A short time before this, the King of Naples, having embarked for Sicily, the loyal population of that city, and the peasantry of the adjoining districts, attacked the enemy, but were defeated, the metropolis submitted to the French yoke.

Towards the end of 1798, there were signs of the renewal of the confederacy against France. The Russians had already commenced hostilities in the Levant, soon after they heard of the victory of the Nile; and being subsidized by Britain, they marched an army of 45,000 men to the confines of Germany. Austria, however, was at first afraid to engage in a new contest; but not giving a satisfactory answer to the French, who declared, that the entrance of the Russian troops into Germany would be considered as a declaration of war, the Directory, on the 13th of March 1799, ordered the commencement of hostilities, not only against the Emperor, but also against the Grand Duke of Tuscany. At the commencement of this war, the prospects of the French were very flattering, and they possessed many advantages which they had not during the previous contest. They were very powerful on the Rhine, by the occupation of Dusseldorf and Mainz. They also had the command of Switzerland, and all the strong places in the north of Italy. Their first object was to obtain possession of the Grison country, that a communication might be preserved with Germany. Massena advanced for this purpose; while Jourdan, who commanded on the upper Rhine, advanced on his side, in order to meet him. Massena soon reduced the Grisons; but he was defeated in his next enterprise, the reduction of the post of Feldrich, which was held by the Austrian General Hotze. The Austrians, however, could reap little advantage from this success, but deemed it prudent to retreat into the Tyrol. The Archduke was opposed to Jourdan, and he was more successful; the French general being obliged to retreat with considerable loss. Jourdan was soon afterwards removed, and Massena appointed to command his army.

But the most important scene of operations this year was in Italy, where the Austrians were successful in several engagements, even before the junction of the Russians. This event took place about the beginning of April, and Suwarow, who assumed the command of the combined army, resolved to pursue a bold plan of operations. Moreau was opposed to him, but the Russian general deceived his adversary, drove him from his entrenchments on the Adda, and obliged him to retreat to Pavia, after having suffered a dreadful loss. Moreau shortly afterwards gained some successes over the whole part of the Russian army, but Suwarow, advancing, was obliged to continue his retreat. At this crisis, Macdonald, who commanded the French army in the south of Italy, pushed forward for the purpose of joining Moreau. But he found that it would be previously necessary to attack the allies; and Moreau endeavored, by circulating a report that he was about to receive reinforcements, to withdraw the attention of Suwarow from Macdonald. The latter began his operations on the 12th of June; and succeeded so far as to enter into Parma on the 14th; but his progress was arrested on the 17th. As soon as Suwarow was informed of his advance, he left Turin at the head of 20,000, and came up with him on the banks of the Tadone: for three days, there was a succession of desperate battles; and the victory was at last obtained by the Russians, in consequence of General Kray, who commanded the army besieging Mantua, arriving, in direct opposition to his orders, with large reinforcements. Suwarow was indefatigable in his pursuit of the beaten army, and having surrounded their rear guard, it was the only surrender: the remainder took refuge in the Apennines and in the Genoese territory. Moreau, in the mean time, was victorious over the Austrian General Bellegarde; but his victory availed little, in consequence of the success of Suwarow, and the Italian fortresses fell into the hands of the allies. Soon afterwards, in consequence of a political change in Paris, Joubert was ordered to supersede Moreau, who, however, continued in the army as a volunteer. It was the plan of Joubert to bring Suwarow to battle as speedily as possible; and being reinforced by the remains of Macdonald's army, he succeeded in his plan at Novi, on the 15th of August. Scarcely had the engagement commenced, when Joubert was killed, and Moreau assumed the command: the victory was doubtful, till it was decided by the right flank of the French being turned. This division immediately fled, and the rest of the army joined in the retreat, which they continued till they took up a strong position in the Genoese territory. The surrender of Tortona was almost the only result of this victory.

The Directory, thus unsuccessful in Italy, resolved to make Switzerland the grand scene of operations, and, to adopt a new plan. In the month of August, Massena had the command here of 70,000 men; and being superior to the Archduke, whose position he threatened, Suwarow marched to his relief. But the ca-
neal Kray; but the latter was fettered by the orders
which he received from the council of war at Vienna,
whereas Moreau refused to act according to the instruc-
tions sent him by the Chief Consul, except where his
own judgment and observation convinced him they
were wise and practicable. The plan of Moreau was
to cross the Rhine; in this he succeeded, and drove
Kray before him as far as Ulm: here he fortified his-
self; but Moreau, manoeuvring in such a manner, as to
threaten to cut him off from his magazines, the Aus-
trians were obliged to fight at Hochstatt. The French
were victorious, and the Austrian general, after in vain
endeavouring to oppose the enemy again at Newburg,
was obliged to fall back to Lugolstadt. The electorate
of Bavaria was conquered: the hereditary dominions of
Austria were threatened, and at Vienna the populace
demanded peace.

The affairs of Austria were not more promising on
the side of Italy. The army of reserve that had been
collected at Dijon, marched, as soon as the campaign
opened on the Rhine, towards Italy. The First Consul
joined them near the Lake of Geneva; and the passage
of the Alps was immediately prepared to be under-
taken. The difficulties only served to stimulate the
ambition, the energy, and the talents of Bonaparte.
The trunks of trees were hollowed into the forms of troughs,
that the cannon might slide along in them; the gun-
carriages were conveyed on sledges, and the wheels on
poles. Their passage was over Mount StBernard, which
the men could only ascend one by one, moving with
the utmost caution. The descent was still more dan-
gorous; but so admirably were the measures of Bona-
parte planned and executed, that scarcely any lives
were lost; and none of the cannon or provisions were
left behind. Thus was effected the passage of a nume-
rous and well-appointed army over the Alps—an en-
treprise so extraordinary, that the Austrians, from a
firm conviction that it was absolutely impracticable, ne-
ever thought of opposing it. Aosta, the fort of hard,
Ivry, Romagno, and Vercelli, were taken. The Tes-
sino was crossed; Milan entered without opposition;
valuable magazines were captured at Pavia; and Pla-
centia fell into the possession of Bonaparte, who, by
his sudden and unexpected appearance, and by his sub-
sequent masterly manoeuvres, completely outgeneraled
Melas.

He did not arrive, however, in time to relieve Genoa; fall of
for Massena, after one of the most obstinate defences
recorded in history, during which 15,000 of the inha-
bilants are said to have perished by disease and famine,
was compelled to surrender to the Austrian and Bri-
tish commanders on the 5th of June. As soon as Geno-
a fell, Melas dispatched General Ott with 30 batta-
lions to check the progress of the French, who hitherto
had not penetrated farther than Piedmont; but that
general having suffered a dreadful defeat at Mon Abello,
Melas collected his whole force between Allesandra
and Tortona. Here, on the 14th of June, was fought
the battle of Marengo: for nine hours the Austrians
were victorious; but an imprudent or unskilful move-
ment of General Melas, which was instantly taken ad-
vantage of by General Dessaux, who made a vigorous
charge with a body of fresh cavalry, turned the fate of
the day. The victory was purchased by the death of
Dessaux, to whose memory due honours were paid by
his grateful countrymen.

The Austrian general, intimidated by his defeat, re-
quested a truce, which was granted on condition that
Genoa should be surrendered, as well as the principal
fortresses in Piedmont and the Milanese. General Kray
was desirous of extending this armistice to Germany,
but to this Moreau would not consent; and two battles
were fought without much advantage on either side.
The French, however, persevered in their attacks, and
at length opened themselves a passage into the heart of
Bavaria. At this period, Count St Julian arrived with
proposals of peace from the cabinet of Vienna, and the
armistice was extended to Germany. This armistice
did not lead to peace, for the Emperor, encouraged by
Britain, resolved to try the chances of another cam-
paign: hostilities therefore recommenced in the autumn.
At first Moreau was surprised by the activity, and near-
ly defeated by the impetuosity of the Austrians; but
the Austrian general abandoning his strong position,
the fatal battle of Hohenlinden was fought on the 8th
of December. In this battle, the Austrian centre was
pierced, and their wings thrown into confusion; their
loss was dreadful; their route complete. Pushing into
Upper Austria, the victorious French reached the banks
of the Ems. The cabinet of Vienna was alarmed; the
Archduke, who had been deprived of the command of
the army, was recalled; but all his skill and efforts were
in vain; and the Emperor mournfully saw that peace
alone could save him from utter destruction. The	

treaty of Luneville was the consequence.

Soon after Mr Addington became prime minister of
Britain, a negotiation was opened with France, which
terminated in the peace of Amiens, on the 22d of
March 1802.

At this period, the territories of the French republic
were very extensive; and her power extended even be-
yond these territories. With France, as it existed
previously to the Revolution, was incorporated the Nether-
lands, and that part of Germany which lies on the west
of the Rhine, as well as Geneva, the duchy of Savoy,
and the principality of Piedmont. The Dutch repub-
lic was completely subject to the will of France;
the Swiss possessed scarcely a larger portion of national
independence. Spain, under the appellation of an ally,
was in fact a vassal state. The Cisalpine republic was
completely under the yoke of the First Consul, who
had been appointed its President for ten years. This repub-
lic not only comprehended the Milanese, but also a
considerable part of the Venetian territories, the duchies
of Mantua, Modena, and Parma, and some of the dis-
tricts which had belonged to Rome. A vassal king gov-
erned Tuscany, which was thus in reality placed under
the power of France; and the Ligurian republic was
equally subservient. Over all this immense tract of
country, therefore, extending from the Ems to the
Strait of Gibraltar, and from the Atlantic to the Adri-
tic, did Bonaparte, as First Consul of France, exercise
an absolute sway.

But his power in fact was not limited, even when this
immense territory was included within it. The Emperor
of Germany and the German Princes had suffered so
much from French invasion, that they durst not ques-
tion the authority of Bonaparte; the King of Prussia
had only displayed his devotion to his wishes, as
well as an unjust regard to his own interest, by the
seizure of Hanover; and the new Emperor of Russia
was too recently and mysteriously fixed on the throne,
to come forward against the power of France.

Britain alone, therefore, which had so long, and with
such wonderful perseverance and sacrifices, resisted
France, came out of the contest untouched in her na-
tional independence.

One of the first measures of Bonaparte, after he had
placed France at peace with all her enemies, was the
re-establishment of the Catholic religion. For this pur-
pose, a concordat or convention was concluded between
him and the Pope, of which the following are the most
important articles. No bull, &c. of the court of Rome,
to be circulated or put in force without the authority
of government; No nuncio, legate, &c. to exercise his
functions in France, without the consent of the govern-
ment: No person to be named a bishop who is not a
Frenchman: No bishop to quit his diocese, without
leave from the First Consul: No festival, with the ex-
ception of the Sabbath, shall be established without
the permission of government. The nuptial benediction
shall be given to those only, who shall prove in due
form that their marriage has been contracted before a
civil magistrate. All religions were tolerated and pro-
tected, and special rules were laid down for their
guidance.

By this concordat, Bonaparte gained great popularity
with the mass of the nation; and as he was almost ido-
lized by the soldiery, he experienced no difficulty in in-
creasing his power. When he was chosen First Consul,
ten years were to be the duration of his authority; he
was now, however, appointed for life, and the power
conferred upon him of nominating his successor. Short-
ly after this, his plans for another war began to de-
velope themselves. On the 21st of February 1803, a view
of the state of France was laid before the Legislative
Body and the Tribunate, the most interesting and im-
portant part of which related to the dispute with Bri-
tain, regarding the retention of Malta. The nature
and result of this dispute, we shall not here enter into,
as they, as well as the subsequent war, are fully nar-
rated in the History of Britain. As soon as Bona-
parte resolved on hostilities with Britain, he marched
an army into Osnaburgh and Hanover, and gained
possession of these districts without opposition. On
the 25th of April 1804, he was declared Emperor, by
a decree of the Tribunate of France, to the following
purpose.

When the national will (it was said) could manifest it-
self freely, it declared for the unity of the supreme power,
and the hereditary succession of that power. This desire
had been for a time extinguished by the tyranny of
the family of the Bourbons, and the nation were driven
to adopt a democratic form of government; from this
form, however, only the miseries of anarchy proceeded;
and the state was in the most extreme danger, when
"Bonaparte, brought back by Providence, suddenly
appeared for its salvation;" that the consulship for
life, and the power granted to the First Consul of ap-
pointing his successor, could not prevent internal in-
trigues; in order, therefore, to avoid them, and at the
same time to follow the example of all great states,
anient and modern, and to comply with the first wish
of the nation expressed in 1789, the magistracy ought
to be declared hereditary. This declaration the nation
now makes more strongly and generally than ever;
and her gratitude and affection point out Bonaparte,
from whom and his family France expects more than any
other, to the maintenance of the rights and liberties of the
people. That there is no title more suitable to his glory,
and to the dignity of the supreme chief of the French
nation, than that of Emperor.

Such was the decree of the tribunate, which was fol-
lowed by voting, "That Napoleon Bonaparte, the
First Consul, be proclaimed Emperor of the French,
and in that capacity be invested with the government of the French Republic." “That the title of Emperor, and the imperial power, be made hereditary in his family in the male line, according to the order of primogeniture.”

This vote was carried by acclamation, Carnot being the only person who spoke against its adoption. The Senate and the army followed the example of the Tribunal, intreating Bonaparte to become Emperor of France. Thus easily and tranquilly did Bonaparte obtain the object of his desires.

As he had been long married without children, he was allowed to adopt the children or grandchildren of his brothers, when they arrived at the age of eighteen, provided he had no legitimate children. On the failure of both legitimate and adopted heirs, the crown was to be enjoyed by his eldest brother Joseph, and his descendants; and, failing them, by his next brother, and his descendants, &c. The members of the imperial family were to be called French Princes, and the eldest of them the Imperial Prince. Every Emperor, within two years after he came to the throne, was to swear to maintain the integrity of the French empire.

Thus that revolution, which was begun for the express purpose of establishing a free government,—which, shortly after its commencement, destroyed the king and the monarchy, and during which the very suspicion of being attached to the royal cause exposed the suspected party to certain death, terminated in the establishment of a military despotism.

We have hitherto deferred entering into a development and explanation of the causes which produced, either directly or indirectly, or generally or partially, this revolution, as well as of the causes to which we ought to ascribe the rapid and total change in the nation, from an apparently strong and sincere attachment to liberty, to at least an acquiescence in military despotism; and of those causes which contributed to the astonishing, and almost unparalleled successes and victories of the French arms. All these we have hitherto deferred entering upon, in order that we might view them in connection with each other; for, in our opinion, these three events are intimately and necessarily connected, springing out of each other, as well as all of them, in some measure, originating from the same circumstances. We shall now consider them in their order.

1. With respect to the causes which produced the French revolution, either directly or indirectly, either partially or generally, in France, it may be proper to premise some general remarks on the causes which altered the character or fate of nations. Before philosophy had lent her aid to the lessons of experience and observation, so as to draw from them their legitimate consequences, it was supposed that the fate of a nation depended on the character and conduct of the leading individual or individuals in it; and when that character and conduct were pointed out and explained, it was taken for granted, that the particular circumstances in the national history, which had attracted attention from their extraordinary nature, were also sufficiently accounted for. But philosophy taught, that no individual can operate changes, or produce effects of an extraordinary nature, in any country, unless he act on materials suited to his purpose; and that, as he must have been formed by the prevailing spirit and habits of the nation on which he is supposed to operate, the very existence of such a character as his, is a proof that the nation was tending towards that change, which was solely attributed to the influence of his character and efforts. We must, however, guard against going into the extreme of this opinion; for there can be no doubt, that though favourable circumstances must pre-exist, before any individual can radically affect the character, or produce any great change in the fate, of a nation, yet, on the other hand, some thing ought to be ascribed to the influence of individual character. Perhaps a more striking proof of this cannot be exhibited, than what the history of Prussia affords us: During the reign of Frederic the Great, this kingdom stood high in the rank of nations in a military point of view. That the Prussians possessed the requisites for making good soldiers, is admitted; but it may surely be questioned, whether, if Frederic the Great had not been the character he was, Prussia would have gained the pre-eminence she did in warfare, or the advantages resulting from that pre-eminence. That this opinion is correct, the history of Prussia, after the death of this king, sufficiently proves: another sovereign, of a different character, or, more properly speaking, of different talents and habits, ascend the throne; Prussia immediately sank in the scale of nations. Perhaps the legitimate conclusion to be drawn, is, that in nations highly civilized and enlightened, in which almost every individual has an independent political existence, and regards himself as a component part of the government, individuals can do little or nothing except through the instrumentality of the nation, by conforming to its character, and employing its prejudices and feelings in the schemes which they are desirous to carry into execution; whereas in a nation rude, ignorant, and barbarous, in which the great mass of the nation have no conception that they have any right to interfere in the conduct of their governors, events are much more, though still not by any means entirely, under the influence and direction of individual character.

Let us now consider the revolution of France with reference to these observations, and the causes which have been supposed to have produced that event.

In the first place, much has been ascribed to the influence which the writings of such men as Montesquieu, Voltaire, Rousseau, Helvetius, &c. produced on the opinions and wishes of the French people; but it should be recollected, that on the mass of the people these writings could have little or no influence, as by few of them they were read, nor could they have been understood had they been read. The hypothesis that ascribes the French revolution to this cause, confounds two distinct circumstances; or rather supposes, that when it has accounted for one part of the phenomenon, it has accounted for the whole. The events of the revolution sufficiently prove, that, even at its commencement, it was indicated not more by a change in the character, opinions, and conduct, of the more intelligent classes of the French community, than by a change in the characters, opinions, and conduct, of the great mass of the people, on whom the writings of the philosophers could have had no influence. While, therefore, we may regard these writings as having prepared the way, in some degree, for the revolution among the higher and more intelligent classes, we ought not to consider them as being exclusively the cause, even with regard to them, and certainly as no means the cause with regard to the mass of the people.

Nearly the same remarks will apply to the second cause to which the French revolution has been attributed. It has been said, that by the return of the officers and soldiers who served in America, principles and feelings of liberty were spread over France, which, meet-
The causes which revolutionized the great mass of the people, are quite distinct from those we have just enumerated. When, indeed, the first symptoms of the Revolution became manifest, many thought it would not spread over the nation, when they reflected how ignorant the people were, how blindly and obstinately attached to old establishments, how passionately devoted to their monarch, and every thing that concerned him; and that, though oppressed by the nobility, and neglected by the government, they seemed quite insensible to the miseries of their condition, and exhibited more striking symptoms of content and happiness than nations much freer and more highly favoured. How then were such a people changed, and changed so completely, as to hear of the execution of their monarch with exultation? The cause when explained is very simple. The peasantry, though accustomed, were not utterly insensible to the tyranny of the nobles; nor could they be held with indifference, scenes of profligacy and wanton extravagance displayed at their chateaux, at the very time when their own cottages were the abode of misery and famine. Though utterly ignorant of the meaning of political liberty, they knew what was meant by being freed from the oppressions, taxes, and vexations to which they were subjected, and still more keenly did they enter into the prospect of having it in their power to retaliate on the nobility the evils they had suffered from them. In short, at the commencement of the Revolution, they received, or seized on power; and very naturally became attached to that event, from which such a blessing in their estimation proceeded. Had the Revolution only promised them political liberty, they would have regarded it with indifference; with them it would have found no supporters; but addressing itself to their passions and feelings, they rose in favour of it, and in their exultation, at their liberation from the oppressions under which they had long groaned, and at the ruin of those who had regarded their misery with indifference, or perhaps essentially contributed towards it, they forgot their loyalty, and beheld in their monarch only the chief of their oppressors.

We are now to consider the circumstances in which
the nation was placed, which allowed or encouraged those distinct causes to operate together with the fullest effect.

We have already noticed the embarrassed state of the French finances at the termination of the American war in 1789; and that the government, finding all their plans ineffectual towards the bringing them into order, were at last compelled to assemble the Notables. Thus were collected at Paris most of those men who were desirous of a change; and who beheld themselves in a condition, from the wants of the government, the appeal which had been made to them to suggest measures for the supply of those wants, and their own strength, to use their efforts for the accomplishment of their wishes. Their objects, indeed, might differ; for while some wished merely to curtail the power of the crown, in order to restore the privileges of the nobility; others wished to attack the power and privileges both of the crown and the nobility. Under these circumstances, it is evident, that the former was placed in a situation of great peril, and that the objects of the nobility were not so likely to be met with as those of the other party; since they had to concert their measures in such a manner as at the same time to act against the crown, and against that party. But in this view of the causes of the Revolution, the nature of the place, where those desirous of a change were assembled, must be taken into consideration. In countries, where the mass of the people have been long habituated to regard themselves as interested in the acts of the government, and privileged to express their wishes and opinions regarding those acts, it is impossible that the population of the capital, however numerous or intriguing, should possess an undue share of influence; but the case is different in countries where the people do not think themselves authorised or qualified to discuss the measures of their rulers, especially if the connection and communication between the capital and the provinces is by no means intimate, regular, and frequent. In such countries, the population of the capital gives the colour and tone to the feelings and actions of the population of the provinces; and whoever wields it, wields a machine, by means of which he may almost certainly succeed in overthrowing the government of the country. This was very strikingly the case in Paris. The merely from the political ignorance and bondage in which the people of France had long been kept, but also from the peculiar character of the population of the capital; in which, even before the Revolution, there was to be found a greater laxity of principles and conduct, and more intrigue, restlessness, and systematic depravity, than existed in any other capital of Europe. There was also in it a larger number of what are called men of letters, who would willingly lend their talents to the propagation and support of any doctrines, to the recommendation of any schemes or acts, however unjust or pernicious.

It is not to be wondered at, therefore, if all the parties in the Revolution aimed principally at gaining over the population of Paris, which, from its influence as the population of the capital of France, and from its peculiar fitness for being acted upon in such a state of things, could not fail to be of essential service to their views.

Those who first appeared as the leading actors in the tremendous drama of the French Revolution, were, it may be allowed, without any great stretch of candour, men who at least did not contemplate or approve of violent and unjust changes in the state; but at the same time it must also be urged against them, that they came to the task totally and lamentably unprepared for it; unprepared by their general ignorance of human nature—by their ignorance of the sound and practicable principles of government—and most of all, by their ignorance of their own unfitness, and of the total want of preparation in the French people, even for gradual and moderate reform. Thus ignorant, they roused and armed the worst passions of the multitude; they instilled into them a love of change, and they taught them their own power. The consequences were such as might be expected, when we reflect on the character of the population of Paris, on whom they at first setted, and who afterwards became the instruments of more daring and unprincipled leaders.

Still, however, it must be admitted, that it is difficult to trace the formation, or understand the real features of the characters of such men as Robespierre, Danton, Marat, &c. That they were almost unparalleled in cruelty; that they had no conception of the obligations of truth and justice, is too apparent: but these horrid qualities were strangely mixed with some species of patriotism; and even in the midst of unlimited power, they seem to have had little or no ambition, and certainly made no attempts to enrich themselves.

II. With respect to the causes of the wonderful military successes of the French, it appears to us that three causes principally contributed to these successes.

In the first place, long previous to the revolution, certainly as far back as the reign of Louis XIV. the French nation of all ranks and classes, the poorest and most oppressed equally with the richest and most highly privileged, have been distinguished by their love of glory, and by a hope, sometimes weak and evanescent, at other times strong and prevailing, but never totally extinguished, that their nation was destined for universal empire. This has been their predominant and characteristic passion; and this passion has been strengthened and encouraged by all the circumstances of the Revolution.

For, in the second place, there came in aid of this passion, the strong feeling of national independence, independent which all nations, even the most barbarous and enslaved, possessed in a greater or less degree. We have already stated our belief, that the bulk of the French people were so ignorant, and had been so long habituated to political slavery, that they could form no idea of political liberty; and consequently to promise it to them, was to promise them that which could neither excite their hopes nor enter into their conceptions. But, as soon as they understood that their country was about to be attacked, that powerful and almost instinctive love of national independence, which operates in the breasts of the inhabitants of all countries, broke forth in an enthusiastic determination, not to allow foreigners to invade and overrun their country. In the case of France, too, this love of national independence was greatly aided by their love of national glory. They could not brook the idea, that France, the Great Nation, destined for universal empire, should become the vassal state, or even the temporary and degraded conquer of any foreign power. Besides, as the mass of the people had tasted of some of the beneficial effects of the Revolution, in the abolition of feudal services, and of those oppressions which are much more acutely and generally felt, than the want of political independence and liberty, by the people at large, in all countries, they were roused to defend the cause and exist-
ly present to their apprehensions, as to banish their mutual jealousy; while their selfish views too plainly proved, that if they succeeded in putting down the Revolution, they would not fail to quarrel among themselves about the spoil. Such appear to us to have been the principal causes which produced the military successes of the French. On their side, great enthusiasm, great talents, great exertion and perseverance, the strong motives of personal ambition, and the love of national glory and independence, all operating to one single object. On the side of the allies, talents neglected, and prejudices hurtful to their cause persevered in; no common bond of union; mutual suspicion and jealousy; an inadequate sense of their own danger; and treachery and disaffection among their subjects.

III. With respect to the change of the French go-
povtment, from a democratic form at least to a military despotism, it will be found, on examination, not to have been great in reality, and that the change which actually took place was produced by the operation of very simple and natural causes.

In the first place, the real change was not great; for it would be difficult to point out any period of the Re-
volution, in which the people were not subjected to a most arbitrary government—a government which well fitted them even for a military despotism. We shall not examine whether the state of France, threatened by numerous foes from without, and convulsed with intestine divisions, did not require and justify the arbitrary and severe government which was exercised over it; the cause or justification of this government is not now the object of inquiry. The fact is indisputable, and it accounts, in our opinion, for the ease with which the French passed from the forms of a democratic go-
povtment, to a military despotism. Besides, we should always recollect, that the French people had no con-
ception of political liberty; and if some idea and love of it sprang up, at the commencement of the Revolution, it was smothered by the tyranny and oppression which soon succeeded.

In the second place, the real change which took place from the form of democracy to military despotism, may be traced to obvious and satisfactory causes. The national love of glory disposes all Frenchmen to a military life; and throws round the military character a splen-
dour which conceals its tyrannical and oppressive nature. This splendour round the character of Bonaparte was, to the eyes of Frenchmen, of the most brilli-
ant and dazzling kind: he had gone further towards the realization of their fond hope, that France would attain universal empire, than any of their monarchs, and therefore they not only submitted, but were fa-
\r\n
vourably disposed, to the military government of a man who had done so much, and who, when their actual sovereign, they hoped would perfect the great undertak-
\r\n
aking which they had so near their hearts. A people whose fondest wishes were centered in national glory and universal empire, could not but be attached to a military government, as the best suited to the accom-
\r\n
plishment of those wishes, and to a man who they knew would conduct that military government with the great-
\r\n
est skill and success. Even those who were not in-
\r\n
fused with this national and characteristic passion, hailed Bonaparte as the man who had put an end to the convulsions that had so long agitated France; and though they still apprehended that his character, and the character of the people at large, would keep France in almost continual war, yet they at the same time
trusted that, under him, the internal state of the kingdom would be quiet, and they would at length be freed from a rapid succession of tyrants.

But there was another circumstance that reconciled the French people to a military government,—from the extension and long duration of the military system, a large portion of the population were interested in it. Their relations and friends were in the army; and if France were to become pacific, or if her government were not military, they would be thrown useless and unsupported on the world. Thus the same causes, which in part contributed to produce the military successes of the French, operated to render them fit subjects for a military government; and the revolution, by increasing and calling into more energetic and general action their love of glory, as well as by destroying all the habits of settled and regular life, also fitted them for a government which would cherish and flatter that love, and indulge their restless and irregular habits.

We shall defer at present the consideration of the effects on the character and condition of the French produced by the Revolution, as some of these effects were greatly heightened by the operation of the system which Bonaparte established and acted upon after he became Emperor; and therefore the subject will afterwards fall more properly under our notice. We shall now resume the history.

Moreau had long been the object of Bonaparte's hatred and jealousy; but no opportunity occurred of crushing or removing him, till the spring of 1804; when, in consequence of an accusation that he was implicated in a design to restore the Bourbons, he was seized and sentenced to be imprisoned; but his popularity with the army was so great, that Bonaparte commuted this sentence to banishment for life to the United States of America.

Symptoms of approaching hostilities with Germany had been long apparent in France; but Bonaparte did not leave Paris to put himself at the head of his armies till the 24th of September 1803. As soon as he reached this place, he issued a manifesto denouncing what he called the third coalition, which he attributed to the gold and hatred of England. As the operations and result of this war are detailed in the History of Austria, we shall run rapidly over them here. The French army consisted of five divisions: they crossed the Rhine the day after Bonaparte reached Strasburg. Hostilities commenced on the 7th, when the Austrians were defeated in attempting to oppose the passage of part of the French across the bridge of Donaunwirt. The main Austrian army was under General Mack; but his conduct, either from incapacity, or from the interference of the council of war at Vienna, was such, that the French advanced rapidly with upwards of 200,000 men, while he had not above 80,000. Swabia, Franconia, and Bavaria, were overruled in a very short time. Mack was entrenched at Ulm, where, on the 15th day of October, the 3rd day after firing the first shot, his army was so dreadfully beaten, that he was obliged to capitulate on the 17th. The Archduke Charles, at the head of 92,000 men, in vain endeavoured to prevent this dreadful disaster, by a rapid march from Italy; but coming up too late, and not being sufficiently strong to oppose Bonaparte, the latter pushed on towards Vienna, which he entered on the 12th of November. Austria, having been joined by Russia, resolved to hazard the fate of another battle, which was fought at Austerlitz on the 27th of November. The engagement commenced at sunrise; in less than an hour, the left wing of the allies was entirely cut off; and this was the forerunner of their total defeat. On the 5th of December an armistice took place, which was followed by the treaty of Presburg, on the 26th of that month. By this treaty, France was confirmed in the possession of all her conquests beyond the Alps, which had formerly belonged to Austria. Bonaparte was recognised as King of Italy; and to this kingdom the Emperor of Germany ceded his part of the states of Venice. The Electors of Bavaria and Wurtemburg, having been made kings by Bonaparte, were recognised as such by the Emperor; and the Tyrol and Swabian principalities of Austria assigned to them.

Bonaparte, on his return to Paris, stopped at Munich, where his son-in-law, Eugene Beauharnais, was married to the King of Bavaria's daughter. Having arrived at his capital on the 2nd of March 1806, he opened the sitting of the legislative body by a speech, in which he inveighed against England, as having fomented the late war, the third coalition, which however he had succeeded in destroying, and thus adding to the glory of France. The whole peninsula of Italy had been added to the French empire; Russia had been obliged to retreat to her own territories; Austria had been saved by his clemency; Spain continued faithful; with England he desired peace on the basis of the treaty of Amiens.

In the annual exposé, the extent and power of the French empire at this period were described. Besides the 110 departments of France itself, there were under the protection of the Imperial Eagle, Holland, Italy, Venice, Istria, Dalmatia, and Naples. The allies of France were, Bavaria, Wurtemburg, and Baden, besides several other of the principal powers in Germany. Each succeeding coalition which England had formed, had only increased the power and the territory of the French. By the first, they had gained Belgium, and the boundary of the Rhine; the union of Holland with France, and the conquest of those states which now formed the kingdom of Italy. The second had put them in possession of Piedmont. The third had added Savoy and Venice. The fourth, composed, with expressing Bonaparte's desire for peace, as he had exhausted military glory, and wished now for repose, in order that he might devote himself to the improvement of France, and the happiness of his people. On the 31st of March, several acts were presented to the senate, among which were those for annexing the city and territories of Venice to the kingdom of Italy; for placing Joseph Bonaparte on the throne of Naples; for conferring the principality of Neuchatel on Berthier; and titles of high distinction, principally taken from places in Italy, on his most distinguished generals. At the same time, Eugene Beauharnais, the son of Josephine, was appointed Viceroy of Italy.

Still the ambitious projects of Bonaparte were not satisfied; and he directed, or ordered, the government of Holland to petition for the honour of being placed under one of his family. Louis Bonaparte was accordingly proclaimed King of Holland.

Early in the year 1806, Mr Fox became Prime Minister of Britain, in consequence of the death of Mr Pitt, and he immediately began to put into execution such measures as he thought were likely to bring about a peace with France, the object that had always been near his heart. The particulars of this negotiation are given in the History of Britain, and therefore need not be repeated here. It is sufficient to observe, that it did not produce peace; that Russia refused to ratify the treaty which her minister had made with France; and
that before the Earl of Landerdale, the British Ambassador sent to Paris for the purpose of negotiating, had left that capital, Bonaparte had departed to put himself at the head of his armies against Prussia.

For some time past, the King of Prussia had given himself up to the interests and influence of Bonaparte, and had even shared in his unjust spoils, by annexing Hanover to his dominions: but in the negotiations with England, it was understood that England had required the cession of Hanover from France, and that France had agreed to yield it. This irritated the King of Prussia, who was thus convinced that Bonaparte regarded him merely as a vassal Prince, and perhaps as one whom he would destroy when he had accomplished more grand and serious undertakings. Prussia was also alarmed at the Conquest of the Rhine, which Bonaparte had formed; and which, being under his control, was either meant or at least calculated to curtail his power, and keep him in awe. The King of Prussia, moved by these considerations and apprehensions, prepared for war; and Bonaparte did not seem sure that hostilities were to commence, nor anxious to pacify the King. On the 24th of September, Bonaparte left Paris, to put himself at the head of his armies. The discussions, however, were still continued till the 5th of October, when both monarchs were at the head quarters of their respective troops; a few days afterwards, a declaration of war was published by Prussia. The King was so confident in his own strength, that just before the commencement of hostilities, he refrained from any attempts at reinforcement from other powers.

The French army advanced in three divisions; the right, under Ney and Soult, with some Bavarian troops, advanced on Hett; the centre consisted of the reserve, under the Grand Duke of Berg; the corps of Bernadotte and Davoust, and the imperial guards, marched to Gera; the left, under Lannes and Augereau, took the route to Cobourg. The Prussian army had taken a strong position along the north of Franckfort on the Maine; but this they were compelled to leave, in consequence of the French unexpectedly turning their left wing, and took up a position near Jena. Here they were attacked by the French on the morning of the 14th of October, and in less than an hour the action became general. The force on each side was nearly equal, comprising about 250,000 men, and 700 pieces of cannon. At one period of the battle, the issue was doubtful; but it was turned in favour of the French, principally by a charge of their dragoons and cuirassiers. The Prussian infantry, unable to resist them, were broken and thrown into confusion, the day was lost, and the Prussian army nearly annihilated, 40,000 being killed, wounded, and taken, including about 20 generals; among whom, the Duke of Brunswick was murdered. In consequence of this victory, Erfurt, Magdeburg, and Stettin, all places of great strength and importance, were reduced; and on the 27th of October, Bonaparte arrived at Berlin. The only part of the Prussian army which did not immediately yield, or was not utterly dispersed, was the division under Blucher, who displayed wonderful activity and courage in his retreat to Lubec, where, however, he was obliged to capitulate.

The King of Prussia, thus deprived of his whole army, retreated first to Custrin, and afterwards to Koningsberg, where he awaited the arrival of the Russians, without whose assistance he had imprudently engaged in the contest.

Those Princes of Germany who had joined the King of Prussia in this short and unfortunate war, were severely punished by the conqueror. The Elector of Hesse, and the young Duke of Brunswick, were deprived of their dominions; Mecklenburg was taken possession of; the Elector of Saxony, however, was pardoned, as he had been compelled to act against France. Hanover was occupied; and Fulda, Cassel, and Hamburg, were taken possession of in the name of Bonaparte.

In the mean time, the Russian army destined for the support of Prussia, had crossed the Vistula under general Benningsen. The French also advanced into Poland, and, by their manoeuvres and superior force, obliged the Russians to recross the Vistula. Their retreat, however, having enabled them to join strong reinforcements, they again advanced, and fixed their head-quarters at Pultusk. Here, on the 26th of December, a dreadful battle was fought, which continued for some time with considerable vicissitude; but at length terminated in the defeat of the Russians, who fell considerably back. Bonaparte, however, found his army so much weakened by his dearly bought victory, that this circumstance, and the severity of the winter in this country, induced him to go into winter quarters. The King of Prussia, still more dispirited by the misfortunes of his ally, endeavoured to procure peace, but in vain.

It has already been mentioned, that Bonaparte had made his brother Joseph king of Naples. It may, however, be proper briefly to narrate the events, which deprived the legitimate monarch of his throne. He had lately made peace with Bonaparte, but by permitting an Anglo-Russian army to embark at Naples, which was to act against France, he incurred the displeasure of Bonaparte. Joseph Bonaparte was sent with an army against him; the Neapolitan troops could make no resistance; the kingdom was in a very short time over-run and subdued; and Joseph Bonaparte entered his capital in triumph.

Although Bonaparte, after the battle of Pultusk, deemed it necessary to go into winter quarters with his main army, yet the rest of his forces were by no means idle. Silesia was invaded; and on the 5th of January 1807, Breslau surrendered. The other fortresses in this country did not hold out long afterwards. Other divisions of his army were employed in besieging Stralsund, Colberg, and Dantzic. But the efforts of Bonaparte were principally directed against the Russian army, which early in 1807 was in great force. About the end of January he quitted Warsaw, (where he had done nothing towards the re-establishment of Poland, though by promising this he had gained over the Poles to his interest,) and joined his army. Operations immediately commenced, the result of which was, that the Russians were obliged to retreat, and take up a position behind Eylau. Here Bonaparte attacked them; the contest was desperate. At one period of it, a thick fall of snow intercepted the view of the French divisions, and for a considerable time they were exposed to extreme uncertainty and danger. At length Marshal Davoust succeeded in outflanking the Russians, who retreated, but not in the least disorder. (See England.) Both parties claimed the victory; in fact, the battle was indecisive, except so far that the French compelled the Russians to retreat on the day when it took place; for they in their turn, instead of passing the Pregel in pursuit of the enemy, or pushing on to Koningsberg, retired to their entrenchments. Soon afterwards, the Emperor Alexander, and his brother Constantine, joined the Russian army with
upwards of 60,000 troops; and Bonaparte ordered strong reinforcements from France and Germany.

A. D. 1807.

In the mean time, the siege of Danzig was prosecuted with great vigour, and it was obstinately defended. The garrison consisted of 16,000 men. On the 24th of April the bombardment began; and in one night three attempts were made by the French to gain the citadel, but they were ineffectual. As the relief of this place was an object of great importance to the allies, they resolved to attempt it: the Russians first advanced for that purpose, but they failed, and suffered a very severe loss. The Prussians next endeavoured to penetrate to Danzig, but they were soon obliged to abandon their enterprise. On the 21st of May, every thing being prepared for the assault, the governor, (his garrison being reduced to 9000 men and there being no hope of relief,) agreed to surrender. This conquest was of great importance to Bonaparte, as Danzig strengthened the left wing of his army, while the centre was supported by Thorn, and the right by Praga.

As Bonaparte found that the forces of Russia were more formidable than he expected, he endeavoured to reduce the number of his enemies, by detaching Sweden from the allies; but not succeeding, the war against that power was carried on in Pomerania with such vigour and effect, that the Swedish general agreed to an armistice, which, however, was to be submitted to his Swedish Majesty. He did not approve of it, and resolved to take the command of the army himself. As soon as he landed in Pomerania, he directed his thoughts to the fortifications of Stralsund, which the French were at that time besieging. His army consisted of about 30,000 Swedes, and 4000 Prussians. But we must suspend our account of his operations, till we bring the narration of the contest between the French and Russians to a close.

Bonaparte, after the battle of Eylau, and the fall of Danzig, resolved to strengthen his positions, that he might be able to resist the attack of the Russians, who now seemed disposed to become the assailants. On the 5th of June, the Russians did attack him in force, and gained some advantages. On the 6th, Bonaparte arrived and took the command. He immediately ordered an attempt to be made to recover the positions they had lost; the French were successful, and not only regained their positions, but forced the Russians to fall back. From the 5th to the 12th of the month, there had been constant engagements, in which the loss was very considerable on each side. On the 13th, Bonaparte had pushed the Russians back to Friedland. Here, on the 14th, the anniversary of the battle of Marengo, he determined to attack them. The battle lasted from five in the morning till seven at night. At the close of the day, nearly all the French force fell on the centre of the Russians: it gave way, and they lost the battle. Their loss was very great, and they were pursued as far as the Niemen, where they were joined by large reinforcements from Russia. In consequence of this, the Russian general resolved to hazard another battle, and crossing the Niemen, stationed his army on a great plain to the right of the town of Tilsit. The fall of Königsberg was the immediate consequence of the battle of Friedland; the garrison evacuating it, and joining the Russian army.

While Bonaparte was advancing towards Tilsit, an overture was made by the Russian general Bennigsen to the Duke of Berg, for an armistice. On the 22d of June, it was signed; and, on the 24th, an interview took place between Bonaparte and the Emperor of Rus-
Augsburg Conference, and the accession of Joseph Bonaparte, were therefore resolved upon. The means which he employed to persuade the King to resign his throne in favour of his son Ferdinand, and to entice Ferdinand into France, and to surrender his claims to him,—the insurrection of the Spaniards,—their answered calls to Britain for assistance,—the battles that were fought between them and the French,—the retreat of Sir John Moore,—and the masterly operations, and brilliant victories of Lord Wellington till the reduction of Ciudad Rodrigo on the 19th of January 1812, are fully detailed in the History of Britain. We shall therefore omit these parts of the history of France which relate to the operations of her army in the Peninsula, till we come to the events of that year; and confine ourselves, in the intermediate period, to the operations of Bonaparte in the other parts of Europe, and the internal transactions of France.

The same system of concealment and misrepresentation which Bonaparte had practised respecting all his reverses, he extended to the affairs of Spain. In 1808, when Joseph Bonaparte was obliged to leave Madrid, not a word was said of Spain in the Moniteur. But his reverses, and the enthusiasm as well as the extent of the opposition to him in the Peninsula, were well known in all parts of Europe; and, as might be expected, received with satisfaction and joy. Austria, who had reluctantly submitted to the last peace, had been for some time employed in bringing her finances into order, and in forming magazines on her frontier. These circumstances did not fail to excite the suspicion of Bonaparte; and a long correspondence took place on the subject between the Austrian ambassador at Paris, and the French minister for foreign affairs; but the Austrians persevered in their military preparations, notwithstanding the remonstrances, and even the threatening language of the latter. Orders were therefore transmitted from Paris, to the members of the Confederation of the Rhine, to call out their respective quotas of troops, 60,000 of whom were taken into the pay of France, and sent into that country to replace those French troops whom it was found necessary to send into Spain.

Under the circumstances in which he was placed, it was of great importance for Bonaparte to secure the neutrality of the Emperor of Russia; a conference, therefore, took place between them on the 27th of September, at Erfurt, in the former electorate of Mayence. The Emperor seems to have entered into the views of Bonaparte, and the latter in return agreed to evacuate the Prussian territories, as soon as the contributions, which he reduced to one third, were paid up. By this concession to the wishes of the Emperor of Russia, Bonaparte set at liberty a great number of his troops, who were instantly marched for the Peninsula. The two sovereigns also agreed to propose peace to Britain, but, as we have already noticed in the history of that country, the proposal was rejected.

This year did not pass over, without new and additional proofs of the rapacity and unsatisfactory nature of Bonaparte's ambition. The military posts of Kelh, Wesel, Cassel on the Rhine, and Flushing, were annexed to France on the east and north; while on the side of Italy, Rome, Parma, Placentia, and Ancona, suffered a similar fate.

Though Austria had been long preparing for the renewal of hostilities with France, yet she did not issue a formal declaration of war till the 6th of April 1809. At this period she had an army consisting of nine corps, each corps consisting of 30,000 men; the first six were under the immediate orders of the Archduke Charles; the seventh was under the Archduke John in Poland. Besides these, there were two corps of reserve, one of 20,000 men commanded by Prince John of Lichtenstein; the other of 10,000, under General Kinnayer; and about 25,000 partizans in the Tyrol, Carinthia, and on the confines of Bohemia. The French were not inferior in respect to numbers, and they occupied the following positions: a corps entirely of French at Ratisbon, under Marshal Davoust; another under Massena at Ulm; and a third under Oudinot at Augsburg; three divisions of Bavarians were posted at Munich, Landshut, and Strauburg: the Saxons were encamped under the walls of Dresden; and the Poles near Warsaw.

As soon as Bonaparte learnt that the Austrians had crossed the Inn, he left Paris on the 13th of April; on the 17th he arrived at Bonn, and from there fixed his head quarters. On the 19th, the different corps of the French began to unite. At Ingolstadt the plan of Bonaparte was unfolded; which was to manoeuvre the Austrians, whose line was extended from Neustadt to Landshut; to break the line, and come between the Archduke Charles and the corps commanded by his brother. In consequence of the successes of the French, particularly at Eckmuhl, the Archduke was forced to cross the Danube at Ratisbon, in order to form a junction with General Bellegarde, who had been employed in keeping the French in check, on the frontier of Bohemia. The Archduke finding he could not defend Ratisbon, was obliged to continue his retreat; and Bonaparte, following the course of the Danube, advanced rapidly towards Vienna; on the 10th of May, he appeared before this city, which, after some show of resistance, he entered. In the mean time, the Archduke Charles, having learnt the fate of Vienna, moved down on the left bank of the Danube, for the purpose of watching the motions of the French; and fixed his head quarters, on the 16th of May, at Ebersdorf. Bonaparte immediately formed the design of attacking him here, and for this purpose marched along the south bank of the river, till he reached the distance of about six miles from Vienna, at which place its breadth and rapidity are broken by two islands. At this point he resolved to cross it. As the French advanced the Archduke retreated, and the right wing of the former was posted near the village of Essling, while the left was supported by the village of Aspern. Here on the 21st and 22d two dreadful and sanguinary battles were fought: the battle of the 21st was terminated only by the darkness of the night, at which time the French were driven from Aspern, but still retained Essling. On the morning of the 22d they regained Aspern; but by repeated attacks, the Austrians succeeded in driving them both from it and Essling. In the night between the 22d and 23d, they retreated from the left bank of the Danube, and took up a position on one of the islands.

In the mean time, the war was proceeding in Italy, where the Archduke John, and the Viceroy Eugene of Italy, Beaunarsois, were opposed to each other. At first the Archduke was successful; Padua and Vicenza were taken, the Adige crossed, and Venice threatened; but the Viceroy having been reinforced, retook Padua and
Vicenza, crossed the Brenta, and drove the Austrians before him. At this period, these hostile armies were sent for, in order to reinforce the grand armies on the Danube; but as they were proceeding towards Austria from Italy, they met at Raab, where a severe engagement took place on the 14th of June, the anniversary of the battle of Marengo. The battle began at two o'clock in the afternoon, and though the French were superior in numbers, victory was long doubtful; at length, the troops of the Hungarian insurrection, unacquainted with service, gave way, and the Austrians were forced to save themselves by flight. The Archduke Charles retreated to Conna, in order to secure his junction with the grand Austrian army; while the Viceroy about the same time accomplished the same object.

On the 4th of July, the whole army of Bonaparte was concentrated in or near the island in the Danube, where the Archduke Charles had not deemed it prudent to attack them. Bonaparte, having been reinforced by the Viceroy, resolved to cross the river, and try the issue of another engagement with the Archduke; for this purpose, in a very short space of time, three bridges were thrown across it, by which he intended to pass, and another bridge opposite to Essling, erected in order to draw off the attention of the Archduke to this quarter. In the short space of two hours, during the night of the 4th, while the Austrians were expecting to be attacked on their right, near Essling, the French passed the Danube, and on the morning of the 5th appeared drawn up on the left of the Austrians.

This masterly manoeuvre, by which the Archduke had been completely deceived, gave Bonaparte a great advantage; which he did not fail to profit by, in the obstinate but decisive battle of Wagram, which was fought on the evening of the 5th and during the 6th of July. During the first movements on the former day, the Archduke was obliged to give up his entrenchments; and on the 6th, Bonaparte, having strengthened his centre, attacked the weakened centre of the Austrians; the consequence was, that the latter gave way, and the wings, being thus exposed, also retreated. After this battle, all thoughts of serious resistance to Bonaparte were given up. Proposals for an armistice were carried to him from the Emperor Francis, which was agreed to, and signed immediately. By one article it was stipulated, that the Austrians were not to afford any succour to the Tyrolese.

These brave and bold mountaineers, as soon as they learned the rupture between France and Austria, resolved to use their utmost efforts to shake off the yoke of Bavaria. At first they were successful; the Bavarian troops, though 27,000 strong, having been defeated by them. A still greater force was then sent against them under Marshal Lefebre, consisting of French, Bavarian, and Saxon troops. These they could not venture to meet in the field, but, taking advantage of the nature of their country, they destroyed thousands of them as they passed through the gorges of the mountains, by precipitating masses of rock on them. When, however, the armistice was concluded between France and Austria, their cause became hopeless, though they continued, for some time afterwards, to fight obstinately for their national independence.

On the 14th of October, a treaty of peace was signed at Vienna between France and Austria. By this treaty, the latter ceded to the former all her sea coast; and the kingdoms of Saxony and Bavaria were enlarged, so as to become sufficient checks on her. Prussia was compensated for her neutrality by the cession of part of Galicia; and the Emperor Francis agreed to acknowledge Joseph Bonaparte King of Spain. Such were the leading articles of this treaty, that were communicated to the world at the time; but the Emperor Francis obtained these favourable terms only by a sacrifice of a domestic nature, which we shall afterwards have occasion to notice.

Soon after Bonaparte’s return to France, the meetings of the legislature were opened by a speech from him. In this speech, the events of the year 1809, and the legislature of the state of France at the close of it, were, as usual, the principal topics. He was marching, he said, on Cadiz and Lisbon, when he was under the necessity of treading back his steps, and planting his eagles on the ramparts of Vienna. Three months had seen the rise and termination of this fourth Punic war. He next adverted to the Walcheren expedition; and, in short and unsatisfactory terms, to the state of Spain. The annexation of Tuscany and the Ionian states were next dwelt upon; but that part of the treaty of Vienna which had put him in possession of the Illyrian provinces, and thus brought the French empire contiguous to the empire of Constantinople, seemed the favourite topics of this speech. “I shall find myself in a situation,” he observes, “to watch over the first interests of my commerce in the Mediterranean, the Adriatic, and the Levant. I will protect the Porte, if the Porte withdraws itself from the fatal influence of England. I shall know how to punish her, if she suffers herself to be governed by cunning and pernicious counsels.” In the course of 1809, Bonaparte had advanced one step towards blotting out even the nominal independence of Switzerland, by declaring himself the Mediator of that country. This he adverted to in his speech; and at the same time he hinted, that changes might become necessary in Holland, as she was equally injured by France and England, and yet was the debouch of the principal arteries of his empire.

Bonaparte having thus succeeded in all his plans of aggrandizement except what regarded Spain, and being doubtless convinced that that country also would soon be reduced; having fixed all his brothers (except Lucien) on thrones, began to reflect on the probable fate of his own vast empire, on the event of his death. There was no probability of his having issue by Josephine; besides, even if there were, his power would be much more firmly consolidated, if he were united with some of the ancient sovereign families of Europe. Considerations of political ambition always weighed most in his mind; but by such a marriage, not only would his empire be strengthened, and, if there were no other, rendered secure after his death, but his personal vanity would be gratified. The divorce of the Empress Josephine, to whom he appears to have been much attached, was therefore agreed upon; and she, though equally attached to him, seems to have consented to this measure without reluctance. It took place in December 1809; but it was not till the 27th of February 1810, that it was publicly and certainly known whom he intended to marry. On that day, he announced, by a message to the Senate, that Berthier had been sent by him to Vienna, to demand for him the hand of the Archduchess Maria Louisa, daughter of the Emperor Francis. The ceremony of marriage was performed on the 11th of March at Vienna, the Archduke Charles representing Bonaparte on this occasion.

Early in 1810, Bonaparte began to unfold his designs upon Holland. A French army of 40,000 men
occupied it; but at first he seemed disposed to be content with the annexation of only part of it,—the left bank of the Waal. As this, however, did not serve his purpose of totally excluding British goods, about the middle of June 20,000 French troops assembled in the neighbourhood of Utrecht, and on the 29th of that month the King of Holland received official information, that his majesty the Emperor insisted on the occupation of Amsterdam, and the establishment of French head quarters in that capital. Louis therefore resigned his throne, but at first only in favour of his son. Soon afterwards, however, Holland was annexed to France. As a justification of this measure, Bonaparte, in his message to the Conservative Senate, stated, that, in consequence of the English orders in council having destroyed the public law of Europe, new securities had become necessary, which could only be obtained by the annexation of the mouths of the Scheldt, the Meuse, the Rhine, the Ems, the Weser, and the Elbe, to France, and the establishment of an internal navigation between France and the Baltic. About the same time, the Hans Towns and the Valais were annexed to France; and the Count of Semonville, who brought up the report of the Senator Consultum respecting these annexations, expressly pointed out the gratification and accomplishment of the views of Bonaparte, which were thus attained. "At length, after a struggle glorious for France, for ten years, the most extraordinary genius that ever nature in her munificence produced, had reunited, and held in his triumph, over the scattered wrecks of the empire of Charlemagne."

According to the plan of the annexation of Holland, Amsterdam was to rank as the third city in the French empire, Rome being the second. The whole population of Bonaparte's dominion, before the annexation of Rome, Holland, the Valais, and the Hans Towns, amounted to 38,080,443 persons, not including the military actually bearing arms. After these annexations, it was computed at 43,000,000. Hanover was annexed to the kingdom of Westphalia.

To recruit the French armies, the conscription was again anticipated, 120,000 of the conscripts of 1811 being placed at the disposal of the minister of war for the service of 1810. During these measures, which plainly intimated that Bonaparte was resolved not to be content with the empire of Charlemagne, the most vexatious and despotic decrees were passed at Paris. By one of them, all servants of both sexes were obliged to register their names in a book kept by the Prefect of the Police. By another decree, the liberty of the press was utterly destroyed; the number of printers in Paris being reduced to sixty, and those in the departments in the same proportion; and the number of printing presses in the capital was to be only four, in each department only two. Another decree, respecting prisoners, expressly declared, that there were many persons charged with crimes against the state, whom it was not safe either to liberate or bring to trial. But his most severe and frequent decrees were issued against the introduction of British merchandise into the continent. Not only were military governors appointed at the ports of Germany annexed to France, but at Danzig, Colberg, &c. for preventing its introduction. General Flapp, who commanded the army employed on this singular service, had his head quarters at the former place. All English merchandise, whether taken by land or sea, was ordered to be burnt.

As, however, the prohibition of colonial produce created great dissatisfaction in his dominions, a decree was passed on the 25th of March, 1811, enjoining the culture of the beet root and the plant wool, to supply the place of the sugar cane and indigo; and so confident was Bonaparte of success in this scheme, that the prohibition of the sugar and indigo of the Indies, as English commodities, was announced for the 1st of January 1813.

On the 20th of April, the Empress was delivered of a son, for whom was revived the title of King of Rome. On the 17th of June, the French national ecclesiastical council was opened at Paris; the proceedings and result of which were kept a profound secret; but it is generally supposed that they were not agreeable to the wishes of Bonaparte. On the 29th of June the minister of the interior presented the usual annual exposé of the state of France. On these state papers no implicit confidence can be placed, as they evidently contain much of what is false, and much that isaggerated; yet, by a careful comparison of them with one another, with what the other official papers furnish us with, and with what we know must have taken place, we may be able to glean some interesting and important facts from them. The exposé of this year states, that, "since the last session, the empire had received an addition of 16 departments, five millions of people, a territory yielding a revenue of 100 millions of livres, 900 leagues of coast, with all their maritime means. The mouths of the Rhine, the Meuse, and the Scheldt, were not then French; the circulation of the interior of the empire was circumscribed; the productions of its central departments could not reach the sea without being subjected to the inspection of foreign custom-houses. These inconveniences have for ever disappeared. The maritime arsenal of the Scheldt, whence so many hopes are founded, has thereby received all the development which it needed. The mouths of the Ems, the Weser, and the Elbe, placed in our hands all the timber that Germany furnishes. The frontiers of the empire lean on the Baltic; and thus, having a direct communication with the north, it will be easy for us to draw thence, masts, hemp, iron, and such other naval stores as we may want. We at this moment unite all that France, Germany, and Italy produce as materials for the construction of ships."

This statement of the exposé deserves particular attention, as it at once points out the extent and resources of the empire of Bonaparte, at the period when it was at its greatest height; and demonstrates the extreme folly and madness of that ambition, which, not satisfied with such an empire, brought it to ruin by aiming at enlarging it.

The restlessness of this ambition, which, when there was no opportunity for making real acquisitions to the French empire, employed itself in the most minute annexation of territories, which in fact had been in the same proportion; and the number of printing presses in the capital was to be only four, in each department only two. Another decree, respecting prisoners, expressly declared, that there were many persons charged with crimes against the state, whom it was not safe either to liberate or bring to trial. But his most severe and frequent decrees were issued against the introduction of British merchandise into the continent. Not only were military governors appointed at the ports of Germany annexed to France, but at Danzig, Colberg, &c. for preventing its introduction. General Flapp, who commanded the army employed on this singular service, had his head quarters at the former place. All English merchandise, whether taken by land or sea, was ordered to be burnt.

As, however, the prohibition of colonial produce created great dissatisfaction in his dominions, a decree was passed on the 25th of March, 1811, enjoining the culture of the beet root and the plant wool, to supply the place of the sugar cane and indigo; and so confident was Bonaparte of success in this scheme, that the prohibition of the sugar and indigo of the Indies, as English commodities, was announced for the 1st of January 1813.

On the 20th of April, the Empress was delivered of a son, for whom was revived the title of King of Rome. On the 17th of June, the French national ecclesiastical council was opened at Paris; the proceedings and result of which were kept a profound secret; but it is generally supposed that they were not agreeable to the wishes of Bonaparte. On the 29th of June the minister of the interior presented the usual annual exposé of the state of France. On these state papers no implicit confidence can be placed, as they evidently contain much of what is false, and much that is exaggerated; yet, by a careful comparison of them with one another, with what the other official papers furnish us with, and with what we know must have taken place, we may be able to glean some interesting and important facts from them. The exposé of this year states, that, "since the last session, the empire had received an addition of 16 departments, five millions of people, a territory yielding a revenue of 100 millions of livres, 900 leagues of coast, with all their maritime means. The mouths of the Rhine, the Meuse, and the Scheldt, were not then French; the circulation of the interior of the empire was circumscribed; the productions of its central departments could not reach the sea without being subjected to the inspection of foreign custom-houses. These inconveniences have for ever disappeared. The maritime arsenal of the Scheldt, whence so many hopes are founded, has thereby received all the development which it needed. The mouths of the Ems, the Weser, and the Elbe, placed in our hands all the timber that Germany furnishes. The frontiers of the empire lean on the Baltic; and thus, having a direct communication with the north, it will be easy for us to draw thence, masts, hemp, iron, and such other naval stores as we may want. We at this moment unite all that France, Germany, and Italy produce as materials for the construction of ships."

This statement of the exposé deserves particular attention, as it at once points out the extent and resources of the empire of Bonaparte, at the period when it was at its greatest height; and demonstrates the extreme folly and madness of that ambition, which, not satisfied with such an empire, brought it to ruin by aiming at enlarging it.

The restlessness of this ambition, which, when there was no opportunity for making real acquisitions to the French empire, employed itself in the most minute annexation of territories, which in fact had been before annexed,

Further en
all the works that were going on in the dock yards, and the ships that were building. From Antwerp he went to Amsterdam, whence, on the 18th of October, he issued a decree for assembling in council the deputies to the legislative body, from the Dutch departments. In consequence of this meeting, a number of decrees were issued, the most important of which were to the following purpose: The departments and their boundaries—the introduction of the French system of taxation into Holland, on 1st of January 1812—the establishment of two imperial manufactories of tobacco—roads with their tolls—canals. Conscripts for conscription was to go from Amsterdam to the Hague—the proportion of the budget in Holland for the year 1810, by which the revenue is fixed at 95 millions of livres, and the expenses at 111 millions—the establishment of two academies and secondary schools, on the French plan, &c. Bonaparte returned to Paris on the 11th of November; and soon afterwards issued an order for the immediate call of 120,000 conscripts of the year 1812.

This increase of his forces was occasioned by the disputes which, during 1811, had arisen between the Emperor of Russia and Bonaparte: the former, by the treaty of Tilsit, had agreed to exclude British goods from his dominions; but the consequences of this measure were so extremely prejudicial to the finances of his empire, already nearly exhausted, and to the interest of his nobles, many of whom depended entirely on the interchange of the produce of their estates for the merchandise of England, that Alexander was induced to connive at the infraction of the treaty in respect. This gave umbrage to Bonaparte; and as Alexander, moreover, would not yield up Finland to Sweden, which Bonaparte required him to do, the difference was increased and exasperated. The whole year 1811 passed in negotiations and discussions between France and Russia; but as neither party was prepared for war, hostilities were deferred. Bonaparte still saw the Peninsula not only unsubdued, but requiring almost constantly fresh troops; and the Emperor Alexander, fatally convinced of the ruin attending the commencement of hostilities, before every thing was planned and prepared, resolved not to commit himself hastily.

But though Bonaparte was afraid to act in a decidedly hostile manner towards the Emperor of Russia, the King of Prussia received no such scrupulous treatment from him. Indeed he seemed resolved to humble that monarch as much as possible; and obliged him, much against his will, to join the confederacy of the Rhine, and to place a considerable body of his troops under the orders of General Rapp, the French commander on the southern coast of the Baltic. This confederate was now extremely powerful: At the beginning of this year, the states composing it contained a territory of 5703 square leagues, with a population of nearly 15 millions; and the contingent of troops, which its 39 members furnished, was fixed at 118,082 men: these were taken, in the autumn of 1811, into the pay of France. See Confederation of the Rhine.

As the history of the war in Spain, which is given under the article Britain, terminates with the reduction of Ciudad Rodrigo, in January 1812, we shall resume and continue it in this place.

The preservation of Ciudad Rodrigo being of the utmost consequence to the French, Marshal Marmont marched to its relief; before he arrived, however, it surrendered. Lord Wellington's next enterprise was Badajoz, which had been for some time blockaded by General Hill. This place was commanded by Philip-pon, a distinguished officer in the French service, especially as an engineer, and he left no means untried by which he could strengthen the fortifications, or impede the progress of the besiegers. Nothing, however, could withstand the valour of the British, who carried the place by storm, after suffering a severe loss, on the 7th of April. Soult had pushed forward to relieve this place, but as soon as he learned its fate, he commenced his retreat: his rear was closely followed by the British cavalry, and suffered considerably. On the 11th of April he evacuated the province of Estremadura entirely. In the mean time, Marmont had set down before Ciudad Rodrigo, in the hopes of drawing off Lord Wellington from the siege of Badajoz; but not succeeding in his object, and learning that his Lordship was advancing into Castile, he broke up from Ciudad Rodrigo, and advanced as far as Castel Blance; but from this place he again retreated.

In May, the head quarters of Marmont were at Salamanca, of Drouet at Aguazu, and of Soult at Seville. Lord Wellington was posted at Fuente de Guínado. His Lordship, at this time, formed a plan to cut off the communication between the French army of Portugal, and that before Cadiz; and, for this purpose, by a series of masterly manœuvres, he made himself master of the bridge of Almaraz, on the eastern side of the province of Estremadura. Here again Marshal Marmont was too slow in his movements, for he did not arrive till the bridge was in the possession of the English. The next object of Lord Wellington was Salamanca, before which some French troops were posted, but these retired on his Lordship's approach. Marmont, however, though he was not able, or did not deem it prudent, to attempt preventing the loss of Salamanca, resolved to attempt its recapture. Accordingly, he collected his army on the Douro, betwixt the 10th and 15th of June, and moved forward on the 20th. Lord Wellington did not refuse battle; but Marmont again retreated, retaining, however, a communication with some forts in the neighbourhood of the city, which still held out. Against these forts Lord Wellington directed all his efforts, and having reduced them, he pushed forward against Marmont. The latter retired, crossed the Douro, and took up a strong position on the bank of that river. This position appeared to Lord Wellington so strong, that, in order to draw Marmont away from it, he moved in such a direction, as seemed to threaten Madrid. The French general also, about the same time, endeavoured to carry into execution a scheme for cutting off the communication between the British army and Ciudad Rodrigo; and, for this purpose, having been reinforced, he moved in such a manner, as to threaten the left of the British. Lord Wellington, on seeing this, retreated a little, so as to render it secure; and Marmont being thus foiled, attempted to turn the right. Lord Wellington now manoeuvred in such a manner, as would not only protect it, but enable him to take advantage of any blunder which Marmont might commit. Thus several days were spent. Marmont, constantly manoeuvring to turn the right of the British, and Lord Wellington, making correspondent movements, in order to defeat his object. At last, Marmont, in his anxiety not to out-maneuvre the British army, neglected the proper defence of his own, extending his line to the left, so far as to weaken the main body considerably. This fault Lord Wellington instantly perceived, and took advantage of it. The centre and left of the French were attacked with such successful and impetuous bravery, that they were soon beaten. The right would have as

Battle of Salamanca.
spedily shared the same fate, but it was reinforced by the troops that fled from the left, and held out till it was attacked in front, when it also gave way. It was now dark, but the French were pursued; and, during the battle and pursuit, suffered so severely, that only a few escaped to Valladolid. Marmont himself was wounded early in the battle.

Joseph Bonaparte had left Madrid with the army of the centre, in the hope of being able to join Marmont before his engagement with Lord Wellington; but, on learning the issue of the battle of Salamanca, he retreated in such a manner, as he trusted would draw off his Lordship from the pursuit of the defeated army. In this also he was disappointed, and Madrid was now abandoned to its fate. Nor was this the only result of the battle: Soult withdrew from the South of Spain; and the siege of Cadiz, which the French had continued so very long, was raised. The object of this general, as well as of Marmont, was now to compel Lord Wellington to abandon Madrid of which he had taken unmolested possession; and as they advanced with superior forces, and in such a direction as threatened to cut off his Lordship's communication with the other British forces in Spain, he evacuated the capital on the 1st of September, leaving a force under General Hill, which he hoped would be able to protect it; but Soult having joined Joseph Bonaparte, the English general found himself under the necessity of abandoning Madrid to its fate.

Lord Wellington, thus compelled to quit the capital, resolved, if possible, to bring Marmont to an engagement; but, previously, it was necessary to reduce Burgos. About the middle of September, operations were commenced against this place. The commander, fully sensible of its importance, and that, till it was reduced, Lord Wellington could not safely advance against Marmont, defended it with great skill and bravery. Little or no impression had been made on it, when his Lordship learnt that Souham, who had succeeded Marmont, was approaching with a large force, and that General Hill, after the loss of Madrid, was closely pressed by Soult. This intelligence induced his Lordship to abandon the siege; and, in his retreat, he was closely followed by Souham; and General Hill retreating in such a direction as to join his Lordship, and being followed by Soult, in a short time the two British and the two French armies were united. As, however, the latter were much more numerous than the former, they obliged Lord Wellington to continue his retreat to the confines of Portugal.

At the close of the campaign, the French armies, exclusively of those which were wholly occupied by the desultory warfare of the Spaniards, consisted of about 104,000 men; of these, 72,000 infantry, and 2000 cavalry were under the command of Soult, who directed the armies formerly under the command of Joseph Bonaparte, and Souham. Suchet, in the south of Spain, had with him 18,000 infantry, and 4,000 cavalry, to oppose the Spaniards there, and an Anglo-Sicilian force, which had lately landed. Opposed to the French armies, were about 70,000 British, Germans, and Portuguese. But of the French, a large proportion consisted of young conscripts. With respect to artillery, the French were superior. The numerical force of their cavalry was also greater, but they were individually inferior to the British.

We have already mentioned the causes of the dispute between the Emperor Alexander and Bonaparte. As the discussions that took place in 1811, did not promise an amicable adjustment, Bonaparte prepared for war, by retaining possession of the Russian fortresses in the north of Germany, and sending large bodies of troops there. Nor was the Emperor Alexander idle; he endeavoured, indeed, to prevent the recurrence of hostilities; but finding that impracticable, he used his utmost endeavours to render the resources of his vast empire available, in the event of a war with France, and he courted the friendship of Britain. The organization of the army was also improved. By these measures the Emperor Alexander saw himself, at the end of 1811, possessed of forces amounting to nearly 400,000 men, 300,000 of which he could bring against the French. When the dispute between France and Russia began, the forces which Bonaparte could spare, in the event of an immediate war, were comparatively few; he therefore protracted the negotiation, till he had assembled a more numerous, and, in every respect, a better equipped army, than he had ever before led into the field. The contingent of the confederation of the Rhine was augmented. The King of Saxony was called upon to join in the war, on the ground that Russia threatened the Polish possessions, which Bonaparte had given him. From the southern extremity of Europe, Murat marched his Italian troops. The King of Prussia reluctantly contributed nearly all his army; and Austria was called upon to fulfill her engagements, by which, in the event of a war, she was to support France. All the best troops that Bonaparte had in the Peninsula were marched to the north of Germany. In short, all Europe, from the Pyrenees to the Baltic on its western side, and from the extremity of Italy to the same sea on its eastern side, and from the Atlantic Ocean to the confines of Poland, was leagued, under Bonaparte, against Russia. For such an immense army, about to invade a country nearly barbarous and desolate, it was necessary to provide enormous stores of provision, ammunition, &c. These were all brought up to the north of Germany, and such arrangements for their conveyance made, as Bonaparte expected would furnish him with a regular and full supply, till the Emperor Alexander was intimidated into submission. For there can be no doubt, that he expected, by the formidable nature of his preparations, or, at most, by the decisive blow which he firmly, believed he should soon be able to strike, that Alexander would see for peace, on such conditions as he chose to give.

On the 9th of May, Bonaparte having collected an army of at least 400,000 men, set out from St Cloud, of 1812. On the 6th of June he crossed the Vistula. On the 22d of that month, he formally declared war against Russia; and two days afterwards, he crossed the Nemen, and entered the Russian territories.

Hitherto the Russians had made little or no resistance; but as they had marked out the first line of defence on the banks of the Dwina, it was supposed that there they would seriously oppose their invaders. The plan on which they had resolved to act was, however, different. Knowing the impetuous activity of Bonaparte, and that he had been accustomed to astonish and intimidate by the rapidity of his movements, and by advancing into the very heart of the country which he invaded, they hoped to draw him on into the interior of Russia, far from his resources, and to places where he could not support his army by plunder and contributions. They also anticipated the effects of a Russian winter, if he should be mad enough to continue in it till this season. In order that this plan should be carried into complete and successful execution, it
was necessary that the inhabitants and soldiers of the invaded country should be such as the Russians were, both of them incapable of being seduced by the arts of the French,—even deaf to the promises of liberty, when that blessing was to come from an enemy. In short, the attachment, both of the Russian peasantry and the Russian army, to their Emperor and their country is so strong, that no temptation, no difficulty, can possibly shake it. But though the plan of the Russians was to draw Bonaparte into the interior of their vast, desolate, and barbarous empire, yet they at the same time determined to oppose him wherever they could do it with advantage, and thus weaken him as he advanced.

Such was the plan of the Russians, and they acted up to it with a patriotic perseverance which does them infinite honour. Bonaparte, indeed, was successful, in so far as driving back the Russians and advancing constituted success: he even succeeded in dividing one of the Russian corps from the main army. But as he advanced, he found no signs of intimidation on the part of the Emperor; no proof of attachment or submission from the people; and he must have been sensible that he was leaving his resources far behind, while he could not hope for regular and sufficient supply from a country never well cultivated or fertile, and now laid waste and deserted by the inhabitants as he proceeded. Those discouraging circumstances, however, did not appear so manifestly while he was in Poland and Lithuania, as the inhabitants of these districts, not attached to Russia, and regarding Bonaparte as their liberator, received him with gratitude and joy. On the 28th of June, he entered Wilna, which he did not leave till the 17th of July. His transactions during this stay are not clearly known; but though he was stationary, the different divisions of his army were on the advance. His plan now began to unfold itself, and he seemed to be aiming at once on the destruction of the main Russian army, and the occupation of Petersburg. On the latter enterprise, a corps under the command of Marshal Macdonald was sent. The rest of his army followed the line of the retreat of the Russians.

At Drissa, the Russians had an entrenched camp; but as the corps which Bonaparte had succeeded in separating had not yet come up, this was abandoned, and a position at Witebsk occupied. On the 24th of July, they arrived here, one of their corps having been previously dispatched to the north to cover Petersburg. On the 25th, 26th, and 27th, three battles took place; the Russians fought obstinately; and having succeeded in weakening the French, again retreated.

In the mean time, Marshal Davoust, who had been sent after the Russian corps which was separated from the main army, came up with it, and brought it to action: but the result was not favourable to him, and he found himself so weakened that he was not able to prevent its rejunction. The French army which had marched on the route to Petersburg, was equally unfortunate. The plan of its general was to cross the Dvina, come round upon Riga, and thus cut off the communication with the capital. But in consequence of his losses on the 30th and 31st of July, in two very severe actions, he was obliged to recross that river, and the communication between Petersburg and the main Russian army was thus rendered secure. This army, on leaving Witebsk, retreated on Smolensk, Bonaparte still following them; but on account of the nature of the country, and the extreme difficulty of procuring provisions, he was obliged to disperse his different corps at a considerable distance from each other; he also began to experience another serious inconvenience. In other countries which he had invaded, he had been directed in his march, either by accurate maps, or by the information and guidance of the peasantry; but of this part of the Russian empire, there were no maps sufficiently accurate and minute for his purpose, and the peasantry fled at his approach. He thus advanced, ignorant of his route, and of the situation of his adversaries; and from these causes we find, even in the French bulletins, frequent acknowledgments that disastrous surprises took place. But the army suffered most from fatigue and want of provisions; so much so, indeed, that Bonaparte could not move from Witebsk till the middle of August. From this place he advanced to Smolensk, where he at length hoped to bring the Russians to a decisive engagement. They did wait for him here, but only till they had acted on their regular plan; for after having fought the French with great steadiness, and caused them great loss, they again retreated. Soon afterwards, the command of the grand Russian army was given to Kutusoff, who resolved to improve upon the plan of his predecessor, the Baron de Tolly, by offering a more steady and persevering resistance to the enemy, but still retiring, even after success. On the 18th of August, the French having thrown a bridge over the Borysthenes, crossed that river; and as it was now evident that the Russians meant to retreat in the direction of Moscow, Bonaparte endeavoured to cut them off from that place. In this attempt, however, he did not succeed at this time; and the divisions who were employed on this occasion suffered severely. The Russian generals continued his retreat, till he arrived at Borodino, within a short distance of Moscow. Here the position was so extremely favourable for defence, though it did not cover the capital, that he resolved at length to try the issue of a general engagement with the French. Bonaparte, though he could have reached Moscow without fighting, preferred attacking Kutusoff. The force on each side was nearly equal; amounting to about 140,000 Borodino men; for already the French, by the obstinacy of Russian defence, the incursions of the Cossacks, who continually harassed their march, and the losses occasioned by disease, fatigue, and inadequate food, were reduced to this comparatively small number. The position of the Russians, naturally very strong, had been further strengthened by art; their line was protected by two heights, crowned with redoubts at 100 paces from one another; and the ridge was covered with artillery and infantry, for the purpose of supporting their centre. At six o'clock in the morning of the 7th of September, Bonaparte commenced the attack, by attempting to carry the Russian line by main force. The contest was murderous, but the issue unfavourable to the French; and while they were thus occupied, nearly 30,000 Cossacks cut their way into the centre of their camp, carrying confusion, disorder, and dismay, along with them. Bonaparte next ordered that an attack should be made on the heights; and this, after a most sanguinary contest, was partially successful. While these operations were going on in one part of the army, in another part the Russians were the assailants, and drove back the French. Thus the engagement continued with varying success, till night; and though the French were undoubtedly the whole part of the field of battle; yet, in other parts, they were so much beaten, that Bonaparte judged it prudent to draw off his forces.
The Russian general, having thus succeeded in the great object of the campaign, which was to weaken Bonaparte as much as possible, and at the same time to draw him farther into the country, resolved to abandon Moscow to its fate; and this he was the more disposed to do, as the French army after the battle had been reinforced by a corps under Marshal Victor. Bonaparte now saw the capital of Russia within his reach: and though, by the persevering refusal of the Emperor Alexander to treat, he could hardly expect that the possession of it would bring him to terms, yet he looked forward to it as a place of refuge against the severity of the Russian winter, and as the probable deposit of those articles of provision and refreshment, which his army so much wanted. How great then must have been his mortification and disappointment, when, just as he was entering Moscow, he beheld the flames consuming it! The patriotic governor, and no less patriotic inhabitants, nobly sacrificing their venerated city,—their own homes and property,—rather than that the French should derive any advantage from them.

Of the hopelessness of the situation of Bonaparte and his army, at this time, it is scarcely possible to form an idea: he had indeed conquered Russia, if that could be called conquest, which consisted in advancing into the interior of a country; after most severe and obstinate fighting; where no provisions were to be had, where supplies failed on his approach, and in reaching the capital of that country, only to behold it in flames. The winter was approaching,—a Russian winter,—he was at the distance of 500 or 600 miles from a hospitable climate, and from his resources; on all sides of him were an enraged peasantry, and an army accustomed to the climate, acquainted with the country, and constantly increasing; whereas his army could receive no increase; nor even continue at its present force, diminished as it must daily be, by fatigue, want of provisions, and the severity of the climate. In this dreadful crisis, Bonaparte continued his usual and favourite system of deception. His bulletins, calculated to deceive his subjects, represented the climate of Russia as mild, the stores of Moscow as ample sufficient for all the wants of the army, and the peasantry as rejoicing in the presence of their invaders. Notwithstanding the approach of winter, he lingered in Moscow, in the vain hope that the Emperor Alexander would agree to peace; but he knew too well that the possessor of the ancient capital of Russia was in fact at his mercy; and he positively refused to negotiate.

At length, the proud and obstinate spirit of Bonaparte gave way, and he resolved to retreat; but even this was represented in his bulletins, as only a lateral movement on Petersburg. His resolution, however, was formed too late: he left Moscow, as soon as ever his army was refreshed and prepared for retreat, and before the approach of winter was so near, he might have escaped the unparalleled disasters which befell him; but by delaying it till the middle of October, he rendered it impossible for him to proceed far, before the severity of a Russian winter would attack his troops, while he gave time for the enemy to complete their operations for harassing them. These preparations, indeed, were extensive. On every side the Russians were collected; and especially immense numbers of Cossacks, admirably calculated for this mode of warfare.

Before Bonaparte could leave Moscow, it was necessary to drive back the grand Russian army, which occupied the Kalouga road, by which he meant to proceed: this Murat, who commanded the cavalry, attempted; but he was defeated with dreadful loss. In consequence of this defeat, Bonaparte was compelled to abandon his intention of retreating by the route of Kalouga; but in order to deceive Kutusoff, he began his march in that direction, and afterwards turned off on the road to Smolensk. He himself marched with the van of his army, surrounded by the Imperial guards: the Viceroy of Italy brought up the rear.

As soon as Kutusoff was informed of the route which the French army had taken, he began his march in a parallel line, leaving it to the other divisions of the army, and especially the Cossacks, to hang on the rear and the flanks of the enemy. No words can paint the misery and sufferings of the French during this retreat. "Scurvily had they worn out by a day's march, along broken and deep roads, during which they were constantly obliged to be either on the alert, or actually fighting, lain down on the wet and cold ground, to obtain a little rest or sleep, when the Cossacks rushed into their camps, and before the men could prepare themselves for resistance or defence, many were killed—all were thrown into confusion and dismay, and their artillery and stores carried off." While they were thus exposed to the sudden and irregular attacks of the Cossacks, Kutusoff seized every opportunity of bringing them to battle. On the 24th of October, he attacked them most vigorously; the French fought with desperation, but their strength was at length worn out, and they were compelled to retreat with the loss of 16 pieces of cannon. After this defeat, Bonaparte pushed forward before his army towards Smolensk, the Imperial guard alone accompanying him in his rapid and disgraceful flight.

It is impossible to describe the losses and sufferings of the French till they arrived at this place. About the beginning of November, the Russian winter set in with more than usual severity, and on the first day of the frost nearly 30,000 horses perished. "All possibility of carrying forward their artillery was now at an end: the spirits of the soldiers completely deserted them; they crawled on, exposed to the most dreadful cold, exhausted with fatigue and hunger, emaciated and almost naked. The road was literally blocked up with the dead and the dying; they had no power to defend themselves against the Cossacks, who constantly hovered round them; they had no inclination to do it: death to them would have been a blessing: at the sight of the Cossacks they hoped their miseries would soon be terminated; but their enemies were not so merciful as to put them to death; piercing them with wounds, stripping off the little covering they had, they left them in the snow, there bleeding and naked, to the rigours of a Russian winter. Whenever the French entered any village, where there was the least chance of rescuing or food, they exerted their little remaining strength, and crawled on their hands and feet to seek it. Frequently, just as they had stretched out their hands to seize a little food, or reach the threshold of a wretched hut, under which they looked for shelter from the weather, perhaps for a few minutes sleep, the remnant of their strength failed them, and they expired."

It may well be conceived, how little able such an army was to resist the regular Russian troops; yet occasionally despair lent them strength, and they fought obstinately, but never successfully. In addition to their miseries, they lost all confidence in Bonaparte, and in fact could no longer be said to compose an army; ignorant of the roads, and afraid to meet with the Cossacks, they wandered in all directions, or actually laid
they themselves down to die. Every day witnessed the diminution of their numbers, by defeat or the effects of famine and the climate; but their most serious loss took place at Krasnoi, where Kutusoff completely routed them; the division of Davoust, nearly 24,000 strong, being for the most part, killed, wounded, or taken prisoners. A few days afterwards, the division of Ney attacked the Russians, but they were repulsed, and being surrounded, 12,000 laid down their arms. But it is not possible, within our limits, to particularise all the disasters to which they were exposed: The passage of the Berezina, however, must not be omitted; here the slaughter was dreadful, for Bonaparte, after he had crossed it with part of his troops, perceiving that the Russians were close behind him, ordered the bridge to be set on fire, and thus exposed his soldiers to most dreadful destruction, both from the flames and the enemy. After this their retreat to Wilna was not so disastrous: before, however, the troops arrived there, Bonaparte left them, travelling in a sledge incognito, along with Caulincourt, and returned to Paris on the 10th of December. Murat was left in command; but he soon followed the example that had been set him; and the command of the disorganized remains of this once most numerous and formidable army devolved on the Viceroy of Italy. The loss of the French in this campaign cannot be estimated lower than 500,000 men; and this loss was entirely occasioned by the mad and obstinate ambition of Bonaparte; for when we recollect that, at the close of summer, he led an immense army into the very heart of Russia—into a country, in which winter reigns with most intense and unbroken severity for half the year; that in front, and rear, and both sides of this army, we immersed bodies of troops inoculated to the climate, and cutting off all chance of procuring provisions; and that this army, when compelled to retreat, had to march upwards of 500 miles, without shelter, almost without food and clothing, on roads broken up, or rendered nearly impassable by the snow, exposed to the most intense cold, and harassed night and day by clouds of Cossacks, we may be astonished at the insane rashness of Bonaparte, but we cannot be surprised that nearly the whole of his army was destroyed."

That division of the French army which marched on the road to Petersburg, shared the fate of the main army; for, not being able to gain possession of Riga, and being continually opposed by the Russians, while Bonaparte would not allow it to retreat, till he himself had retired, it suffered nearly in an equal degree, both from the enemy, and the severity of the climate.

It has already been stated, that the French bulletins represented Bonaparte’s advance into Russia as the conquest of that country, and his possession of Moscow as the completion of his triumph. The real state of the case, however, was known at Paris; and even he, soon after he left Moscow, could no longer conceal it. His twenty-ninth bulletin exposed his disgrace and disasters in more complete nakedness to the citizens of Paris, than they had ever before been witnessed, believed, or hoped, that his situation was even more desperate than he admitted. A report of his death was spread. Part of the national guard betrayed symptoms of open opposition to his government; but the plot, not being laid with judgment and caution, was detected, and the ringleaders apprehended. The intelligence of it is supposed to have contributed to induce Bonaparte to quit the army, and return to Paris.

As the yoke of Bonaparte had been impatiently borne by the Prussians, the defection of a corps of them, which had been attached to the French army that marched on the road to Petersburg, was not surprising. Maconald, who commanded this army, being thus weakened, and being, moreover, harassed by the Russians, retreated in great disorder; abandoning Koningsberg to its fate, and directing his flight to the Vistula. Across this river the remnants of the French also fled, pursued by their unwearied and implacable enemy.

The king of Prussia, being still in some measure in the power of the French, knew not how to act. His interest, as well as his inclination, led him to justify the defection of his generals, and openly to abandon the French; but he was apprehensive, that if Bonaparte recovered from his losses, he might again be reduced under his power. In these circumstances, on the 15th of February 1813 he made a proposal for a truce, on condition that the Russians should retire behind the Vistula, and the French behind the Elbe, leaving Prussia entirely free from foreign occupation. To this proposal, however, neither party agreed. In the mean time, Bonaparte was deserted by the Austrian auxiliaries, who, indeed, had been of very little service during the campaign. The French still continued their retreat; for a short time they appeared as if they would have made a stand at Berlin; but finding the people of Prussia decidedly hostile to them, they quitted that city on the night of March 3d, and the Russians entered it on the following morning, when they were received as friends and deliverers. The French, on leaving Berlin, retreated on the line of the Elbe, towards Magdeburg, where they concentrated their force, and strengthened themselves by drafts from Dresden and Leipzig—the king of Saxony still adhering to their cause. On the 2d of April, the Russians and Prussians first fought together against the French, in the vicinity of Luneburg: the combat was long and sanguinary, but a complete victory was obtained by the allies. The Russians at this time were divided into three armies; one had crossed the Elbe, in order to drive the French towards the Maine; the second was employed in the siege of Dantzic and Thorn; and the third was posted at Custrin and Dresden; the Prussians were distributed in Saxony, Berlin, Hamburg, and Rostock, and also invested Stettin. The Crown Prince of Sweden, who had long promised his assistance to the allies, was expected at Stralsund, to take the command of 50,000 men. From this account of the extent of country over which the allied armies were spread, may easily be collected the loss of territory which the French had sustained.

Notwithstanding this loss, however, and the still more important loss of his best soldiers, and the blow which has been given to his military reputation, Bonaparte resolved to hazard another campaign; for this purpose he exerted all his activity and vigour in calling forth the resources of France, in order again to place his army on a formidable footing. By a senatus consultum of the 11th of January, 350,000 men were placed at his disposal; and shortly afterwards, in the annual expulsi, a very flattering account of the state of the French empire was published, in which its population was rated so high as 42,700,000. At length Bonaparte having appointed the Empress Regent during his absence, set out for the army on the 5th of April, and arrived at Mentz on the 20th. This army consisted of 12 corps, besides the Imperial guards: the different divisions were directed to march in such directions, as to form a junction near Jena and upon the Saale. The
head quarters of the Russian army, now commanded
by Witgenstein, in consequence of the death of Kutu-
ssoff, were to the north of Leipsic; the Prussians, under
Blücher, were to the south of that city.

The first battle was fought in the plain of Lutzen.
It was brought on by the Russian general, who wished
to prevent the junction of the different divisions of the
French army. The Prussians, eager to avenge the
wrongs their country had sustained from France, began
the contest; and it soon became general along the line.
The villages in front were several times taken and re-
taken, and the action continued with great carnage till
seven of the evening of the 2d of May. The allies kept
possession of the field; the 3d of May passed without
fighting, and on the 4th Bonaparte retreated. But his
retreat was not continued far; for the allies, though vic-
torious, had so weakened themselves by their victory,
that they could not oppose the advance of the French
to the Elbe, which river they crossed at Dresden on the
6th and 7th; and at this place Bonaparte fixed his head
quarters. The King of Saxony having now joined the
French with his forces, the allies continued to retreat,
and took up a position on the heights overhanging the
Spree, with the centre of their front line behind Baut-
zeu.

Here Bonaparte resolved to attack them, with his
main army in front, while the divisions of Ney, Lauris-
ton, and Regnier, turned their right. The latter part of
this plan was foreseen, and frustrated by the Russian
General, who ordered these divisions of the French to
be separately attacked; this took place on the 19th.
At four in the morning of the 20th, the grand attack
by the French main army commenced; and after seven
hours hard fighting, they so far prevailed, that the allies
were obliged to fall back to Hochkirchen. On the 21st
they were again attacked in this position; this battle
was still more obstinately contested than the former;
but it also ended in the allies again retiring, but in
good order, and presenting a formidable front to the
French. The track of their retreat was towards Sile-
sia, the capital of which was entered by Lauriston on
the 1st of June.

In consequence of the necessity under which the al-
lies were placed of calling in all their separate corps to
make up for their losses, or to put them out of danger
from the advancing foe, Hamburgh was evacuated by
them; and after a short time, and an ineffectual resis-
tance, again occupied by the French.

Bonaparte had hitherto been successful, and had driven
the allies before him; but his successes and his ad-

The Emperor of Austria joins the Allies.

vance had been dearly purchased: he therefore listened
to the Emperor of Austria, who offered his mediation.
In consequence of it, a cessation of hostilities took place,
and it was agreed that a congress should be held at
Prague. But this congress produced no pacific result;
and the Emperor of Austria, from a mediator, became
an enemy to Bonaparte, as soon as he saw that he was
not sincerely disposed for peace. The Crown Prince of
Sweden also had by this time landed in Germany; so
that the enemies of Bonaparte were greatly increased.
The immediate vicinity of Dresden was the principal
scene of the most important actions, all of which termi-
inating in favour of the allies, their advanced guard
camped on the heights above that city on the 26th of
August. On the following day, the French aban-
donned their ground before Dresden, and withdrew into
the suburbs, and their different works, which they had
rendered extremely strong. Against them, however,
though estimated at 130,000 men, thus defended, the
allies resolved to move: but their enterprise was un-
successful; and on the following day, the 28th of Au-
gust, the French became the assailants, the allies oc-
cupying a very extended position on the heights round
the city. In this engagement, General Moreau, who
had come over from America to oppose Bonaparte, was
mortally wounded. The result of it was, that the allies
retreated in the evening, having sustained a very con-
siderable loss. They were pursued by a large division
of the French under Generals Vandamne and Bertrand;
who were at first successful, but being unexpectedly
attacked on all sides by fresh corps of the Austrians
and Prussians, Vandamne and 10,500 of his men were
taken prisoners.

The allies were also successful in Silesia, the reco-
very of which from the French was entrusted to Blu-
cher. Having defeated Marshal Macdonald, and taken
18,000 prisoners, on the banks of the Katsbach, on the
2d of September, he encamped near Goltitz, and in
an address to his troops, congratulated them on the
deliverance of Silesia from the enemy.

On the 6th of this month, the Crown Prince of Swe-
den having collected the Swedish and Russian armies,
was informed that about 70,000 of the French, under
the command of Ney, were in full march upon Juter-
boch, in order to attack a very inferior corps stationed
there. He immediately ordered the Prussians under
Bulow to support this corps, while he advanced as
quickly as possible. The Prussians fought nobly against
much superior numbers; and as soon as the columns
of the Prince's army began to appear, the French re-
treated. In this action they lost nearly 18,000 men, and
80 pieces of cannon.

The whole of the allies now approached Dresden in
different directions; but Bonaparte, not cured of that
obstinacy which had occasioned the ruin of his army at
Moscow, persevered in remaining in Dresden till he found
that the allies, by directing their principal efforts towards
Leipsic, would completely cut him off from France, un-
less he quitted it. On the 7th of October, therefore,
he left Dresden in company with the King of Saxony,
and took up a position in the neighbourhood of Leipsic.
About this time, he was deserted by the King of Bav-
aria, who ordered 55,000 of his troops under General
Wrede, to act with the Austrians. The allies having
collected their respective armies around Leipsic, resolved
to attack the French in various points. Several very
severe battles took place in consequence of this, in all of
which the French were defeated; and at length they
were obliged to concentrate their whole force in the in-
mediate suburbs of the town. On the 16th of October,
the grand army of the allies made a general attack to
the south of it; but after a dreadful slaughter, they
could not succeed in dislodging the French. The 17th
was chiefly occupied in preparing for a renewal of the
contest. On the morning of the 18th, the different ar-
nies of the allies advanced from the villages round
Leipsic, for their grand attack on the city. During the
Leipsic battle, some Saxon and Westphalian regiments abandon-
ed Bonaparte, and went over to the allies. Few contests
are on record, that have been more dreadful or more
decisive than the battle of Leipsic; the result of which
was, that the French lost, in killed, wounded, and pris-
oners, 40,000 men, and 65 pieces of artillery: seven-
teen German battalions also deserted from them and
joined the conquerors. On the morning of the 19th,
the King of Saxony sent a flag of truce to the Emperor.
Bonaparte arrives in Paris.

On the 14th of November, he replied to the address of the Senate in language of apparent frankness, acknowledging his disasters, but appealing to the French nation for support under them. Two decrees were immediately passed, one imposing additional taxes, and the other ordering a levy of 300,000 conscripts, as the enemy had invaded the frontiers on the side of the Pyrenees and the north, and as those of the Rhine and beyond the Alps were threatened. The natural effect of his reverses now began to appear: a revolution broke out in Holland, which, being assisted by the English, terminated in separating that country from France. Hanover also was entered, and liberated by the Crown Prince of Sweden. Bremen and Emden were recovered. The Viceroy of Italy, unable to cope with the Austrians, abandoned Trieste and the Dalmatian coast; and Dresden and Stettin, with their numerous garrisons, surrendered to the combined forces.

Bonaparte tries in vain to raise the French. But the allied sovereigns, who had assembled at Frankfurt, published a declaration on the 1st of December, laying open their views with regard to France. Against that country they did not make war, but against the insatiable ambition of Bonaparte, to whom they had already offered fair and honourable terms of peace, but in vain. It was for the advantage of Europe, that France should be independent and great. This they did not wish to prevent; so far from it, if they succeeded in their plans, they would welcome it; but they were also determined that their states should, for the future, be also independent,—no longer liable to the tyranny and ambition of Bonaparte. The last twenty years had witnessed unparalleled calamities heaped on Europe: They trusted they had now in their power to put an end to these calamities, and they resolved to do so. This declaration, so moderate and liberal, displeased Bonaparte. There was nothing in it on which he could lay hold, as manifesting an intention to injure the honour or weaken the just power of France; he therefore replied to it in general and ambiguous terms, in his speech before the Legislative Body on the 19th of December, maintaining, that the allies alone were to blame if peace had not been concluded, as he had adhered to their preliminary basis; adding, however, that if peace were made, it must be on terms consistent with honour.

who invade France.

In the month of December, the allies crossed the Rhine and invaded France. This operation was performed with little or no opposition at various points, not a single French army appearing in the field to defend the frontier. The strong fort of Hünigen, in Alsace, was invested, and the allied troops spread over that province and Franche Comté. Under these circumstances, Bonaparte issued a decree on the 26th of December, announcing the mission of senators, or councillors of state, into the military divisions, to act as commissioners extraordinary, armed with powers to provide and organize the means of defence; and thus, in fact, suspending all the magistracies, and other authorities in the country, and extending the immediate agency of military despotism to every part. There were thirty commissioners appointed, who were to be attended by as many law officers. These efforts, however, were unavailing, and their result proved at once, that the French people were wearied out with calamity, and were disposed to regard the allies rather as friends than foes, and that the authority and power of Bonaparte were drawing to a close; for he must have expected, either that the people would have risen of their own accord, when called upon to defend their country, or that he possessed the means of compelling their services on this occasion; neither of which took place to any considerable extent.

We must now turn to the affairs of the peninsula. In Affairs of December 1812, the French main army, now under the command of Drouet, was in the neighbourhood of Salamanca and Valladolid, occupying various posts on the line of the Tagus. Joseph Bonaparte was at Madrid, and Soult had his headquarters at Toledo. Thus all the central parts of Spain were in the power of the French. Lord Wellington was at Freynada, on the frontiers of Portugal, about the middle of March; nearly all the French troops were withdrawn from La Mancha, and the army of the south was concentrated between Talavera, Madrid, and Toledo,—Joseph Bonaparte having quitted Madrid. These movements, and others connected with them, indicated that their plan was to retire from the central provinces, and take strong positions in the north and north-east. In the south-east of Spain, Suchet had been obliged to quit Valencia, in consequence of some successes gained by the Anglo-Sicilian army under Sir John Murray. In April, the main French army was still occupied in moving from the Tagus to the Douro; but their force was much weakened, as, during February and March, nearly 25,000 men had been sent into France, to assist Bonaparte in his German campaign.

These movements and indications of the French, determined the plan of Lord Wellington. On the 26th of May, he fixed his headquarters at Salamanca. Here a slight skirmish took place. His army afterwards continued to advance to Toro, the French persevering in their plan of evacuating the central provinces. On the 7th of June, Lord Wellington crossed the Garonne, and, after reconnoitering a strong position which the French occupied at Burgos, had, however, they did not defeat, but retired with their whole force in the night, marching towards the Ebro, on the road to Miranda. On the 14th and 15th Lord Wellington crossed that river, and continued his march towards Vitoria.

Joseph Bonaparte was now the nominal commander of the grand French army; but the actual command was vested in Marshal Jourdan. The army consisted of the whole of the armies of the south and the centre; of four divisions, and all the cavalry of the army of Portugal, and some troops of the army of the north. On
the 19th of June, it took up a position in front of Victoria. On the 20th Lord Wellington's army halted, and his Lordship reconnoitred the French. On the 21st he attacked them, and gained a most signal and glorious victory. The retreat of the French was so rapid, that they were unable to draw off their baggage and artillery, the whole of which fell into the hands of the victors. The French retreated by the high road to their own country, first to Pampluna, and on the 25th by the road of Roncesvalles into France; a brigade of the army of Galicia, under General Castanos, driving them across the Bidassoa, the boundary river, over the bridge of Irun.

Marshal Suchet was still in the south-east of Spain, where Sir John Murray was employed in besieging Tarragona. As the relief of this place was of the utmost importance, the Marshal collected about 20,000, and advanced towards it. Sir John Murray, not deeming himself sufficiently strong to meet his opponent, reembarked with so much precipitation, as to give rise to much complaint and censure of his conduct.

In the mean time, though the main French army had actually evacuated the Peninsula, and entered their own country, part of their troops still maintained themselves in the valley of Bastia; of which, on account of its richness and strong positions, they seemed resolved to keep possession. Against them, therefore, a detachment of the British were sent, who succeeded in dislodging them. It was now supposed, that the French would retire quietly before their conquerors; but Bonaparte, notwithstanding his reverses in the Peninsula and Germany ought to have taught him the necessity of confining himself to one object, still persevered in his resolution to recover Spain, if possible. For this purpose Soult, certainly his best general, and who had greatly distinguished himself in the south of Spain, was appointed, by an imperial decree, commander in chief of the French army in Spain and the southern provinces of France. He joined the troops on the 13th of July, and on the 24th collected at St Jean the right and left wings, amounting in all to 30,000 or 40,000 men; with whom, on the subsequent day, he attacked the British forces that were posted at Roncesvalles: Having turned their position, they were obliged to abandon it. On the same and the following days, to the end of the month, Soult repeated his attacks; while, on the 30th, Lord Wellington became the assailant, and obliged the French to abandon a position, said by his Lordship to be "one of the strongest, and most difficult of access, that he had yet seen occupied by troops."

The result of all these operations was, that though the French at first succeeded in driving in part of Lord Wellington's army, yet on the night of the 1st of August it occupied the same positions which it had done on the 25th of July. Soult was now posted behind the Puerto. From this position Lord Wellington resolved to dislodge him, by a combined movement of three advanced divisions. One of these, however, being first formed, commenced the attack by itself, and actually drove the two divisions of the enemy from the heights which they occupied. Thus this part of the Spanish frontier was entirely freed from the presence and occupation of the French.

The strong fortresses of Pampluna and St Sebastian still held out. The former was besieged by the Spaniards, but the latter by Sir Thomas Graham. An unsuccessful attack was made on St Sebastian on the 25th of August, which cost the British many lives. This, however, did not deter Sir Thomas Graham from renewing the attack; but the attempt seemed nearly desperate, when the assailants having made repeated but fruitless exertions to gain an entrance, no man surviving the attempt to mount the narrow ridge of the curtain, he adopted the critical and venturesome expedient of ordering the guns to be turned against the curtain, the shot of which passed only a few feet over the heads of the men at the foot of the breach. This manœuvre, joined to the success of the Portuguese in another quarter, decided the fate of St Sebastian. But Soult was too deeply sensible of its importance to permit it to fall, without making an effort to relieve it. He therefore made several desperate attacks on the allied army; but, though several of them were directed against the Spaniards and Portuguese, they repulsed them with great bravery and steadiness; and on the 18th of September the castle of St Sebastian surrendered.

On the 7th of October, Lord Wellington crossed the Lord Wel-Bidassoa and entered France; but he did not commence offensive operations till the fall of Pampluna had decided the fate of St Sebastian. But Soult was too deeply sensible of its importance to permit it to fall, without making an effort to relieve it. He therefore made several desperate attacks on the allied army; but, though several of them were directed against the Spaniards and Portuguese, they repulsed them with great bravery and steadiness; and on the 18th of September the castle of St Sebastian surrendered.

Lord Wellington soon determined on his plan of attack; but the execution of it he was obliged to defer, in consequence of the heavy rains. On the 10th of November, however, the weather proving favourable, he commenced his attack, the object of which was to force the centre of the enemy, and establish the allied army in the rear of their right. The various attacks to accomplish these objects began at day light, and it was not before the rear of the right of the French army was gained. On the next morning they were pursued across the Nivelle, and on the following night they retired to an entrenched camp in the front of Bayonne.

As, however, they still held posts on the rivers Adour and Nive, Lord Wellington caused a series of manœuvres and operations to take place on the 9th, 10th, 11th, 12th, and 13th of December, the result of which was, that the French were driven from most of their positions, and obliged to confine themselves to the vicinity of Bayonne.

In the mean time, Suchet, in the south-east of Spain, seemed resolved to maintain himself, notwithstanding the retreat of the French main army from the Peninsula. Sir John Murray having been recalled, Lord William Bentinck had assumed the command of the Anglo-Sicilian army. His first operation was to resume the siege of Tarragona, which Sir John had abandoned on the advance of Suchet. But the Marshal again advancing with nearly 25,000, Lord William Bentinck was obliged to imitate the example of his predecessor, and retreat upon Cambriety.

By the middle of January 1814, part of the allied army occupied Langres, an ancient and considerable town 100 miles within the French frontier; till they reached it, there was not a single shot fired at them by any body but the military. Bonaparte had not yet quitted Paris, and had not been able to collect any considerable force. The troops he had mustered were under the command of Marshals Victor and Marmont, the former of whom advanced into Alsace, to oppose the Bavarians, under General Wrede; but not being able to cope with
them, he abandoned this province, and retired into Lorraine. Here he engaged the first on French ground, took place: Victor was defeated, and obliged to continue his retreat to Launville. By the middle of January, the Cossacks, who had entered France in great numbers, gave a clear proof, in what a defenceless state it was, by pushing on between Epinal and Nancy, unsupported by any regular troops.

The second French army, under the command of Marmont, was opposed to Blucher, whose troops had crossed the Rhine near Coblenz and Mannheim; but he found it necessary to retreat before the Prussian general, and take up a position behind the Saar. Even here he could not long continue; for by the end of January he had fled to Verdun, while Victor was at Commency; and the additional troops which Bonaparte had placed under the command of Mortier and Macdonald, were at Chaumont and Namur. The allies, at this time, occupied Lorraine, as far as the Meuse, all Alsace, Franche Comté, and great part of Burgundy. Such, however, was the embarrassment of Bonaparte, that he had not yet quitted Paris. Notwithstanding the representations of his force, and the favourable disposition of the French, which were given in the French official newspapers, his means to cope with the allies were so inadequate, that he resolved to sue for peace. The allied sovereigns had taken up their head quarters at Chatillon; and thither Caulincourt, Bonaparte's minister, was directed to proceed. But peace was not expected, even by the most sanguine; for though the allies were sincerely disposed towards it, and the Emperor of Austria was suspected of a leaning towards his son-in-law, which retarded his cordial co-operation with them, yet the character of Bonaparte left no doubt, that his sole object was delay, in order to augment his forces; and that, if he were again successful, his conduct would be as ambitious and overbearing as before. A congress, however, was held at Chatillon, which was attended by the allied sovereigns in person, and by Caulincourt on the part of Bonaparte, and Lord Castlereagh on the part of Great Britain.

In consequence of the rapid advance of the allies, the more young and active members of the Bourbon family left England, and embarked for the continent towards the end of January. This step they took entirely of their own accord, since none of the allied powers had given them reason to believe that they would declare or support Louis XVIII. On the contrary, they had solemnly engaged not to interfere in the internal government of France, and were even disposed to treat with Bonaparte. But the Bourbon princes knew their adherents were numerous in different parts of France, and these they wished to increase and animate by their presence in the capital.

The situation of Bonaparte, already extremely embarrassing, was rendered still more so, by the stoppage of the national bank. By the report of the directors, it appeared that their ready money amounted only to £600,000, which, from the eagerness of the holders of notes to obtain payment, would be exhausted in a very few days. In order therefore to prevent the draining of the bank, it was announced, that whatever number of notes might be presented for payment in the course of the day, not more than the value of £20,000 would be paid; and that no one would be paid, unless he were the bearer of a number delivered to him by the mayor of his quarter. This measure was by no means calculated to remedy the evil effectually; and even as far as it was efficacious, it only produced an evil of greater magnitude, by diminishing the public confidence, and proclaiming to the people, that their just demands on the bank were to depend for payment on the certificate of those who were entirely under the control of Bonaparte.

At length, Bonaparte having appointed Maria Louisa regent, left Paris on the 25th of January. The French armies were retreating from different quarters towards Chalons on the Marne, for the purpose of assembling within the line of the Meuse. The allied armies were concentrating and pressing on the same point. Blucher by the way of Nancy and Toul, and Schwartzemberg, who had the chief command of the Austrian and Russian armies, by Langres and Chaumont. About the beginning of February, these two grand armies came entirely into communication with each other, when two corps of Austrians were placed under the command of Blucher. This general immediately made his dispositions for attacking the French, who rested their right at Dienville, their centre at La Rotherie, and their left near Tremilly. After some partial movements and operations, by which part of the allies got possession of an important position, which Bonaparte in vain attempted to recover, a most desperate engagement took place at La Rotherie. Bonaparte led on his troops in person, and at first was successful; but the allies, fighting under the eye of the sovereigns, were assisted by the example of Blucher, who bore a deadly hatred to Bonaparte, opposed them with superior firmness and perseverance. The battle lasted till ten at night, when the Russians remained masters of La Rotherie, though the French held the ground beyond it, and at midnight, on the 1st of February, were in possession of the heights of Brienne, near which their right had been posted at the commencement of the engagement. Bonaparte, fully sensible of the extreme importance of La Rotherie, made many desperate attempts to regain it, but being opposed by Blucher in person, he was in all of them unsuccessful; and at last he was compelled to retreat with a loss of 40 pieces of cannon, and 3000 prisoners. He retreated first to Troyes, and afterwards to Nogent. On the 5th of February, Marshal Macdonald was defeated by D'York, between Vitrey and Chalons.

The allies followed the beaten and retreating foe as rapidly as they could. On the 7th of February, they entered Troyes, where Prince Schwarzenberg fixed his head quarters, Marshal Blucher being about 20 miles to the north of this town. The French people beheld these disasters of their monarch, and the advance and successes of the allies in general, with equal indifference. Notwithstanding Bonaparte painted in the most dreadful colours the cruelties of the Cossacks, and called upon them to rise in mass to defend their country from these barbarians, they remained unmoved and quiet. The allies did not invite them, much less require them to rise in favour of the Bourbons; and even in some cases, as they were still negotiating with Bonaparte at Chatillon, they rather repressed the loyal expressions of the people, in favour of their legitimate sovereign. As therefore there felt no affection for Bonaparte, and found that the allies performed their promise, in neither forcing the Bourbons on them, nor plundering their country, they gladly remained quiet, and to all appearance, almost indifferent spectators of the great contest that was carrying on in the midst of them.

Bonaparte finding himself unequal to contend with both the allied armies, pursued his usual plan of directing his whole force, first against one singly, in the hope if he succeeded, of overwhelming the other; and as
Blucher had separated himself to a considerable distance from the rest of the allies, Bonaparte resolved to follow him. Before, however, he did this, he made a rapid and unexpected movement to the north of Nogent, where he attacked a Russian corps, and took the whole of them prisoners. On the 14th of February, having joined Marmont, he advanced against Blucher, who was inferior in numbers, and particularly in cavalry, formed his infantry into squares, and retreated. Bonaparte followed him, but notwithstanding his attacks were almost incessant and very desperate, he made little or no impression, not one of the squares being broken. In order to intercept the retreat of Blucher, Bonaparte had ordered a corps of cavalry to push forward and get into his line; but Blucher forced his way through it, by opening a heavy fire of artillery and musketry. At night he reached Etoges, but here he was assaulted by a body of infantry, which had penetrated through by roads on his flanks and rear; he was therefore again under the necessity of renewing the attack, and was again successful. In the mean time, the entrenched camp, which Bonaparte had formed for the protection of his army of reserve at Soissons, was assailed by General Winzingeroede with such impetuousness, that nearly 3000 men were taken, and the town itself was entered.

While Bonaparte was pursuing Blucher, the grand army put itself in motion on the left. On the 11th of February, a division of it carried by assault the town of Sens, 82 miles south-east of Paris, and afterwards joined the Bavarians under General Wrede. Other divisions of the allies advanced nearly in the same direction; so that by the middle of February, they had spread themselves about 40 miles along the course of the Seine. Marshals Victor and Oudinot, to whom the protection of this important river had been entrusted, alarmed at the advance of such superior numbers, abandoned the left bank, and destroyed the bridges; these, however, being soon re-established, Prince Schwarzenberg, the commander in chief of the allies, fixed his head quarters at Bray. The allies, however, had now spread themselves so much, and thereby so weakened their line, that Bonaparte returning quickly from the pursuit of Blucher, gained some advantages over part of the grand army, and in consequence of this the commander in chief united the whole of it behind the Seine. Part of it was posted near a bridge over this river; this Bonaparte repeatedly attacked, but was repulsed three times with great slaughter. As, however, it was of the greatest importance for him to gain this position, he renewed the attack the fourth time, and obtaining possession of the bridge, passed over a considerable part of his army.

Blucher, though he retreated before Bonaparte, no sooner found that his adversary was gone against another part of the allies, than he resolved again to advance; his object evidently being to press on, if possible, to Paris itself. After having prevented Oudinot from crossing the Seine, and obliged Marmont to retreat, even after his junction with Macdonald, he pushed forward in such a manner as to render the allies masters of the whole line of the Marne for above 80 miles. Bonaparte now found himself under the necessity of again turning his principal attention to Blucher; for it is observable, that whenever the French armies in this campaign were commanded by any of his marshals, they were unsuccessful. Bonaparte alone seemed to be able to procure them the chance of success. It was therefore absolutely necessary, that he should march with the utmost rapidity alternately from the grand army of the allies to Blucher, and from Blucher to the grand army. At this time, his object was to prevent the junction of this general with Winzingeroede; but being foiled in his project, he could not retreat without a battle. Between the 4th and the 9th of March, various skirmishes took place between his troops and those of Blucher; on the latter day, the Prussian general determined to give battle at Laon; he was, however, anticipated by Bonaparte, who, taking advantage of a thick mist, attacked his right and centre, and obliged him to fall back to the very walls of Laon. As soon, however, as the most disordered, Blucher's army regained the ground which it had lost; and a severe contest ensued on their right and centre. The most important part of the engagement, however, took place on the left of Blucher's army, which the French attacked under a heavy cannonade. But Blucher immediately reinforcing his left with two divisions, and ordering his whole army to advance, the French were not only repulsed, but actually borne down, and thrown into very great confusion, retreating towards Rheims. In this engagement Bonaparte lost upwards of 70 pieces of cannon; and the number of prisoners was immense.

The negotiations at Châlilon were still going on, the allies, notwithstanding their successes, adhering to their former proposal to treat with Bonaparte as the Emperor of France. When he was unsuccessful, he directed Caulaincourt to listen to their terms, but as soon as ever he gained the most trifling advantage, he displayed his characteristic haughtiness, and actually behaved as if the allies were in his power. He seems, even at this time, to have calculated on the lukewarmness of Austria; and it is not unlikely that the negotiations were kept open longer than they would otherwise have been, and better terms were offered to him, in consequence of the connection between him and the Emperor of Austria. He might be strengthened, too, in this belief, from the circumstance that the Austrian army hitherto had done very little for the common cause, Blucher not having been supported, as he might, and ought to have been, by Prince Schwarzenberg.

At length, however, even the Emperor of Austria was convinced that no peace could be made with Bonaparte; accordingly, on the 18th of March, the final and complete rupture of the negotiation took place. Immediately after this event, Bonaparte directed all his efforts in a most desperate manner against Blucher: for two days he poured his battalions against the immovable army of that general; but finding that he could make no impression, he bent his efforts southwards against the grand army of the allies. On the 21st, the two armies were near, and opposite each other, ready for battle; but Bonaparte, perceiving that he had not the smallest chance of success, moved off his columns on the road to Vitrey. At first he proceeded in a northern direction, but afterwards turned to the east on St Dizier, and thus found himself on the 24th of March exactly where he was on the 26th of January, when he opened the campaign.

Let us now turn our attention to the movements and operations of Lord Wellington. Though his army was in the south of France, yet from the vicinity of its position to the foot of the Pyrenees, the weather was so very unfavourable, that he could not advance till the 23rd of February. His first movement was across the Adour and two other rivers; these were successful; and by the 27th of February, the whole army had taken up operations in the south of France.
France.

Although the position of the French general was very strong, his centre being thrown back, and both his flanks advanced on very commanding heights, Lord Wellington resolved to attack him. His plan was, that Marshal Beresford should turn the right of Soult's army, while the third and sixth divisions attacked his left and centre; but the fourth division, to which the attack on the right was entrusted, meeting with great opposition, and being unable to possess itself of the heights, on which the enemy was placed, Lord Wellington changed his plan, and turned the third and sixth divisions against the right of the French; and thus forced him to abandon the heights, lest he should be completely surrounded. We have been thus more than usually particular in describing the manoeuvres of the British during the battle of Orthes, as they afford a striking proof of the characteristic promptitude and decision of Lord Wellington's mind. While these operations were going on in this part, Soult found his centre attacked and his left threatened, by the British division of Sir Rowland Hill having carried a position on which it appayed: Here, however, the French, having a numerous artillery, made a vigorous and formidable resistance, but the two points of the base line of his position, (for it was in the form of a triangle,) being hard pressed by flank-attacks, and the centre at the same time yielding to the British, he gave orders for a retreat. At first his troops retreated without confusion; but soon disorder spread among them, and they dispersed and made the best of their way, in the same manner as they had done in the battle of Vittoria. In the night they retired across the Adour, the British being so much exhausted that they could not pursue them to any considerable distance that night. On the 24th, however, they continued the pursuit to St Sevre, where General Beresford having crossed the Adour, advanced to the chief town in the department of the Landes. At first Soult retreated in the direction of Bordeaux, but being defeated by Sir Rowland in an attempt to defend his magazines at Aire on the Adour, he changed his route, and retreated in the direction of Toulouse. The main British army followed him, while Sir John Hope began the siege of Bayonne. Such was the battle of Orthes,—certainly one of the most general and hard fought in which Lord Wellington had been engaged since the commencement of the Peninsular war; and it may be added, that not only in the positions which Soult fixed on, but in his conduct during the engagement, he fully made out his claim to talents and perseverance as a military man.

The people of the south of France, notwithstanding all the efforts to represent the English as even worse than the Cossacks, received Lord Wellington and his army as friends; treating them with the utmost confidence and kindness, and evidently showing that they dreaded more from their own soldiers than from them. But though they openly expressed their wish to receive back the Bourbons, Lord Wellington could not proclaim or support their cause, as the negotiations for peace with Bonaparte were still going on. As soon, however, as the city of Bordeaux, which had suffered dreadfully from the revolution, and especially from the measures of Bonaparte against commerce, and in which there were many merchants descended from British families, learned that Lord Wellington had entered France, that Soult was entirely defeated, and that his retreat was towards Toulouse, it determined to declare for the Bourbons. A proclamation to this effect was issued by the mayor; deputys were sent to Louis XVIII., and the British were implored to enter the town, and protect it against the forces of Bonaparte. Lord Wellington accordingly gave directions for part of his army to march thither; and the Duke of Angouleme, who had been for some time with him, though not acknowledged or received publicly, hastened to shew himself to the citizens of Bordeaux. The reception both of the British and of the Duke was most flattering, not only in the town, but in the country through which they passed.

In order to bring the affairs of this part of France to a conclusion, we shall proceed with our narrative of them, premising that about this time Bonaparte had been forced to abandon the government of France, and Louis XVIII. had been acknowledged king. Intelligence of these events had been immediately transmitted to Lord Wellington and Soult, but it unfortunately did not arrive in sufficient time to prevent another battle. Soult had taken up a strong position near Toulouse; on the 8th of April, part of Lord Wellington's army moved across the Garonne; between this river and the canal of Languedoc were the fortified heights, that formed the chief strength of the French position: His Lordship resolved at once to storm these heights, and to turn the right of the enemy, while a tete du post, which they formed on the canal to protect their left, should be threatened. The 9th of April was spent in preparing for these attacks; and on the 10th they were carried into execution. They were in all points so well planned, and so admirably executed, that at the close of the day, the French were completely hemmed in, the allies having established themselves on three sides of Toulouse, and the road to Carcassone being the only one left open. In the night of the 11th, Soult drew off his troops by this road; and Lord Wellington entered Toulouse in triumph the following morning. The close of the campaign in the south of France was marked by one unfortunate event: Before Bayonne, which Sir John Hope invested, the French had a fortified camp, from which they made a sortie at three o'clock of the morning of the 13th of April. The piquets of the British army were driven in, and Sir John Hope, in his gallant attempts to support them, came unexpectedly on part of the French: his horse, which was shot dead, fell upon him; and in this situation he was made prisoner.

Although the allies in the north and east of France had at different times, since the commencement of the campaign, reached within a short distance of Paris, yet they had always been obliged to fall back, in consequence partly of a want of concert, and partly of the wonderful rapidity of Bonaparte's movements, who, with a force decidedly inferior, contrived to pass from one point to another, so quickly and unexpectedly, as sometimes to defeat, and almost always to retard the plans of the allies. As soon, however, as Austria began to act in a more decided manner, he was rendered sensible that his fate could not be much longer protracted, unless he had recourse to some desperate expedient, and that expedient completely succeeded. On the 23d of March, the army of Prince Schwarzenberg directed its route to Vitry, which was in possession of the Prussians. Bonaparte also marched on the same place, for the purpose of uniting with Ney and Macdonald, who were advancing from St Dizier; but the Austrians having reached the place before the French, he threw himself into their rear, while he formed a communication with the army of Blucher. Perhaps at the time Bonaparte found himself obliged to adopt this measure; perhaps
it was the deliberate consequence of a concerted plan; for, whoever has studied his campaigns, must know that he often obtained success, by doing those acts, which, by their very boldness and rashness, so astonished and perplexed his opponents, that, from the effects which they produced on them in this respect, their success in a great measure originated. In this case, the object of Bonaparte, if his measure was preconcerted, which most probably it was, was to get into the rear of the allies; and threaten their communication with Germany. It may be urged that his force was not adequate to destroy the communication; but it must be recollected, that he could receive reinforcements from the garrisons of the towns on the frontiers, provided nothing occurred to prevent his reaching them. It is not likely, however, that he would have abandoned Paris to its fate by thus getting into the rear of the allies, and leaving the road to the capital open to them, had he not believed that the measures taken for its safety were perfectly adequate; for he must have known, that whoever possessed Paris possessed France; so much influence does the capital possess over the provinces. The defence of this city had been entrusted to Marmont, under whose command the national guards, and such other troops as could be spared for this object, were placed. The allies, disregarding the position of Bonaparte in their rear, resolved to strike a grand and decisive blow, by advancing in a body to Paris. There can be no doubt, that in it they had a strong party; even some of Bonaparte's favourites and former advisers, perceiving that their lives and all they had gained in his service were put in extreme jeopardy, by his rashness, resolved to abandon him and court the favour of the allies. The mass of the population too, were at least indifferent about him; they did not, therefore, regard the approach or probable entry of the allies as any evil or disgrace, and consequently resolved not to oppose it, especially as their opposition would have been fruitless. The army of the allies, which advanced against the capital of France, amounted to upwards of 200,000 men. On the night of the 24th, three divisions of the French arrived at Vitry, in the hope of joining Bonaparte there; but they were immediately attacked by the allies, and driven back. This is only one proof among many others, of the imperfect intelligence which the French possessed, even in their own country; and indicated, perhaps, as much as any other circumstance, the decline, not only of the authority, but of the popularity of Bonaparte. In consequence of similar want of intelligence, both respecting the situation of Bonaparte, and the advance of the allies, a convoy, consisting of 5000 men, who were protecting a large quantity of provisions and other necessaries of the utmost importance to Bonaparte, were met by the allies, and after a gallant resistance, compelled to surrender.

By this time Bonaparte had reached St Dizier, but there learning that the allies, uninhibited by his throwing himself into their rear, were still pushing on for Paris, and being moreover ill provided with many necessaries for his army, he resolved to hasten back to the capital as quickly as possible. In this march he was closely followed and constantly harassed by Wimzingerode with 10,000 horse and 40 pieces of cannon. On the 28th and 29th of March, the allies crossed the Marne near Meaux. On the night of the 29th, Mortier entered Paris, where he found about 8000 regulars and 30,000 national guards, under the nominal command of Joseph Bonaparte. This force took up a strong position near the city, with their right on Belleville, and their left on Neuilly. As soon as the allies approached Paris, a flag of truce, with a proclamation, stating that the object of their march was to protect and benefit, not to injure France, and that they hoped to meet with the good wishes and concurrence of every Frenchman in their endeavours to destroy a government, which had occasioned so many evils, not only to the rest of Europe, but to France itself; they did not come to revenge their own wrongs on Frenchmen, nor to imitate the conduct of Bonaparte in every country which he had invaded; they hoped, therefore, that the people of Paris would follow the example of the citizens of Bourdeaux and Lyons, both of which had deserted the cause of a man who had been the curse of France. The flag of truce, however, was refused admittance, and it was therefore resolved to attack the enemy on the heights above Paris. In the centre of the position of the French army on these heights, there were several redoubts, and on the whole line, 130 pieces of cannon. It was planned that the grand army should attack the heights at Belleville, while the Slesian army directed its attack against Montmartre. Marshal Blucher made his own dispositions for the attack.

After an obstinate resistance, the heights of Belleville were carried; and 43 pieces of cannon and a great number of prisoners were taken. Nearly at the same time, Marshal Blucher commenced an attack on Montmartre, from which the French were also driven with the loss of 20 pieces of cannon. Marshal Marmont, seeing no chance of saving the capital, now sent out a flag of truce, proposing an armistice for two hours, and intimating a desire to receive the propositions of the allies, at the same time agreeing to abandon all the positions which he retained without the barriers. To this proposal Prince Schwartzemberg agreed; and the next day, the allies entered Paris, amidst the acclamations of the populace, by whom they were received as protectors and liberators.

Before these events took place, Bonaparte, who had arrived at Fontainebleau, sent Caulincourt to the Emperor of Russia; but the Emperor absolutely declined receiving a message from him. On the 2d of April, the French Senate, which had been assembled on the day before, at the desire of the Emperor Alexander, by Talleyrand, in his character of Vice Grand Elector, passed a decree deposing Bonaparte, and absolving all persons from their oath of allegiance to him as their sovereign. The command of the national guard was entrusted to a French general; but General Sacken was appointed to the military command of the city. A provisional government was established, consisting of Talleyrand, Montesquieu, Jaucourt, Bournonville, and the Duke of Dalberg. As soon as this provisional government was formed, they published an address to the army, telling them that they were no longer the soldiers of Napoleon.

The Emperor Alexander, on his entry into Paris, had issued a proclamation in the name of himself and his allies, promising that the conditions of peace, which they were willing to grant to France, should be no more favourable than they would have been if the people of Paris had adhered to Bonaparte; and that the limits of France, as it existed previously to the revolution, should be scrupulously preserved. This proclamation concluded with calling upon the provisional government to prepare a constitution, which would suit the French people. A constitution was soon framed,
and immediately presented to the Senate; it was read twice, and a commission appointed to examine it. 

On the evening of the 5th of April, the commission made its report, and the constitution was adopted unanimously. By it, Louis was to be chosen sovereign, according to a charter, of which the following are the most important articles: The French call to the throne Louis, the brother of the last king. The executive power belongs to the king. There are to be 150 senators at least, and not more than 200, named by the king; their dignity hereditary; and revenues allotted to them. The princes of the blood and of the royal family are members of the Senate. The legislative body remains as before; it shall not sit for more than five years: The king may convokc, adjourn, and dissolve it; but in this last case, he must call another legislative body in three months at the latest. The king, the Senate, and the legislative body concur in the making of the laws; but those relating to contributions can be proposed only in the legislative body. The sanction of the king is necessary for the completion of a law. The legislative body has the right of discussion; their sittings are open. No member of the Senate or legislative body can be arrested, without a previous authority from the body to which he belongs. The ministers may be members either of the Senate or legislative body. Equality of proportion in the taxes is a matter of right: no tax can be imposed or received, unless it has been previously consented to by the legislative body and the Senate. The law shall fix the amount and the recruiting of the army. The independence of the judges is guaranteed; they are to be for life, and irremovable. The institution of juries is preserved. The king has the right of pardon. The person of the king is sacred and inviolable; but all his acts must be signed by a minister, who are responsible for them. The freedom of worship and conscience is guaranteed. The liberty of the press is entire, with the exception of the legal repression of offences resulting from the abuse of that liberty. The public debt is guaranteed; the sales of the national domain are irrecoverably maintained. No Frenchman can be prosecuted for opinions or votes he may have given. The right of individuals to petition every constituted authority is recognised. The present constitution shall be submitted to the acceptance of the French people. Louis Stanislas Xavier shall be proclaimed king of the French, as soon as he shall have signed and sworn by an act stating, “I accept the constitution. I swear to observe it, and cause it to be observed.” This oath shall be repeated, when he shall receive the oath of the fidelity of the French nation.

At this time Louis was so infirm in his health, that he was not able to leave England immediately; but his brother was appointed Lieutenant-General of France, and repaired to Paris, where he was received with great enthusiasm. He declared his readiness to adhere to the constitution in the name of his brother, although he acknowledged he was not authorised to that effect. As soon as Louis was sufficiently strong, he left England, and on the 3d of May made his solemn entry into Paris. “When he came to the palace of his fathers, a vast crowd collected in the garden, appeared, by their lively acclamations, to solicit the presence of his majesty. The King presented himself in compliance with the wishes of his people. The Duchess D'Angouleme was at his right hand, and the Duke de Berri at his left. Shortly afterwards, the daughter of Louis XVI. made way for Monsieur. The King instantly embraced his brother, and the acclamations were redoubled. The enthusiasm was at its height, when the King, raising his arms towards the crowd, seemed to say, “You are my children, I speak to you from my heart, I embrace you thus.” The people understood him, by crying out, “Long live the King, long live our father.”

On the 30th of May, the definitive treaty of peace was signed at Paris, of which the following are the principal articles: The limits as they existed January 1st 1792, are restored to France. Holland was to receive an accession of territory; but this, as well as the regulation of Germany and Italy, was to be the subject of the deliberations of a Congress to be held at Vienna. All the colonial fisheries, factories, &c., which a she possessed in 1792, except St Lucia, Tobago, and the Isle of France, are restored. She is to erect no fortresses in the East Indies. Two-thirds of the shipping in the harbours of Antwerp and Flushing are to be given up to her. The last article provides for a Congress to be held at Vienna by the Plenipotentiaries of all the powers of Europe, to regulate the arrangements requisite to carry this treaty into full effect.

Before Marshal Marmont agreed to give up Paris, he stipulated with the allies for the personal safety of Bonaparte, and that a provision should be made for his future support. On the night of the 4th of April, a proposal was brought to the allies from Bonaparte, that he would abdicate in favour of his son; but as he was already deposed by the provisional government, no attention was paid to it. He then renounced the sovereignty in the following terms: “The allied powers having proclaimed that the Emperor Napoleon is the only obstacle to the re-establishment of the peace of Europe, the Emperor Napoleon, faithful to his oath, declares, that he renounces for himself and his heirs, the thrones of France and Italy; and that there is no personal sacrifice, even that of life, which he is not ready to make to the interest of France.” Afterwards a formal treaty was concluded at Fontainebleau between him and the allied powers, by which the titles of Bonaparte and of all his family are guaranteed to them during their lives:—the island of Elba is appointed his residence, of which he is to hold the full sovereignty, with an annual revenue of two millions of francs, in rent charge in the great book of France. By the fourth article, the duchies of Parma, Placentia, and Guastalla, were granted to full sovereignty to the Empress, to pass to her son and his descendants in a right line. By the sixth article, a rent charge of 2,500,000 francs was decreed to the branches of Bonaparte's family; and by the seventeenth article, he was allowed to take with him to the Isle of Elba 400 men, and to retain them there as his guard. To all of this treaty the British court refused its sanction, except so far as regarded the arrangements for securing the Italian duchies to Maria Louis, and the isle of Elba to Bonaparte. To this island he was conveyed with as little delay as possible. During his journey, especially in the south of France, he was frequently in danger of his life, from the violent hatred which the mob expressed against him.

Before we proceed to the narrative of events that render even the extraordinary transactions which the Revolution had hitherto given rise to, comparatively tame and common place, we shall offer some remarks, First, on the causes which produced the liberation of the continent of Europe from the dominion of the French, and also the overthrow of Bonaparte; and, Secondly, on the condition and character of the French people at the time when Louis XVIII. ascended the throne.
In the spring of 1812, nearly the whole of the continent of Europe was subservient to the will, and conducive to the interests of Bonaparte. In the Peninsula, indeed, he had not been equally successful; but, at this period, it seemed as if it were only necessary for him to pour into it all his force, in order to reduce it to reluctant and restless submission, and to compel the English to retire to their lines in the vicinity of Lisbon. From the Emperor of Austria, after the humiliation to which he had submitted in the marriage of his daughter to Bonaparte, though no cordial and zealous co-operation could be hoped, no formidible or dangerous enmity was to be feared. The king of Prussia was still more humbled in spirit, and reduced in power. The Emperor of Russia, by the treaty of Tilsit, had delivered himself up, contrary to the interests of his kingdom, to the anticommercial schemes of Bonaparte; and though, at this period, he was beginning to struggle to regain his liberty, yet the probable commencement of a new war, seemed to open up only new prospects of triumph and success to his opponent. For never at any former period was the army of Bonaparte so numerous, or so well appointed in every respect. As soon as he had determined to commence hostilities against Russia, nearly half a million of men were put in motion: Frenchmen, Dutch, Germans, Italians, Poles, and even Spaniards, marched under his banner: Of these dissimilar materials he was the animating spirit; and from the success which had hitherto attended his arms, there was great reason to dread that the empire of Russia would henceforth be obliged to contribute the reluctant service of her sons to the conqueror.

In the spring of 1814, in the short space of two years, Bonaparte was compelled to abdicate the throne of France, and to confine himself to a paltry island in the Mediterranean: his armies, beaten, dispersed, captive, or destroyed, were no longer capable of supporting or protecting him; and France, which for upwards of 20 years had poured her plunderers over the continent of Europe, became the seat of a war, in which she was degraded, conquered,—her capital at the mercy of the conquerors, and indebted for her independence, and her ancient and legitimate territory, entirely to the moderation of those conquerors.

It is not possible to imagine any topic, calculated more deeply to interest the mind, than the contrast not which these events afforded: Were the intervening period not specified, we should be apt to conclude, that such an essential and wonderful change of affairs, could not have been wrought out, but after the lapse of many years. The causes which produced this unparalleled change, in such a very short period of time, are naturally sought for; and, fortunately for the gratification of curiosity, as well as for the more important purposes of history, considered as philosophy teaching by example, these causes are not difficult to be explained.

An observation of the Marquis of Wellesley, in the House of Lords, respecting the character of Bonaparte, will open up to us the most important of these causes. Bonaparte was a man, he observed, who would create unto himself great reverses. In him existed not merely that restless and insatiable ambition, which he possessed in common with most conquerors; but an obstinacy so blind and overpowering, to convert even his great military talents into the causes of his ruin, as scarcely possible to conceive any chain of events, spread even over a period of many months, which could have blasted the power of the conqueror of Europe so utterly and hopelessly, as his own fool-hardiness and obstinacy did in the short space of a few months, during his campaign of Russia. When we say utterly and hopelessly, we mean in reference to his character; for, could experience have taught him wisdom and moderation, not even his losses in Russia could have driven him from the throne of France. But in the campaign of 1813, he again created unto himself great reverses: sanguine, ambitious, and domineering, when partial and temporary success attended his arms; faithless and unprincipled during the negociations into which the allies entered with him, and obstinate when he met with defeat. By advancing to Moscow at the commencement of a Russian winter, and continuing in that city so long, he destroyed nearly the whole of his army. By obstinately clinging to Dresden, till the allies had actually cut him off from France, he brought on the battle of Leipsic, which completed the destruction of a second army. The same scenes were repeated during the short campaign of 1814, when his means were fewer, his opponents more numerous, and his ruin nearer at hand: still he might have been saved,—the allies would have left him on the throne of France; to their terms he listened when unsuccessful; but no sooner had he gained even a doubtful and hard bought victory, but he most foolishly and fatally for himself, but most fortunately for Europe, allowed his ambitious faithlessness to become so apparent, that the allies were convinced that his dethronement was absolutely necessary to the repose and independence of Europe.

But though Bonaparte was the principal cause of his own destruction, yet there were other causes co-operating, which would indeed have been ineffectual of themselves, but which, aided by the man against whom they were directed, became formidable and successful.

At the commencement of the French Revolution, the sovereigns of Europe, for a short time, united against it; but narrow and blind self-interest; mutual jealousy and apprehension; and an imperfect knowledge of the evils with which it was fraught, dissolved the confederacy. Afterwards they were stimulated or goaded by England to an unwilling and unequal contest. At length fatal and dearly bought experience convinced them, that the only means of preserving even the name of independence, and the remnant of power that France had left them, was by cordially and zealously uniting against her. This union, however, could not have been effected during the plenitude of Bonaparte's power; but after that power was reduced by the obstinacy of the possessor, their union became essentially conducive to the restoration of European independence.

At the commencement of the French Revolution, the hatred excited by the tyranny of the French...
with all the insolence and profligacy to which unparalleled success had given rise, was infinitely more oppressive and intolerable. Thus suffering under a common evil, the sovereigns and people of Europe were made sensible, that their interests were more closely connected than they had previously imagined, and were disposed and prepared to co-operate in the recovery of their liberty and independence. An opportunity only was wanting for the spirit of hatred and vengeance against France to burst forth into action; and this opportunity was afforded by the man himself, against whom it was chiefly to be directed.

The events of the peninsular war may justly be regarded as forming another subordinate cause of the destruction of Bonaparte. This war most decidedly proved that the French soldiers were not invincible; that even when opposed by an inferior force, they might be conquered; while the genius and the successes of Wellington proclaimed to Europe, that the most celebrated of the French Marshals had at length met with their master in all the art of war. Thus, even before the Russian campaign, the charm of French invincibility was broken. But the war in the Peninsula gave another cheering lesson to the continent of Europe; for it taught it what could be effected by a people resolved not to submit to their invaders, though that people struggled under the disadvantages of a wretched government, and received little assistance even from their own regular army.

Such appear to have been the principal causes which led to the liberation of Europe.

The condition and character of the French nation, at the period when Louis XVIII. ascended the throne, is an object of investigation, not less interesting or important than that which we have just been examining.

It was supposed by many, that the reverses of Bonaparte in Russia, and the dreadful misery which, by his ambition and obstinacy during that campaign, he had inflicted on his surviving soldiers, would have completely rooted out their confidence and attachment to him. So far, however, it was this from being the case, that even the additional proofs of his falling fame and fortune, and the additional experience of misery, were not materially equal to the impression made by the campaigns of 1813 and 1814, neither deprived him of the attachment and confidence of his soldiers, nor materially weakened the military spirit of France. Indeed, at the period when Louis ascended the throne, the military might justly be regarded as the most important and efficient part of the population. They had been so long accustomed to regard themselves as superior to their countrymen, and possessed such a large portion of the esprit de corps, and such facilities of acting in concert, that though forming but a small portion of the population of France, no sovereign could long be safe, who was decidedly unpopular with them. And it was utterly impossible that they could regard Louis with any other feelings but those of mingled contempt and hatred:—of contempt, because his constitutional indolence, increased by the inactivity of age and infirmity, and by the habits of a literary life, rendered him indolent and unfit for a military life;—of hatred, because, had he been inclined and fit for such a life, the very character by which he held his throne from the allies, and the mass of the French people, absolutely forbade him to follow the career of that man, under whom they had been bred. In short, the military were attached to a life of what they called glory, that is, to a life of conquest and plunder,—their thoughts, feelings, and habits, were all moulded in conformity to such a life. But the allies had invaded France, had dethroned Bonaparte, and had seated Louis in his stead, for the express purpose of putting an end to the military career of France. How then could the Marshals, the officers, or the soldiers of Bonaparte be friendly to the reign of Louis?

The mass of the French nation were weary of the reign of Bonaparte, and exhausted by the measures of that reign: They were anxious for peace and repose. Hence they looked forward to the government of Louis with satisfaction and pleasure; not from any hereditary attachment to the family of the Bourbons, nor from any remembrance of what France had been under them prior to the Revolution. Louis was preferred by them to Bonaparte, because under the former they anticipated the annihilation of the conscription, the restoration of peace, and the enjoyment of some portion of civil and political liberty. But it is impossible that they could have freed their minds from all apprehension, that, along with the restoration of the Bourbons, property might be rendered insecure; feudal privileges and tithes might be revived; and those abuses re-established which, in some measure, had driven that family from the throne. By the mass of the French nation, therefore, by all the landed proprietors, by the farmers, and by the peasantry, all the measures of Louis's government would be watched with suspicion and anxiety.

The manufacturing and commercial classes viewed the restored dynasty with less mixed feelings of approval, and with confidence unweakened by doubt or suspicion; for the Revolution had brought to them no peculiar privileges, had freed them from no particular grievances; on the contrary, it had been a constant source of calamity. They therefore hailed the accession of Louis as the commencement of an era most favourable to their interests; and perhaps, less than any other class of the French nation, felt disgraced by the mode in which he had been seated on the throne of his ancestors.

Although the present generation in France has in a great measure grown up during the Revolution, yet there are, in some of the provinces, what may be deemed hereditary adherents of the House of Bourbon; who wished their restoration, not merely from a sense of the evils which the Revolution had entailed on their country, but because they regarded them as having a right to the throne, of such a nature as could not be set aside by any human authority. This class hailed the return of Louis with blind though sincere joy; anticipating the annihilation of all revolutionary principles and measures; the absolute triumph of the principles of pure monarchy; the enjoyment of the King's confidence, and an ample reward for their long suffering loyalty. With sentiments and hopes similar to these, many of the emigrants must have returned to France; fully persuaded that, as the allies had conquered that country and expelled Bonaparte, there could be no obstacle to the completion of their hopes.

Such is a brief sketch of the condition and character of the different classes of the French people at the period when Louis ascended the throne; and this sketch is sufficient to show the nature, the extent, and the immense weight of the dangers and difficulties with which he was encompassed. The manner, too, in which he came to the throne, by the assistance of the enemies of France, of those enemies over most of whom she had formerly triumphed, but who now beheld her prostrate at their feet, could not fail to create something like aversion to Louis, even in the breasts of those who, from loyalty, from interest, or from purer motives, rejoiced at his accession, as consummating the overthrow of Bonaparte; for the love of national glory is so strong in the breast of a Frenchman, as not infrequently to overcome every other principle, sentiment, and feeling.

Louis was by no means equal to the embarrassing si-
When it yet Ney, with this but the military he never could be popular, and even if he could, popularity with them must have rendered him obnoxious to the allies, and the mass of the French nation; yet almost his first measure was to court the marshals and generals of Bonaparte. By a fatal inconsistency, while he courted their support, he lent himself to the intrigues of the emigrants, or at least did not, with sufficient promptitude, put down their extravagant pretensions to their former privileges. Thus he doubly alienated the people at large, on whom alone he ought to have depended for the support of his tottering throne. His policy should have been gradually to have withdrawn the military foundation of the throne, and to have substituted the more legitimate, as well as the more safe, foundation of his subjects confidence and attachment. Such a plan required most consummate prudence and talents, as well as great energy and decision of character, which unfortunately for Louis he did not possess.

Soon after his entry into Paris, he formed his ministry. At the head of it was M. D'Amory as chancelier; Talleyrand was appointed minister for foreign affairs; the Abbe de Montesquieu minister of the interior; and M. Malouet minister of finance. A council of war was also appointed, consisting of 14 members, most of them the principal generals of Bonaparte; Ney, Augereau, and Macdonald being at the head of the list. Shortly afterwards there appeared an official list of 150 noblemen, named by the King, as members of the chamber of peers for life. This list comprehended nearly all the old Dukes, and other chief nobility of the time prior to the Revolution, with some of the new titles; among the latter were Talleyrand, Clarke, Lebrun, Bertherir, Macdonald, Ney, Suchet, Moncey, Marmont, Augereau, and Oudinot. On the 4th of June the parliament was opened by Louis, in a speech too plainly shewing the necessity of paying court to the national vice of the love of glory; for he was particularly careful to impress on the parliament, and through them on the nation, that the glory of the French armies had received no blemish; that the monuments of their valour remained; and that the chefs d'œuvre of the arts would belong to their honour, and the laws, by rights more stable and more respected than those of victory. What may be called the form of the constitution, was not promulgated till the middle of August; it consisted of a body of resolutions, under various titles, according to which the intercourse between the King and the two legislative chambers was to be carried on. The form of the constitution, as well as the spirit of it, bore a considerable resemblance to that of Great Britain; but in some points it differed from it, for the King of France was invested with the privilege not only of proroguing but of adjourning both the chambers. By these regulations, laws might originate in two ways—either by the King sending proposals respecting them to the two chambers, which proposals might be adopted or rejected; or the chambers themselves, separately or jointly, might pray the King to propose a law.

The eighth article of the constitutional charter, by which Louis possessed his throne, had stipulated for the liberty of the press. On the 6th of July, two of his ministers were introduced into the chamber of deputies, to present a law on this subject. The project of the law was divided into two parts; the first respected the publication of works, and the second the superintendence of the press. According to the first, every work of above 30 sheets might be published freely, without previous examination; but the liberty which was apparently given on this part of the project, was in a great measure withdrawn, by the proposal that the director-general of the press might order all writings under 30 sheets to be communicated to him before being printed. The attachment of censors was to be vested in the King. No journals or periodical writings were to appear without the King's authority. According to the second part of the proposed law, no person could be a printer or bookseller, without the King's licence, which might be withdrawn; and all printing establishments not licensed might be destroyed. The project concluded with a proposal that the law should be revised in three years.

This project was referred to a committee, who decided by a mere majority of votes, that previous censorship ought not to serve as the basis of the law. When the report of the committee was brought up, several bold and eloquent speeches were made in favour of the liberty of the press, which seemed to prove that more practicable ideas of the nature and object of government were beginning to prevail in France; but the painful re-collection that the same men who spoke thus freely and warmly on this important topic, gave applause, apparently as zealous and sincere, to the measures of Bonaparte, forced the mind to withdraw from them the rarer and more useful tribute of disinterested patriotism. In the sitting of the 11th of August, the Abbe Montesquieu addressed the chamber of deputies in defence of the plan of the law, which had been submitted to them, conceding, however, on the part of the King, certain amendments, to the effect that no censure should apply to a work exceeding 20 sheets, and that the law should cease to operate at the end of session 1816. After an animated debate, the law, as amended by the concession on the part of the crown, was adopted by the chamber, there being 137 votes for it, and 80 against it.

The only other topic of considerable interest and importance, which came under the discussion of the chamber, related to the restoration of the unsold estates of the emigrants. A law to that effect passed the chamber of deputies by a large majority; it was then carried up to the chamber of peers, where it passed by a majority of 100 votes out of 106 present. On this occasion Marshal Macdonald pronounced a discourse of great effect, at the close of which he announced his intention of proposing a project of a law, the object of which should be to grant life annuities to those of the emigrants, the sale of whose estates had left them unprotected.

The nature of the proposed law was most maliciously misrepresented in one of the Paris journals. According to the statement in it, Marshal Macdonald asserted that the military of all ranks were willing to contribute a portion of their pay to create a fund for the support of the emigrants. The effect, and probably the purpose of this misrepresentation, was to excite the ill-will of the soldiery, already sullen and irritated, not only towards the emigrants, but towards the King and the government. The offending journal was immediately suppressed; but such was either the timidity or the indecision of the government, that in a short time it was again permitted to be published.

On the 10th of December, Marshal Macdonald presented to the chamber of peers a sketch of his system of indemnity for the emigrants: he estimated at 40 millions the amount of confiscations or sales made, and of course the amount of indemnities to be provided; and he proposed to replace the value of the confiscated and sold estates by an annuity of 2½ per cent.

Such were the two principal topics that came under discussion before the chambers during 1814; they were not only important in themselves, but they had a material influence on the stability and permanence of Louis' government; for the very limited liberty grant-
ed to the press alarmed and alienated the republican party, which were now beginning to assume consistency and strength; and the very agitating of the subject relative to the property of the emigrants, created serious and general apprehension in the minds of the very numerous and widely spread class who had purchased confiscated estates. Discontent and dissatisfaction began to manifest themselves in different parts of the kingdom. Among the oppressions from which Louis, or rather his brother, had promised to liberate the French, were the droits réunis, or indirect taxes; but though the minister of finance, and afterwards Talleyrand, officially reported the prospects of France, with respect to the produce of the taxes, and manufactures, and commerce, as very flattering, yet the King could not redeem his pledge that the droits réunis should be taken off. In consequence of which, the collection of them created such serious discontent, that his Majesty was obliged to issue an ordinance, which at once proved the serious nature and the extent of the evil, and the inability or apprehension of the government, to crush it effectually by vigorous measures.

But all these signs of approaching misfortune to Louis, were ambiguous, or trifling, compared to those which might have been gathered from the conduct, the feelings, and the power of the military. To them the King had delivered himself up, even more completely than he had done when he first ascended the throne: Soult was minister of war, and consequently had an opportunity of forming any plans which his former attachments might suggest. He had, indeed, taken the oaths of fidelity to Louis; but weak and credulous must that man have been, who could put faith in the oath of a soldier of the revolutionary school, one of the most fundamental and cherished maxims of which was, that military glory was of such paramount obligation, as to justify any means by which it could be acquired. The King, therefore, had cast himself, bound hand and foot, into the power of his enemies, while he had neglected to make friends of the people.

In the mean time, Bonaparte, in the isle of Elba, was nearly forgotten; when, to the astonishment and dismay, not only of the French King, but of all Europe, he suddenly landed near Cannes, in France, on the 1st of March. The arrangement of the plan, in conformity to which he was invited, or induced to land in France, is not accurately known. The following circumstances, however, are either well substantiated, or highly probable:—Almost immediately after his departure from France, his numerous partisans, especially among the soldiers in the southern provinces of the kingdom, began to talk in mysterious terms of the violet season, and to express a strong wish for its arrival. To those who compared and considered these terms, it was soon evident that Bonaparte was expected in France at the return of the violet season; but it was not easy to ascertain whether this expectation was grounded on any promise he had made, or plan which they knew was forming, or whether it was vaguely taken up by his admirers. The expectation, however, grew stronger and more general as the spring approached; there is good reason to believe that the ministers of Louis were informed of it, and that it would probably be realized: but what measures of precaution could be expected from men who were either leagued with Bonaparte, or who were so ignorant of the state of France, and of the character of the soveraign of Elba, as to see no danger to their soveraign from either?

It is not so easy to trace the framers of the plan for bringing back Bonaparte, or the arrangements that were made for carrying that plan into execution. We know, however, that Louis was disliked, both by the military and republican party; and it is highly probable that the restoration of Bonaparte was planned and achieved by them in conjunction. The former naturally wished for their Emperor, in the expectation that he would enable them to wipe off the disgrace of defeat; the latter wished for him only as a soveraign, who would free them from Louis, and whom they hoped, by the strength their party had acquired, they could afterwards bind down to the observance of a free constitution.

Bonaparte had been attended to the isle of Elba by commissioners from the allied powers; but soon after his arrival there, they all left him except Colonel Campbell, the British commissioner, who seems to have remained, however, not in any official capacity, or directly charged with the custody of Bonaparte. During the temporary absence of Colonel Campbell, Bonaparte sailed from Porto Ferrajo, on the 26th of February, with about 1000 men, very few of whom were Frenchmen, the rest being Poles, Corsicans, Neapolitans, and Elbese. Generals Bertrand and Drouet accompanied him. It was soon apparent, that the soldiers in France, if they did not flock to his standard, would not, however, oppose his progress; and that most of the Marshals were traitors to Louis, to whom they had taken the oaths of allegiance. Massena commanded in the department where Bonaparte landed; but though he issued a strong proclamation against him, he did not march to oppose his progress; on the contrary, it appears that he dispatched some of his troops in an opposite direction from that in which he was advancing. Grenoble was the first military depot and garrison town at which he arrived; here a corps under General Marchand was posted: the general was faithful, but the soldiers, on a short address from him, joined his ranks. So quick and unmolessted was his progress, that on the 8th of March he reached Lyons.

As soon as the intelligence of Bonaparte’s landing was known at Paris, the fatal consequences of Louis having put such implicit faith in his Marshals, were but too apparent. Soult, indeed, as minister of war, issued an address to the army, in which he denounced Bonaparte as a traitor, and as the author of all the calamities of France; and by this very address, and by frequent official notices, he contrived to announce to all France, the progress Bonaparte had made, the little opposition he had met with, and the formidable nature, as well as the probable successful result of his enterprise; while he utterly neglected taking the proper measures to apprehend him, and is even suspected of having stationed different corps in such a manner, as to serve as the protectors of Bonaparte, where the populace might have risen against him. Marshal Macdonald was not faithless to Louis, but he was not active in his behalf; and the troops with whom he marched against Bonaparte refused to act. Of all the traitors to their soveraign, Marshal Ney was the most unpunished: he voluntarily came forward with an offer of his services to take Bonaparte, dead or alive: troops were placed under his command for that purpose: he advanced apparently against him; but on the 14th of March, when Bonaparte had reached Lyons le Saulnier, he joined him, and issued a proclamation to his army, in which he describes the Bourbons as unfit to reign, and recommends his troops to join the great Napoleon.

Under these circumstances, the zeal of the friends of Louis was of no avail. Monsieur and the Duke of Orleans had advanced along with Macdonald to Lyons; but the military were disaffected, and the people either indifferent, and unwilling to expose themselves to dan-
The inhabitants of Marseilles, indeed, offered two millions of francs to the regiment which should take Bonaparte alive; but no regiment moved to obtain the reward.

Louis, finding that the army was decidedly against him, endeavoured to attach the republican party to his interest, by promising them a freer constitution; but, at the same time, he impolitically threatened the French nation with the invasion of 300,000 foreigners, if Bonaparte should triumph. In reality, surrounded as he was by traitors, and destitute of those talents which were so necessary at the present moment, his conduct was undecided and vacillating;—at one moment he threw himself on the loyalty of the nation, and declared his resolution to terminate his career by dying in their defence;—at another moment, he must have irritated, rather than intimidated the people, by threatening them with the return of those foreigners, by whose presence, in their opinion, France had been so much degraded, and from whom she had received that sovereign, who was now about to claim their assistance.

In the mean time, Bonaparte advanced; and his advance resembled a triumph, rather than the invasion of a country under the dominion of another. It does not appear that the troops which were sent against him, or which flocked towards him from all quarters, actually joined him; but they were equally serviceable by their presence, in keeping down such parts of the population as might have been disposed to oppose his progress. Thus, with soldiers preceding, following, and accompanying him, he marched rapidly from Lyons towards Paris. On the 16th of March, his advanced guard was at Auxerre, 40 leagues from the capital. In the evening of the 19th, Louis left Paris; and, at 4 o'clock in the morning of the 20th, Bonaparte entered it. The departure of Louis was unmolested; and, during his journey into the Netherlands, he experienced no insult from the people; and even the soldiery treated him with silent respect.

As soon as Bonaparte landed at Cannes, he issued addresses to the French people and to the army. In these addresses, he assigns as his reasons for returning to France, the degradation which that country had suffered from the allies, and by the presence of the emigrants; those men who, for twenty-five years, had been traversing all Europe to raise up enemies against their country; and he lays down the principle on which the French nation was in future to act;—to forget that they had been masters of nations, but not to suffer any to intermeddle in their affairs. In subsequent official declarations, however, the breach of some of the articles of the treaty of Fontainebleau, by Louis and by the congress of Vienna, was assigned for his having re-claimed the throne of France.

The two great objects to which Bonaparte immediately directed his attention, as soon as he arrived at Paris, were the preservation of peace with the allies; and the complying with the terms on which the republican party had agreed to his return, by decreeing the forms of a free constitution. In reference to the former object, he addressed a letter to the sovereigns of Europe, filled with declaration against the Bourbons, as a dynasty not fitted for the French people, from which therefore the nation had separated herself, calling upon him as their liberator; and with sentimental effusions in praise of peace, which he declared himself most anxious to preserve. Convinced, however, that the allies would not believe his protestations, but were preparing to act most vigorously against him, he had recourse to the usual methods of deceiving the French nation, who were now beginning to be alarmed at the probable consequences of his return, by representing the English as friendly to him, and by fixing the day of the arrival of the Empress, as a proof that the Emperor of Austria would not support the Bourbons.

The most superficial knowledge of human nature will not permit us to believe, that a man of such a decided character as Bonaparte, with military and despotic habits so long indulged and so strongly formed, could, during his short residence in Elba, become a sincere convert to peace and liberty. His declarations, therefore, in favour of both, must be traced to the same motive. Perceiving that war was inevitable, and that the people required a strong stimulus to rouse them, and being under the control of the republican party, he consented to the drawing up of an additional act to the constitution of the French empire. In this, there were certainly many excellent enactments; but even if France had remained at peace, they must, with the habits and feelings of her population, have been completely nugatory. In order to give the appearance of the free and general acceptance of this additional act, and to afford the Parisians a spectacle, a decree was passed, ordering the assembly of 20,000 representatives of the whole people, after the ancient manner of the Franks, in the Champ de Mai.

Bonaparte soon found that his newly acquired power was likely to be shaken, not merely by foreign war, but by internal commotion, while the despotic authority, which he had formerly exercised, was peremptorily denied him by the chambers. Nearly the whole of the west, and many districts of the south of France, were rising in favour of the Bourbons, animated by the presence of the Duke de Berri at Angers, the Duke d’Angouleme on the shores of the Mediterranean, and the Duchess d’Angouleme at Bordeaux; and though these illustrious personages were soon compelled to leave France, yet they had succeeded in raising a spirit of resistance, not less formidable from its extent and union, than from its determined character. In La Vendée, that former abode of loyalty to the Bourbons, a regular and successful warfare in their behalf was carried on.

As soon as the allied powers were informed of the landing of Bonaparte, they issued a declaration, dated the 15th of March, in which he was declared to have deprived himself of the protection of the law; to have manifested to the universe, that there could be neither peace nor truce with him; to have placed himself without the pale of civil and social relations; and to have rendered himself liable to public vengeance, as an enemy and disturber of the tranquillity of the world. Against him, therefore, and in support of the legitimate sovereign of France, they resolved to make war. This declaration was strongly censured in England, as encouraging the assassination of Bonaparte; and though this interpretation was explicitly and indignantly disavowed by the British ministry, yet in the treaty among the allied powers, which was formed on this declaration, it was thought proper to omit these passages. By this treaty, Great Britain, Russia, Austria, and Prussia, agreed each to furnish 150,000 men; and not to lay down their arms until Bonaparte was completely deprived of the power of exciting disturbances. When this treaty was ratified by Great Britain, a declaration was annexed, that there was no intention to interfere in the internal government of France: To this declaration the rest of the allies gave their formal and solemn assent. Even before the treaty was ratified, the allied troops were in motion towards the frontiers of France; and two formidable armies, under the Duke of Wellington and Prince Blucher, were soon assembled in the vicinity of Brussels. The troops under the Duke of Wellington were composed of British, Germans, Dutch,
and Belgians: Those under Blücher, of Prussians and Saxons; but, in consequence of the mutinous spirit of the latter, most of them were sent back into Germany.

The preparations of Bonaparte were by no means commensurate to those of the allies, nor indeed to the means which France afforded; for it appears by the evidence, that, on the 1st of May 1814, the land forces of France amounted to more than 520,000 men of all descriptions, besides 122,597 on half pay, and 160,000 prisoners. By the treaty of Paris, all the prisoners were to be restored; and, before the return of Bonaparte, they all had returned to France, except a few from Russia. Hence it would appear, that there must have been at least half a million of soldiers in France.

How it happened that Bonaparte could avail himself of the services of so few of these, does not clearly appear. It is probable, however, that the exhausted state of France could not bear the equipment and support of a large army; and it is certain, that the republican party were very unwilling to place a numerous army under his control. To this party, he found himself obliged more and more to succumb. When he first reached Paris, his ministers were Gaudin, Maret, Fouché, Davoust, Savary, and Bertrand. Anxious to confirm the idea that he had abandoned his love of conquest, and his despotical habits, Carnot was taken into the ministry, and Lucien Bonaparte was persuaded to leave Italy and come to Paris. But all these pledges of a reformed character, —his repeated declaration, that he would not commence hostilities,—and even the new constitution, and the assembly of the Champ de Mai, failed to stop the progress of the royalists, or to reassure the mass of the people in his behalf.

The manner in which the members of the assembly of the Champ de Mai were chosen, the character of those members, and their number, cannot accurately be ascertained: From the known policy and practice of the French government at all times, as well as from the peculiar necessity which at this period existed, of imposing upon the French nation and the allies, by the appearance of a zealous devotion to Bonaparte, there can be little doubt, that the Assembly of the Champ de Mai was in a great measure got up (to use a technical but expressive phrase) for effect. At the same time, it must be acknowledged, that in many parts of France very liberal, or perhaps licentious, notions respecting liberty again began to prevail; and that from these parts, it is probable, deputies, freely chosen, and anxious to discharge their duty, were sent. On the 7th of June, a few days after the assembly of the Champ de Mai, Bonaparte went in state to the palace of representatives, to open the session of the chambers. The oath of fidelity to the Emperor and the constitution having been taken, he uncouered himself for a moment, covered himself and then addressed them in a speech, of which the most important topics were, the free constitution which France had just received,—the formidable coalition against the independence of the country,—the actual commencement of hostilities, in the capture of a French frigate by an English man of war,—and the assemblages that had been formed, and the communications which were carried on, with Louis at Ghent, in the same manner as with the emigrants at Coblenz in 1792. He concluded, by alluding to the probability, that the first duty of princes might soon call him to fight for the country; that the army and himself would discharge their duty, while he trusted that the peers and representatives would give to the nation an example of confidence, energy, and patriotism, and, like the Roman senate, swear to die rather than survive the dishonour of France. On the following day, in the House of Representatives, bold and unequivocal proofs were afforded, that Bonaparte was not now so nearly so despotic, or so much feared, as before his abdication; and that even the military were regarded with more jealousy, and as subservient to the good of the state. For, on one of the members proposing, that as the title of Louis le dépeché had been given to Louis XVIII. that of Sauveur de la Patrie should be given to Napoleon, he was three times interrupted by calls for the order of the day, and the president at last informed him that he ought to obey them; and on another member moving, that the army had deserved well of the country, the motion was thrown out, on the express ground, that, till the soldiers had benefited the country, they ought not to receive its thanks and gratitude.

Bonaparte still lingered in the capital, notwithstanding war was actually commenced, and it seemed his policy to attack the English and Prussians, before the rest of the allies joined them, or invaded France in other quarters. The cause of his delay is not known; but it probably arose from the unsettled state of the interior of the kingdom, from his apprehensions respecting the republicans in Paris, and from the inadequacy of his means effectually to oppose the allies. That his troops would fight with most desperate courage, he might confidently anticipate; but there were other circumstances, besides their inferiority in numbers, which might damp his hopes: many of those Marshals, who had assisted or participated in his victories, were either along with Louis, or were too coldly and equivoqually of his party to be trusted. Among the former were Berthier,—his most intimate and longest tried friend and companion, and Marmont;—among the latter were M'Donald, Ney, who might seem to have deserved his confidence, by his most proffigate treachery to Louis; was not with the army collected on the northern frontier to oppose the Prussians and English; nor had he hitherto received any intimation that he was to be employed: and even Soult had no distinguished command assigned him. The force which Bonaparte had collected for the defence of the immense frontier of France does not appear to have exceeded 250,000 men; besides the troops in the garrisons, most of which were national guards;—of this force about 150,000 men were in the Netherlands; and the remainder were principally under Rapp near Strasburg, and under Suchet, on the borders of Switzerland and Italy. Of the allies, none were yet come up, except the English, Germans, Dutch, and Belgians under the Duke of Wellington, who might amount to 80,000 men; and the Prussians under Blücher, who probably exceeded 100,000: the former occupied the frontier from the sea to Brussels; the latter from Brussels westward. Next to them the Bavarians and Russians were to take their position, while the Austrians, a large portion of whom were engaged at present in hostilities against Murat in Italy, and the troops of the King of Sardinia, &c. were to invade France on the south-eastern frontier. Louis had been invited to join the confederacy with what troops he might have with him, but though a great number of officers left France and joined him at Ghent, scarcely any of the French soldiers flocked to his standard. On Sunday the 11th of June, Bonaparte received addresses from the two Chambers in reply to his opening speech; and on the next day, at four in the morning, he left Paris, having nominated Generals Sebastiani, Grenier, Beaufont, &c. to the command of the capital, which had been rendered as strong as its position and nature would allow. On the 14th, he arrived at Avesnes, where he issued an order of the day, re-
minding his troops that the 14th was the anniversary of the battles of Marengo and Friedland, and that "to every Frenchman who had a heart, the moment was arrived to conquer or perish." The position of his army was as follows: The Imperial head quarters at Beaumont; the 1st corps commanded by General D'Erlon, at Solfe on the Sambre; the 2d corps commanded by General Reille, was at Ham-sur-Heure; the 3d corps commanded by General Vandammé, was on the right of Beaumont; and the 4th corps commanded by General Girard, was at Philippeville. The Prussian posts were established on the Sambre; these he attacked at day light on the morning of the 15th, and in the course of the day drove them from the river, and made himself master of the ground from Thuin to Fleurus, a distance of about 10 miles, on the Namur road; whilst on the Brussels road, he forced back a Belgian brigade to Quatre Bras, about 12 miles from the Sambre. Bonaparte in this affair evidently had the advantage, and seems to have surprised the allies.

On the 16th, the Prussian army was posted on the heights between Bril, and Sombreffe, occupying the villages of St Amand and Ligny, situated in its front. It consisted of only three corps; the 4th corps was not yet come up. Against these Bonaparte advanced in person with the 1st, 3d, and 4th corps about three o'clock in the afternoon; while Ney, whom he had at length called to the army, was ordered to put himself at the head of the 2d corps, and attack General Picton's division, the corps of the Duke of Brunswick, and the Nassau contingent, which the Duke of Wellington had dispatched in support of the Prussians, and which had reached Quatre Bras about half past two o'clock.

The first object of Bonaparte was to gain possession of St Amand; and he succeeded after a vigorous resistance. He next advanced against Ligny, where the combat was of a most desperate and sanguinary description. The Prussians, with their gallant commander, were urged on to use their most strenuous efforts, by every feeling of a national or individual nature, which can goad men to bravery and vengeance; for five hours the battle raged near this village with doubtful success, while the Prussians by retaking a part of the village of St Amand, regained an advantageous position near that village. Still, however, the French were gradually overpowering the Prussians by their superiority of numbers; anxiously did Blücher look for the arrival of the 4th corps, or the support of the English, but the former did not come up, and the latter with difficulty maintained their position at Quatre Bras. Bonaparte perceiving the advantage which he had gained, and the extreme importance of pushing it to its utmost extent, as soon as the darkness of the night favoured him, ordered a division of the infantry to make a circuit round the village: they accomplished this unobserved; while, at the same time, some regiments of cuirassiers forcing a passage on the other side, the main body of the Prussian army was taken in the rear; at the same moment, the French cavalry succeeded in repulsing several attacks of the Prussian cavalry: this completed the success of Bonaparte; the Prussians were compelled to retreat first to Sombreffe; and as the 4th corps was not yet come up, afterwards to Wavre. The attack made by Ney on the English at Quatre Bras was equally desperate in its nature, but not so successful to the French in its result; for all their charges were repulsed in the steepest manner. In this affair the Duke of Brunswick was slain.

In consequence of the retreat of the Prussians, the Duke of Wellington retired on Waterloo. The position which he occupied was good, but towards the centre it had various weak points. It ran from the Brussels road to the right about a mile and a half in length; and then turned very sharply to the right, and crossed the road from Nivelles to Namur: these two roads cross each other, so that the British position formed nearly a quarter circle. At the turn of the bottom of a slope, was a farm and orchards, called Mount St John, which was the key of the position, and the front of the centre. On their left, the British communicated with the Prussians at Wavre, through Ohain.

At half past 10 o'clock in the forenoon of the 18th, Bonaparte began to put his troops in motion; and, Waterloo, about an hour afterwards, one of his corps attacked the country-house on the right of the British, where the Nassau troops were posted: these were obliged to give way; but the house itself was so well defended, that the French could not gain possession of it. This attack on the right of the British centre, Bonaparte accompanied with a dreadful fire of artillery; under the cover of which, he made repeated attacks of cavalry and infantry, sometimes mixed, and sometimes separate, from the centre to the right: but the skill of the Duke of Wellington, and the admirable moral courage and physical strength of his troops, were unconquerable. Against one of these attacks of the French cavalry, General Picton, who was with his division on the road from Brussels to Charleroi, advanced with the bayonet. The French, struck with astonishment at the circumstance of infantry advancing to the charge of cavalry, fired, and then fled. At this moment, General Picton was unfortunately killed. The English lifeguards next advanced against the 40th and 105th regiments of French infantry: to their support the cuirassiers came up; the most sanguinary cavalry fight perhaps ever witnessed, was the consequence; but the British were victorious, and the cuirassiers were annihilated.

The battle had now lasted upwards of five hours; during which Bonaparte had lost an immense number of men, by his desperate charges, without being able to make any decisive impression. The Duke of Wellington, with the skill of a consummate general, kept his troops entirely on the defensive; but though he had reduced their strength as much as possible, yet they were beginning to be exhausted, and their brave commander frequently turned his anxious and vigilant eye to that quarter where he expected the Prussians to arrive.

At break of day, the Prussian army had begun to move; the 2d and 4th corps marched to take up a position whence they might attack the French on the rear, if circumstances proved favourable. The 1st corps was to operate on the right flank of the French; and the 3d corps was to follow slowly in order. About 5 o'clock, Bonaparte perceived the advance of part of the Prussian army, which at first he seems to have supposed to have been the division of his own army under Marshal Grouchy, who had been posted on the rear of the allies to take advantage of their anticipated defeat. As soon, however, as he ascertained that it was the Prussians, he repeated his attacks with cavalry and infantry, supported by artillery, in a more desperate and murderous manner than ever; but the British were immovable. At last, about seven in the evening, he made a last effort, putting himself at the head of his guards. He succeeded for a moment in driving back the Brunswickers; but the Duke of Wellington, putting himself at their head, and animating them by a short speech, restored the combat. At this critical moment, the Prussians came up: General Bulow advanced rapidly on the rear of the right wing of the French; and Marshal Blücher had joined in person with a corps of his army to the left of the British army, by Ohain. The Duke
FRANCE.

A.D. 1815.

The entry of Louis, 8th July.

History.

of Wellington headed the foot-guards; spoke a few words to them, which were replied to by a general hurrah; and his Grace guiding them on with his hat, they marched at the point of the bayonet, to close action with the imperial guard: but the latter began a retreat, in which they were imitated by the whole French army. The British, completely exhausted, left the pursuit to the Prussians, who, coming fresh to battle, soon changed the retreat of the French into a rout, the most destructive, perhaps, ever known. In this battle, nearly 300 pieces of cannon were taken, and upwards of 14,000 prisoners. The loss of the French in killed, especially on the 16th, when the Prussians neither gave nor received quarter, was immense; on the 16th and 18th, it could not have amounted to less than 40,000 men. On the 16th, the Prussians lost about 10,000 men, but on that 8th, the Duke of Wellington’s army about 15,000.

No battle, perhaps, ever was fought of a more osti- nate description, or more decisive in its consequences. In this one battle of Waterloo, the fate of Bonaparte was sealed, and his empire again overthrown. In this one battle, the fame of the Duke of Wellington was raised to a summit it could not possibly surpass; and the British soldiers proved that they were worthy of being commanded by such a general.

On leaving the field of battle, Bonaparte fled as rapidly as possible to Paris, where he arrived on the 21st, and convoked a council of ministers. On the 22d, the two chambers declared their sitting permanent; and Bonaparte was given to understand that his abdication was expected. He accordingly issued a declaration, in which he declared his political life terminated; and proclaimed his son, under the title of Napoleon II. His abdication was accepted by the Chambers; but the question was evaded with regard to the title of young Napoleon. A commission of five was chosen to exercise provisionally the functions of government: the members were, Fouche, Carnot, Grenier, Caulaincourt, and Quinet. At first, the Chambers seem to have entertained some hopes that the progress of the allies might have been arrested; but on the representation of Ney, that it was impossible to collect 25,000 men, they voted that an attempt should be made to negotiate an armistice with the Duke of Wellington. 

In the mean time, the Duke and Prince Blucher were advancing rapidly towards Paris. The latter was unsuccessfully opposed by Marshal Grouchy, who having united some of the fugitives from the battle of Waterloo with his corps, at last reached the capital with about 40,000 men. With these, and some of the national guards, &c., an attempt was made to prevent the Prussians from taking a position on the left of the Seine, the only part wherein defensive works had been thrown up. On the failure of this attempt, and the refusal of the Duke of Wellington to negotiate an armistice, Paris was surrendered to the allies by a military convention, the principal stipulations of which were, that the French army should march out of it, and take up a position behind the Loire; that the duty of the city should continue to be performed by the national guards; that public and private property should be respected; that no person should be called to account for his conduct or opinions; and that the convention should be common to all the allied powers, provided it were ratified by the powers on whom the armies were dependant. On the 8th of July, Louis entered his capital again, the provisional government and the chambers being previously dissolved. A few days afterwards he appointed his ministers, introducing a new regulation, according to which there is to be a privy council, comprehending the princes, the ministers, and such others as the king may name; and a council of responsible ministers. The latter are in number eight: consisting of Talleyrand, president of the council, and secretary for foreign affairs; Baron Louis, minister of finance; Fouche, Duke of Otranto, of the police; Baron Pasquier, the department of justice, and keeper of the seals; Marshal Gouvion St Cyr, the department of war; Count de Jaucour, the marine; and the Duke de Richelieu, the household. The appointment of Fouche, a man more deeply stained with the crimes of the Revolution, than perhaps any of the principal surviving actors in that dreadful drama, excited universal astonishment and indignation; but these feelings were almost entirely drawn aside from this appointment, by the state of France at the moment we are writing. The army, which evacuated Paris, for some time assumed an attitude of bold defiance on the banks of the Loire; and at length sent in a haughty, reluctant, and suspicious submission to Louis, communicated in an address from Davoust, who commanded it, more like the state paper of an independent sovereign, than the penitent submission of a rebellious and defeated general. Even after Louis had re-asceded the throne, the armies of Bavaria, Russia, and Austria, were obliged to fight their way to Paris; and in those instances, where they entered into negotiations with Bonaparte’s generals, the latter were left in a condition of independence on their legitimate sovereign, and almost placed on a level with the victorious allies. Notwithstanding the presence of nearly 300,000 troops of the allies, seditious cries and movements constantly agitate the very palace of Louis. In many of the provinces, a spirit of dissatisfaction shews itself openly. In short, to judge from the present state of France, we should conclude, that it was not the conquered but the victorious country, and that Bonaparte, instead of being an exile, was still on the throne. In this alarming crisis, the measures of Louis are timid and vacillating. A few of Bonaparte’s creatures, who swore allegiance to Louis, and then betrayed him, have been ordered to be arrested and tried; but it is extremely doubtful, whether this order will be followed even by an attempt to take them; and if they are taken, by whom are they to be tried? by men as guilty as themselves? The paramount feeling which thus agitates France, is that of wounded self-love; the disgrace and humiliation of being conquered, which, in the time of their success, they most insolently poured on other nations, is returned on themselves; the demoralization which the national character has suffered during the Revolution, has become so deeply seated, and so constitutional, that the severe remedies which have been applied serve only to irritate and inflame. Hence there is reason to apprehend, that it will require a considerable length of time, and measures of consummate wisdom applied with extreme caution, to restore France to that state, in which she may become a peaceful, safe, and useful member of the community of Europe.

Although the fate of Bonaparte, after his second abdication, is rather the subject of biography than of history, yet we shall here subjoin the particulars of it. Before the allies reached Paris, he quitted that capital and went to Rochefort, where vessels were prepared to carry him and his attendants to America. The British government, however, informed of his plan, blockaded this part of the French coast so effectually, that he found himself compelled to surrender to Captain Maitland of the Bellorphon, who commanded the blockading squadron. In this ship he was brought to the coast of England, but not suffered to land; and about the middle of August, he was sent to the island of St. Helena with part of his suite, to be kept there during the remainder of his life.
FRANCE.

STATISTICS.

CHAP. I.

Boundaries and Extent of France—Progressive Geography—Division into Provinces and Departments—Military Divisions.

By the treaty of Paris in 1814, the kingdom of France was reduced within the same limits that bounded it previously to the Revolution; but its extent of territory was rather larger; for Avignon and the county of the Venetian, which had formerly belonged to the Pope, but which had been incorporated with France before January 1792, were declared to be integral and permanent parts of that kingdom by the treaty alluded to.

France, as it is bounded at present, is marked out, as one of the separate kingdoms of Europe, by natural limits on three of its sides. These are, the Channel between it and England on the north; the Bay of Biscay on the west; the Pyrenean mountains and the Mediterranean sea on the south; on the east, north-east, and south-east, its limits are not accurately fixed by nature. On the east, it borders on Germany and Switzerland; on the north-east, on those provinces which formerly composed the Austrian Netherlands, but which are now united to Holland; and on the south-east, on Savoy and Piedmont. It extends from the 42$^\circ$ to nearly the 51st degree of north latitude, and comprehends above 11 degrees of longitude; the most easterly part of Alsace lying 7 degrees eastward of the meridian of Greenwich, and the most westerly part of Brittany rather more than 4 degrees westward of the same meridian. Were it not for this province, which stretches about 100 miles farther into the Atlantic Ocean than any other part of the kingdom, the form of France would be almost a square, and the breadth and length pretty nearly equal, i.e. about 580 miles.

The area of France has been variously estimated. According to the map of the Royal Academy of Sciences at Paris, it contains 29,886 square leagues, 25 to a degree; according to the map of Delisle, 25,889. Nolin makes it 28,054; Defer, 31,278; Sanson, 31,657: the medium of these is 28,642. Buschung, reckoning 15 miles to a degree, fixes the extent of France at 10,000 square miles; the Marshal de Vauban makes it 30,000 leagues, or 140,940,000 arpents; Voltaire 130,000,000 arpents. Templeman gives it an extent of 138,887 square geographical miles; but as he reckons only 60 miles to a degree, this number must be reduced to 119,243,874 acres. Pencil, by covering his map with shot to every indenture of outline, found the kingdom to contain 103,021,510 arpents, each of 100 perches, at 22 feet the perch, or 134$\frac{1}{2}$ toises square to the arpent; instead of which, the arpent of Paris contains but 900 toises. According to this measurement, France contains 81,877,016 English acres; but this is undoubtedly too few. The Encyclopédie assigns 100,000,000 arpents; observing that, by the map of Cassini, the amount is 125,000,000. The author of Le Fort Aboune calculates it at 105,000,000; and the author of Apologie sur l'Est de Nantes, at 135,000,000. M. Necker seems to have been the first who ascertained the area of France with considerable accuracy. According to him (not including Corsica) it comprehend 26,951 leagues square, or 22,812 toises, or 156,024,213 arpents of Paris, which is equivalent to 131,782,905 English acres. This calculation is nearly adopted by M. Jorje, author of the Credite Nationale, who reckons that France contains 27,000 leagues at 2282 toises, 5785 arpents of Paris to a league, and also by Mr A. Young: This gives to France 156,225,720 arpents. The committee of the first National Assembly stated it soon afterwards at 26,463 square leagues; and this is probably pretty accurately the area of France as it is now bounded.

The progressive geography of this kingdom presents very different limits and divisions at different times. The ancient Gaul, as has already been remarked in the History of France, comprehended a larger portion of territory than France now contains. Under the name Gallia, was originally comprehended Gallia Cisalpina, and Gallia Transalpina: the former was entirely on the south side of the Alps, and the latter contained all the present France, and that part of Germany and Belgium westward of the Rhine. According to the Abbe du Fresnoy, ancient Gaul, by which he means Gallia Transalpina, was bounded on the south by the Pyrenees, the Mediterranean Sea, and the Var; on the east by the Alps and the Rhine; on the north by the same river; and on the west by the ocean. The Romans first illustrated the geography of Gaul, which they considered as divided into three chief regions, the Celtic, Belge, and Aquitaine. The bounds of Gallia Celtica were the ocean, the Seine, the Marne, the Saone, the Rhine, and the Garonne. Gallia Belgica was bounded by the ocean, the Seine, the Marne, the mountains of Vosges, the Rhine, and the ocean; and Gallia Aquitania by the ocean, Garonne, and the Pyrenees. Augustus divided Gaul into four parts; Gallia Narbonensis, which comprehended Languedoc, Poix, Vivarres, Provence, Dauphiny, and Savoy; Aquitania, which was of larger extent than it had been in the time of Julius Caesar, and comprehended all the country between the Pyrenees, the ocean, and the Loire; Lugdunensis, the largest of all, which was bounded by the ocean, the Loire, the Seine, the Marne, the mountains of Vosges; and Belgica, which was bounded by the ocean, the country of Caux, the Seine, the Marne, the mountains of Vosges, and the Rhine.

The Notitia Imperii, which was made in the fourth century, presents us with another division of Gaul; for there it is divided into five great provinces; Lugdunensis, Belgica, Germanic, Viennensis, and Aquitania, each of which are subdivided into several others. The Emperor Constantine the Great divided Gaul into fifteen provinces or governments, six of which were consular, and eleven under certain presidents sent by the Emperor, who resided in the capital cities. The names of the provinces and the capital cities were, 1. Narbonensis prima, capital city Narbonne; 2. Narbonensis secunda, capital city Aix in Provence; 3. Viennensis, capital city Vienne in Dauphiny; 4. Alpes Graiae and Pernes, capital city Moutenon in Tarraite, a province of Savoy; 5. Alpes Maritimes, capital city Embrun in Dauphiny; 6. Lugdunensis prima, capital city Lyons; 7. Lugdunensis secunda, capital city Rouen; 8. Lugdunensis tercia, capital city Tours; 9. Lugdunensis quartae, capital city Sens in Champagne; 10. Sequania, capital city Besançon; 11. Aquitania prima, capital city Bordeaux; 12. Aquitania secunda, capital city Bourdeaux; 13. Novempopularia, capital city Aich in Gascony; 14. Germania prima, capital city Mentz; 15. Germania secunda, capital city Co-

Vol. IX. Part II.
France.

After the death of Clovis, the dominion of the Franks was divided into two parts, viz. Oesterric, or the Eastern Kingdom, called by corruption Austrasia; and Westerric, or the Western Kingdom, called Neustria. The former contained all old France, as it existed in the time of Clovis; that is, all the country that reached from the Rhine to the Loire, and the country behind the Marne, which the Franks had conquered, together with Rheims, Chalons, Cambry, and Laon, which was from that time a separate kingdom, the seat of which was Metz in Lorraine. Aquitania was not comprised under the name of France; nor Burgundy, either. that had been ceded to the lower part of Brittainy Armorica, which was at this time an independent state. Neustria contained all the country that lies between the Loire and the Meuse, and was divided into three kingdoms: 1. France, the capital of which was Paris; this comprehended what is now called the Isle of France; 2. Orleans; 3. Soissons. Afterwards, when the Franks had subdued the Visigoths and Burgundians, two other kingdoms were erected, Aquitaine and Burgundy.

Some French historians and geographers are of opinion, that under the Merovingian race of kings, the territory of France had nearly the same limits which it now possesses; that under the Carlovingian race nearly the whole was wrested from the sovereign by the abuse of the feudal system; and that, under the Capetian dynasty, nearly the whole was recovered. The original domain of the crown under Hugh Capet seems to have consisted of Picardy, the Isle of France, and the Orleans. Berry was the first province that was reunited to the crown: It was governed by Counts, who continued in possession of it till about the year 1100, when Eudes Aspin sold it to King Philip I. who united it to his dominions. Touraine and Normandy were consecrated to the crown, or conquered under Philip Augustus. Languedoc was next annexed, by inheritance, under Philip the Hardy; but, according to some, it cannot be considered as the crown till the reign of King John in 1316. Champagne was governed by its Counts till 1274, at which period, Jane, who was the last Countess, was married to Prince Philip, son of Philip the Hardy; and thus this province was united to France, though the final and permanent union did not take place till 1361, in the reign of King John. The province of Lymnois came into the possession of the crown under Philip the Fair; Dauphiny under Philip de Valois. Poitou, Annis, Limosin, and Saintonge, were conquered by Charles V., and Guiennc and Gascony by Charles VII. Maine and Anjou were acquired by inheritance, under Louis XI. The same monarch seized the duchy of Burgundy as an escheat to the crown, and took possession of all Provence on the death of Charles, King of Sicily, who was Count of Provence. Anne of Brittany, the only daughter of Francis II. the last duke of that province, married Charles VIII. and afterwards Louis XII. by the last of whom she had two daughters, the eldest of whom married Francis I. who united Brittany to the crown of France in 1532. Under this monarch, Auvergne, Bourbonnois, and Marche, were consecrated and united to the crown. Bearn, Foix, and a part of Gascony, were the patrimony of Henry IV. and thus were united to France when he ascended the throne of that kingdom. Ronsillon formerly belonged to Spain; but Louis XII. took it in 1542, and it was afterwards yielded to France by the treaty of the Pyrenees in 1659. The house of Austria had Artois till the reign of the same monarch; but having conquered great part of it, it was ceded to him by Philip IV. King of Spain, and afterwards by Charles II. his son. Alsace was yielded to the French by the treaty of Ryswick, in the reign of Louis XIV. Franche Compté continued subject to the house of Austria till Louis XIV. seized it in 1668, but he was obliged to restore it the next year; He seized it again in 1674, and it was confirmed to him by the treaties of Nimqueen and Ryswick. That part of the Low Countries which France retains by the recent treaty of Paris, were acquired by conquest in the reign of Louis XIV. Lorraine was the last acquisition of France before the Revolution, though part of it, the three bishoprics of Metz, Toul, and Verdun, were seized by Henry II. and yielded to France by the treaty of Westphalia in 1648: the other parts of this province, the duchy of Lorraine properly so called, and the duchy of Bar, were seized by Louis XV. and afterwards ceded to him by treaty.

Before the Revolution, France was divided into 92 distinct governments, 18 of which are in the circuit, and 14 in the middle of the kingdom. The first national assembly, by its decrees of the 15th of January, and the 16th and 26th of February 1790, divided France into 83 departments. As, however, the divisions as they existed before the Revolution are still frequently referred to, and as a knowledge of them is absolutely necessary to the right understanding of the history of this kingdom, we shall enumerate them as well as the corresponding departments. It is proper, however, to premise that each department is subdivided into 3, 4, or 5 districts, called communes arrondissements. These districts are again divided into cantons, and, lastly, each canton is composed of a certain number of communes, that is to say, of towns and villages. A commune is sometimes a single town, and sometimes a union of several villages, possessing a mayor and communal munipacity. All the considerable cities are divided into several communes.

1. The province of Flanders, or the territories which Flanders, France possessed in the western part of the Netherlands before the Revolution, and which she still retains. This forms the department of the Nederlands, which contains 6 districts, 60 cantons, and 671 communes; its territorial extent is 6930 kilometers,—24 kilometers being very nearly equal to 7 square miles, of 60 to a degree. The principal town in this department is Douai.

2. The province of Artois forms the department of Artois for the Straits of Calais, which contains 6 districts, 43 cantons, and 953 communes; its territorial extent is 7014 kilometers; its principal town is Arras.

3. The principal part of Picardy forms the department of the Somme, which contains 5 districts, 41 cantons, and 848 communes; its territorial extent is 6514 kilometers; its principal town is Amiens.

4. Normandy is divided into the departments of the Lower Seine, the Eure, the Orne, Calvados, and the Channel. The Lower Seine contains 3 districts, 20 cantons, and 79 communes; its territorial extent is 6372 kilometers; its principal town is Rouen. The department of the Eure contains 5 districts, 66 cantons, and 843 communes; its territorial extent is 6154 kilometers; its principal town is Evreux. The department of the Orne contains 4 districts, 33 cantons, and 627 communes; its territorial extent is 6375 kilometers; its principal town is Alençon. The department of Calvados contains 6 districts, 37 cantons, and 856 communes; its territorial extent is 6440 kilometers; its principal town is Caen. The department of the Cha-
The province of the Isle of France is divided into the departments of the Aisne, Oise, Seine, and Seine-Marne. The department of the Aisne contains 5 districts, 37 cantons, and 835 communes; its territorial extent is 7422 square kilometers; its principal town is Laon. The department of the Oise contains 4 districts, 35 cantons, and 738 communes; its territorial extent is 6082 square kilometers; its principal town is Beauvais. The department of Seine contains 3 districts, 20 cantons, and 79 communes; its territorial extent is 453 square kilometers; its principal town is Paris. The department of Seine-Marne contains 5 districts, 29 cantons, and 561 communes; its territorial extent is 4127 square kilometers; its principal town is Melun. The department of the Seine and Oise contains 5 districts, 36 cantons, and 696 communes; its territorial extent is 5880 square kilometers; its principal town is Versailles.

The province of Champagne contains the departments of Ardenne, Meuse, Marne, Nievre, Oise, Oise, and Seine-et-Marne. The department of Ardenne contains 5 districts, 34 cantons, and 599 communes; its territorial extent is 6342 square kilometers; its principal town is Mezières. The department of the Marne contains 5 districts, 32 cantons, and 699 communes; its territorial extent is 8486 square kilometers; its principal town is Châlons. The department of the higher Marne contains 3 districts, 28 cantons, and 582 communes; its territorial extent is 6540 square kilometers; its principal town is Chaumont. The department of the Aube contains 5 districts, 26 cantons, and 428 communes; its territorial extent is 6212 square kilometers; its principal town is Troyes. The department of the Yonne contains 5 districts, 24 cantons, and 484 communes; its territorial extent is 7740 square kilometers; its principal town is Auxerre.

The province of Lorraine is divided into the departments of Meuse, Moselle, Meurthe-et-Moselle, and Vosges. The department of the Meuse contains 4 districts, 28 cantons, and 591 communes; its territorial extent is 6275 square kilometers; its principal town is Bar-le-Duc. The department of Moselle contains 4 districts, 30 cantons, and 934 communes; its territorial extent is 6551 square kilometers; its principal town is Metz. The department of Meurthe-et-Moselle contains 5 districts, 29 cantons, and 718 communes; its territorial extent is 6490 square kilometers; its principal town is Nancy. The department of Vosges contains 5 districts, 30 cantons, and 550 communes; its territorial extent is 6822 square kilometers; its principal town is Epinal.

The province of Alsace is divided into the departments of the Lower and Higher Rhine. The department of the Higher Rhine contains 5 districts, 39 cantons, and 703 communes; its territorial extent is 6030 square kilometers; its principal town is Colmar. The department of the Lower Rhine contains 4 districts, 37 cantons, and 616 communes; its territorial extent is 5095 square kilometers; its principal town is Strasbourg.

The province of Brittany comprehends the departments of the Ille-et-Vilaine, Lower Loire, Morbihan, the North Coast, and Finistere. The department of the Ille-et-Vilaine contains 6 districts, 43 cantons, and 359 communes; its territorial extent is 7185 square kilometers; its principal town is Rennes. The department of the Lower Loire contains 5 districts, 45 cantons, and 209 communes; its territorial extent is 7660 square kilometers; its principal town is Nantes. The department of Morbihan contains 4 districts, 37 cantons, and 283 communes; its territorial extent is 7067 square kilometers; its principal town is Vannes. The department of the North Coast contains 5 districts, 47 cantons, and 376 communes; its territorial extent is 7567 square kilometers; its principal town is Saint-Brieuc. The department of Finistere contains 5 districts, 43 cantons, and 287 communes; its territorial extent is 7292 square kilometers; its principal town is Quimper.

The province of Maine is divided into the departments of the Maine and Sarthe. The department of the Maine contains 3 districts, 27 cantons, and 285 communes; its territorial extent is 4542 square kilometers; its principal town is Laval. The department of the Sarthe contains 4 districts, 33 cantons, and 413 communes; its territorial extent is 6474 square kilometers; its principal town is Le Mans.

The province of Anjou comprises the department of the Maine and Loire, which contains 5 districts, 34 cantons, and 385 communes; its territorial extent is 7671 square kilometers; its principal town is Angers.

The province of Touraine comprises the departments of Indre and Loire, which contains 3 districts, 24 cantons, and 311 communes; its territorial extent is 4623 square kilometers; its principal town is Tours.

The province of Orléanais comprises the departments of Eure and Loire, Loiret, Cher, and the Loiret. The department of the Eure and Loire contains 5 districts, 36 cantons, and 343 communes; its territorial extent is 6184 square kilometers; its principal town is Chartres. The department of the Loiret contains 4 districts, 24 cantons, and 309 communes; its territorial extent is 6714 square kilometers; its principal town is Blois. The department of the Loire contains 4 districts, 31 cantons, and 365 communes; its territorial extent is 7047 square kilometers; its principal town is Orleans.

The province of Poitou comprehends the department of Vienne, the two Sèvres, and La Vendée. The department of Vienne contains 5 districts, 31 cantons, and 344 communes; its territorial extent is 7494 square kilometers; its principal town is Poitiers. The department of the Two Sèvres contains 4 districts, 31 cantons, and 365 communes; its territorial extent is 6837 square kilometers; its principal town is Niort. The department of La Vendée contains 3 districts, 29 cantons, and 324 communes; its territorial extent is 7242 square kilometers; its principal town is Fontenay.

The province of Berry comprehends the departments of the Indre and the Cher. The department of the Indre contains 4 districts, 38 cantons, and 275 communes; its territorial extent is 7385 square kilometers; its chief town is Châteauroux. The department of the Cher contains 3 districts, 29 cantons, and 307 communes; its territorial extent is 7385 square kilometers; its principal town is Bourges.

The province of Nivernais comprises the department of the Nivernais. Nievre, which contains 4 districts, 25 cantons, and 330 communes; its territorial extent is 7565 square kilometers; its principal town is Nevers.

The province of Bourbonnais comprises the department of Bourbonnais, Allier, which contains 4 districts, 26 cantons, and 330 communes; its territorial extent is 7425 square kilometers; its principal town is Moulins.

The province of Burgundy comprises the department of the Côte d’Or, Saône-et-Loire, and the Ain. The department of the Côte d’Or contains 4 districts, 36 cantons, and 733 communes; its territorial extent is 7885 square kilometers; its principal town is Dijon.
FRANCE.

The department of the Saone and Loire contains 5 districts, 48 cantons, and 609 communes; its territorial extent is 8912\,\text{km}^2; its principal town, Macon. The department of the Ain contains 4 districts, 92 cantons, and 416 communes; its territorial extent is 6675 kilometers; its principal town is Bourg.

Districts.

The province of Franche Comté comprehends the districts of the Higher Saone, the Doubs, and Jura. The department of the Higher Saone contains 5 districts, 48 cantons, and 644 communes; its territorial extent is 5582\,\text{km}^2; its principal town is Vesoul. The department of the Doubs contains 4 districts, 25 cantons, and 605 communes; its territorial extent is 5340 kilometers; its principal town is Besançon. The department of Jura contains 4 districts, 32 cantons, and 728 communes; its territorial extent is 5274\,\text{km}^2; its principal town is Lons-le-Saulnier.

XX. The Pays d’Auvergne.

The department of the Lower Charente, which contains 6 districts, 37 cantons, and 506 communes; its territorial extent is 7247\,\text{km}^2; its principal town is Saintes.

XXI. The province of Saintonge.

The province of Saintonge forms the department of the Charente, which contains 5 districts, 25 cantons, and 455 communes; its territorial extent is 6310 kilometers; its principal town is Angouleme.

XXII. The province of Marche.

The province of Marche comprehends the departments of the Higher Vienne, and the Creuse. The department of the Higher Vienne contains 4 districts, 26 cantons, and 224 communes; its territorial extent is 6002\,\text{km}^2; its principal town is Limoges. The department of the Creuse contains 4 districts, 25 cantons, and 296 communes; its territorial extent is 5902\,\text{km}^2; its principal town is Gueret.

XXIII. The Limosin forms the department of Corrèze, which contains 3 districts, 29 cantons, and 294 communes; its territorial extent is 5857\,\text{km}^2; its principal town is Tulle.

XXIV. The province of Auvergne comprehends the departments of Puy de Dome and Cantal. The department of Puy de Dome contains 3 districts, 50 cantons, and 458 communes; its territorial extent is 8450 kilometers; its principal town, Clermont. The department of Cantal contains 4 districts, 23 cantons, and 270 communes; its territorial extent is 6937 kilometers; its principal town is Aurillac.

XXV. The province of Lyonnais.

The province of Lyonnais is divided into the departments of the Rhone, and the Loire. The department of the Rhone contains 2 districts, 25 cantons, and 262 communes; its territorial extent is 2935 kilometers; its principal town is Lyons. The department of the Loire contains 3 districts, 28 cantons, and 327 communes; its territorial extent is 5135 kilometers; its principal town is Montbrison.

XXVI. The province of Guienne.

The province of Guienne is divided into the departments of the Gironde, the Dordogne, the Lot and Garonne, the Lot, Aveyron, the Gers, the Higher Pyrenees, and the Landes. The department of the Gironde contains 6 districts, 48 cantons, and 580 communes; its territorial extent is 1170 kilometers; its principal town is Bordeaux. The department of the Dordogne contains 5 districts, 47 cantons, and 642 communes; its territorial extent is 9482\,\text{km}^2; its principal town is Perigueux. The department of the Lot and Garonne contains 4 districts, 38 cantons, and 463 communes; its territorial extent is 6100 kilometers; its principal town is Agen. The department of the Lot contains 4 districts, 41 cantons, and 440 communes; its territorial extent is 7432\,\text{km}^2; its principal town is Cahors. The department of Aveyron contains 5 districts, 43 cantons, and 589 communes; its territorial extent is 9477\,\text{km}^2; its principal town is Rodez. The department of Gers contains 5 districts, 30 cantons, and 700 communes; its territorial extent is 7047\,\text{km}^2; its principal town is Auch. The department of the Higher Pyrenees contains 3 districts, 26 cantons, and 501 communes; its territorial extent is 4857\,\text{km}^2; its principal town is Tarbes. The department of the Landes contains 3 districts, 28 cantons, and 658 communes; its territorial extent is 9475 kilometers; its principal town is Mont-de-Marsan.

XXVII. The province of Bearn forms the department of the Lower Pyrenees, which contains 5 districts, 40 cantons, and 650 communes; its territorial extent is 6072\,\text{km}^2; its principal town is Pau.

XXVIII. The province of Foix forms the department of the Arriege, which contains 3 districts, 20 cantons, and 337 communes; its territorial extent is 5050 kilometers; its principal town is Foix.

XXIX. The province of Roussillon forms the department of the Eastern Pyrenees, which contains 3 districts, 17 cantons, and 249 communes; its territorial extent is 337\,\text{km}^2; its principal town is Perpignan.

XXX. The province of Languedoc is divided into the departments of the Tarn, the Higher Garonne, the Herault, the Aude, the Gard, the Ardèche, the Higher Loire, and the Lozère. The department of the Tarn contains 4 districts, 35 cantons, and 536 communes; its territorial extent is 6080 kilometers; its principal town is Castres. The department of the Higher Garonne contains 5 districts, 42 cantons, and 691 communes; its territorial extent is 6077\,\text{km}^2; its principal town is Toulouse. The department of the Herault contains 4 districts, 36 cantons, and 333 communes; its territorial extent is 6512\,\text{km}^2; its principal town is Montpellier. The department of the Aude contains 4 districts, 31 cantons, and 486 communes; its territorial extent is 6542\,\text{km}^2; its principal town is Carcassonne. The department of the Gard contains 4 districts, 38 cantons, 365 communes; its territorial extent is 6280 kilometers; its principal town is Nîmes. The department of the Ardèche contains 3 districts, 31 cantons, and 335 communes; its territorial extent is 5710 kilometers; its principal town is Privas. The department of the Higher Loire contains 3 districts, 25 cantons, and 272 communes; its territorial extent is 5282\,\text{km}^2; its principal town is Le Puy. The department of the Lozère contains 3 districts, 24 cantons, and 193 communes; its territorial extent is 5390 kilometers; its principal town is Mende.
CHAPTER II.

Face of the Country—Mountains—Rivers—Etangs—Sea Coast—Canals—Soil—Climate.

The face of the country in France is generally level; elevations, deserving the name of mountains, occurring about the centre, and in the southern provinces; and Mr Young remarks, that it is 400 miles south of Calais before we meet with the mountains of Auvergne, which are connected with those of Dauphiny, Languedoc, and Provence, but not with the Pyrenees. These, and the other mountains, we shall afterwards particularly notice; at present we shall confine ourselves to the other features of the country. The finest parts of France lie along the course of the Seine to Paris; thence by the great road to Moulins, at which place it should be left, and the road to Auvergne followed; and from hence to Viviers on the Rhine, and so by Aix to Italy. The provinces of Bretagne, Maine, and Angouleme, have, in general, the appearance of deserts: the first has been compared to the west of Devonshire; it comes, however, nearer to Cornwall. Some parts of Touraine are rich and pleasing, but most of the province is deficient in beauty. Picardy is uninteresting, and has been called the Cambridgeshire of France. Poitou is by no means a pleasant province, and its marshes resemble the Norfolk and Lincolnshire fens. Champagne is little less interesting, in general, than Poitou. Where Lorraine, Franche Comté, and Burgundy, are well wooded, they are gloomy; and, even in the open parts of them, they are destitute of cheerfulness. The same character applies to the provinces of Berry and La Manche. The richness of Flanders, Artois, and Alsace, is rather that of utility than of picturesqueness. In the opinion of Mr Young, the province of Limosin possesses more general beauty than any other province of France; the Vivarais and the adjoining part of Dauphiny are the most romantic. The picturesque beauty of the hilly parts of France is much increased by the rich and luxuriant verdure of the chestnut trees, particularly in the Limosin, the Vivarais, Auvergne, and other districts where they are common.

The most level tracts are the French Netherlands on the north; on the western side, extensive morasses occur in the department of La Vendée and the adjacent districts. From the mouth of the Garonne nearly to the borders of Spain, the coast consists of a flat, sandy, and barren tract, called the Landes. The other parts of France are, in general, agreeably diversified with gentle risings and depressions.

The principal mountains are, 1. The Cevennes, which are the principal centre of the primitive mountains of France, and extend into several branches. According to Delametherie, the principal branch runs along the river Ardeche towards Alès; another branch traverses the Rhone, on the side of Tournon and Vienne, towards the plains of Dauphiny; a third branch forms the mountains of Beaujolais, passing by Autun &c. till it is lost at Avalone. This branch is about 70 leagues long, but in general very narrow, not exceeding in most places much above a league; the fourth branch separates the basin of the Loire from that of the Allier, and forms the mountains of Forez; the fifth branch separates the basin of the Allier from that of the Cher, and passes by Clermont to Montluçon; the sixth branch stretches towards Limoges; the seventh stretches from the Dordogne towards the Charent; and the eight divides the Dordogne from the Garonne. The lofty Cantal and Mount D'Or seem to be part of the Cevennes, proceeding from the main ridge in a north-westerly line. The northern part of the chain is styled the Puy de Dome; its elevation above the level of the sea is about 5000 feet; Cantal about 6200, and the Puy de Sausi, which is the highest point, about 6300. This enormous assemblage of rocks covers an extent of 120 miles, and is chiefly basaltic.

2. On the eastern border of France, the low and rounded chain of the Vosges begins, on the frontiers of Champagne and Franche Comté, and running southwards, parallel to the course of the Rhine, terminates in the Jura.

3. A chain of the Alps crosses the three departments Alps of the Maritime Alps, Lower Alps, and Upper Alps, and afterwards stretching to the north, divides France from the kingdom of Italy and Switzerland; perhaps the Vosges may also be regarded as a branch of the Alps. In the department of the Drome, another branch of the Alps takes its rise, which crosses, the departments of the Ardeche, Loire, Rhone, Saone and Loire, and Cote D'or, as far as Dijon.

4. The chain of the Pyrenees stretches on the south Pyrenees of France from the port of V Hendres, on the coast of the Mediterranean Sea, to the Atlantic Ocean on the coast of Spain. Its greatest breadth is 40 leagues; its highest summit 1751 toises above the level of the sea; the length about 212 miles. Mont Perdu is the highest elevation of the Pyrenees; Mont Canigou is the chief of the Eastern Pyrenees; the hill is of difficult ascent; it is 1440 toises above the Mediterranean; the summit of it is covered with loose fragments; the ruins apparently of a rock once higher. The high cliffs of Canigou are composed of gneiss. The Pyrenean chain appears at a distance like a shaggy ridge, presenting the segment of a circle fronting France, and descending at each extremity.
1. The Seine rises in Burgundy, not far from Dijon; it afterwards runs through Champagne, and waters Troyes, where it formerly began to be navigable; but now it does not carry boats till it comes to Mez; at Montereau it is joined by the river Yonne; afterwards it crosses the island of France, where it waters Melun, Corbeil, and Paris; before, however, it reaches the capital, it is considerably augmented by the Marne, and six leagues beyond Paris it receives the Oise. The principal place by which it flows, after it leaves Paris, is Rouen: it empties itself, by a large mouth, into the sea at Havre de Grâce. This river carries, near Paris, heavier vessels than any other river in Europe, in proportion to the length of its course and the breadth of its channel. The whole length of its course is about 250 miles. The valley of the Seine, above Rouen, is equal in point of breadth, beauty, and fertility, to most of the river valleys in Europe. In some places it has worn its channel through about 50 strata of chalk.

II. The Loire is navigable: its course is first to the south, then to the west, and then to the north: it afterwards turns to the north-west, near Semur, where it receives some small streams from Burgundy, which province it divides from the Bourbonnais: it next enters Nivernois, where it washes Nevers, and receives the Allier; thence running along the province of Berry, which it divides from Orleans, it waters the city of Orleans; here it turns to the south-west, and passing Blois, Amboise and Tours, receives the Cher, the Indre, and afterwards the Vienne. It next runs by Saumur, and shortly afterwards is augmented by the waters of the Sarthe, which comes from Angers; leaving Anjou, it enters Brittany, washes Nantes, and widens its channel, in which are several islands, it falls into the sea between Croisic and Bourgneuf. Its course is estimated at 430 miles; and it is navigable to the distance of 80 or 90 miles from its source. From Angers to Nantes it is generally considered as one of the finest rivers in the world; the breadth of the stream; the islands of woods; the boldness, culture, and richness of its banks, all combine (in the opinion of Mr. Young,) to render that part of its course eminently beautiful; but, during the rest of its course, its character changes, and it loses all its beauty. The benefits which it renders to commerce and industry are incalculable; hence it is bordered by rich and populous cities, and its banks announce fertility and abundance; but the quantity of loose sand which it carries down, renders its course uncertain and deceptive, especially from Orleans to the sea. To prevent the dangers arising from shoals, which shift with the frequent variations of the current, watermen are constantly employed in placing little branches of willows on these shoals, and in preceding large barges, which are commonly united to each other in numbers more or less considerable; a little boat always attends them, with a pilot to lay down the buoys. To confine this river to its bed, a large dyke has been constructed on both its banks, from Blois to Angers, which immense work is called les levées, or the causeways; its origin is traced back to the time of Charlemagne, and from that period care has been taken to keep it in repair. The height of these causeways is 25 feet, and their breadth 40; the middle is paved or gravelled, and the sides are protected by parapets of earth.

III. The Garonne rises in the valley of Adan, in Catalonia, between Valentine and St. Gaudens; where its course changes from the north-west to the north-east, it receives the Ger; it receives several other small streams before it comes to Toulouse, at which place it again turns to the north-west; it afterwards forms an island, and receives the Sarbel Grenada. On its junction with the Tarn, it changes its course to the west. Several other streams fall into it, but none of any considerable note, before it arrives at Bordeaux. Below this city it forms several islands, and receives the Dor-dogne, which rises in the mountains of Auvergne; after their junction, both lose their names, and are called together the Gironde. The Gironde enters the sea near the town of Cordovan, by two channels; the whole course of this river is about 250 miles. The shoals in it, between its mouth and Bordeaux, are innumerable, and of such dangerous a nature, that few ships that get on them are ever able to get off; the bottom being a soft mud, and sandy, they make a bed for themselves, and in a tide's time are swallowed up. The Garonne begins to be navigable at Toulouse; from whence to Bordeaux it carries the largest boats. The tide flows up nearly 80 leagues from the mouth of the river, and it is said that when it is flowing in, there appear two different levels on the surface; that which is towards the sea being considerably higher than that which is towards the source of the river.

IV. The great river of the south of France is the Rhone. It springs from the glacier of Furca, near the mountains of Grimsel in Switzerland. After issuing from the lake of Geneva, it takes a western course till it reaches Lyons, where it is joined by the Saone, which forces the Rhone into its own direction. Below Lyons it is joined by several rivers, the principal of which are the Isere and the Durance. Pursuing its course to the south, according to the direction which it received from the junction with the Saone, it disengages itself into the Mediterranean by two principal channels, the one on the west, the other on the east, which form a small island called Bandul. Only very small vessels can enter this river by the west channel; the other entrance is the deepest, and by this the tartars, and other vessels which go to Arles, enter the Rhone. In several places this river seems to have changed its course. It divides itself into two branches just above Avignon, which unite again a little below it, forming a pretty considerable island. It appears from many old records and charters, that the branch which at present runs without the walls of Avignon, once had its channel where is now the centre of the town; and, by the same evidence, it is proved, that several centuries ago, there was no water at the foot of the heights on which the town of Villeneuve stands, where now runs the principal branch of the Rhone; and, by examining the country on the right bank of this branch of the river, where there is a valley, it was found that the soil of this valley is very similar to that which now forms the bed of the Rhone, and that it has the same level. It is also a well-known fact, that the river had only been kept from making its way into its former channel by means of very strong dykes; and on a ridge of rocks that bor-
der part of the valley, a number of large iron rings have been found fixed, such as might be supposed to have been placed there for the purpose of fastening boats. The entire course of the Rhone is about 400 miles. From Lyons to Avignon is about 140 miles by the river, and in nearly the whole of this course the banks of the Rhone are extremely picturesque, winding almost entirely among rocks and mountains, which present perpetual pictures to the eye. Between Lyons and Vienne, the scenery is particularly delightful: the air of this climate is balmy; the mountain scenery exhilarating; the Rhone clear, rapid, and majestic; rocks, woods, vineyards; chateaux on commanding eminences; cottages embosomed in trees, retiring from the view; the busy traffic of the river, and prosperous villages on its banks. The scenery of the Garonne from Toulouse to Bordeaux, has sometimes been compared with that which the Rhone exhibits from Lyons to Avignon; but, though both striking, their features are of a very different character; those of the Rhone have been just described. The Garonne rolls through extensive plains, the luxuriant fertility of which cannot be exceeded; but there is little that is picturesque,—nothing that is sublime. The Saone, though it loses its name in the Rhone, deserves a short notice. It rises in Mount Vosges, and, as has been already mentioned, joins the Rhone at Lyons. The confluence of these two rivers is now about half a league below this city. It was formerly under its very walls; and the space which lies between the town and its present junction was an island called Mogniat. A plan has been formed, and partly executed, for enlarging the city, by filling up the bed of the river between the island and the main land. It is scarcely possible to conceive a greater contrast than what is presented by the two rivers, the Rhone and the Saone; the former runs with wonderful rapidity, owing to the great fall which it constantly has towards the sea; the latter is so extremely tranquil, that it is difficult to say which way the current sets. This character is preserved even at their very junction; and it is said, that a distinct line of demarcation may be observed between them, which slopes gradually off, till the character of the tranquil Saone is wholly lost, and that of the impetuous Rhone alone remains. Of the other tributary streams of the Rhone, we shall notice only the Isere, and the Durance. The former has its rise in the mountains of Savoy, and passes through the town of Grenoble. From its rising in a mountainous country, it is subject to violent inundations, and can only be crossed near Valence by a ferry boat of a peculiar construction. The Durance also rises in the mountain Genevre, on the borders of Savoy, and is full of banks and shoals, having no certain or fixed channel. Many plans have been formed at different times to render it navigable, but they have either to all proved abortive.

France is almost entirely destitute of lakes. There are indeed a few in Provence and Upper Languedoc, but they are of little depth, and spread over a considerable surface of ground, and by no means either pleasing or picturesque in their appearance. Some of them in Upper Languedoc have been drained, and applied advantageously to the purposes of agriculture. On the coast of these two provinces, there are, however, a great number of inlets of the sea, which the French call estangs. They have a communication with the sea through a narrow channel, by which they are supplied with their waters, which are consequently salt. From the size of some of them, it might be supposed, that they were capable of being converted into harbours; but though the waters cover a great extent of ground, they are of no depth, and incapable of being navigated, except by fishing boats. The principal estang on the coast of Languedoc, is the Etang de Thau; on the coast of Provence, the Etang de Berre. The latter is about twenty miles long and sixteen broad, and communicates with the Mediterranean Sea by a narrow channel, in which are three islands.

The Artesian wells may be noticed in this place. The name is derived from the province of Artois, where the mode appears to have been originally followed; they are now by no means uncommon in the north of France. The mode consists in boring, and then driving a wooden pipe into the cavity. Through this pipe the borer is made to act, and increase the depth. Another pipe is then driven in, so as to sink the first still lower. By a continuation of this process, the length of pipe is carried to a very great depth if necessary, and water is conducted from the lower springs to the surface.

Respecting the sea coast of France, we must content ourselves with a few desultory and unconnected notices. In thirty leagues of coast, Languedoc has not one good harbour, whereas Provence abounds in them. This seems to arise from the sand, and other accretions, which the Rhone brings down, being driven to the westward, on the side of Languedoc; and this country being every where flat towards the sea, these accumulations elevate the shore, and render the coast extremely shelving, and full of shoals. The coast of Provence, on the contrary, is for the most part steep and rocky, and besides, inclines gradually to the southward, from the mouths of the Rhone to near Toulon. The flat marshy country on the coast of the departments of La Charente and La Vendee, appears evidently to have been once submerged by the sea. This is particularly striking in one part, where a vast marshy plain is bounded to the east by a range of cliffs, which appear exactly like cliffs on the sea shore; and to the west by the sea itself, with the islands of Rhei, Oleron, and Aix constantly in sight. In the department of Finistere, the drift sand is very dangerous, especially during the prevalence of north-west winds. Cultivated fields, and whole villages with their inhabitants, have been overwhelmed by it in one night. The states of Brittany maintain, at a considerable expense, a high dyke, planted with broom, and 600 toises in length, at the foot of which the sand accumulates; but this dyke is frequently broken down. From the side of Lesneven in particular, a dreadful sandhill threatens destruction to the commune of St Pol.

The principal canals in France, are that of Languedoc, which unites the Mediterranean and the Atlantic; that of Burgundy, which joins the Loire to the Saone; those of Briare and Orleans, which unite the Loire to the Seine; and that of Calais, which communicates with the canals of the Netherlands. Referring to the article INLAND NAVIGATION for a more particular description of these canals, we shall here confine ourselves to a cursory notice of the most celebrated.

1. It is supposed, that the Romans had a design to join the Mediterranean and the Atlantic nearly at the same place where the canal of Languedoc is formed. It was several times thought of during the reigns of Charlemagne and Francis I. In the year 1598, under Henry IV. this plan was again examined, and found to be practicable. Cardinal Richelieu determined to have it executed, but was prevented by more important
FRANCE.

At length Louis XIV. appointed commissioners in 1664, to examine more narrowly the practicability of this undertaking; and in their report, the director of the king's revenue in Languedoc, M. Riequet, undertook the execution; but it is said, according to some papers on the subject belonging to Andréossi, an able mathematician, the great work was begun in 1666, and completed in 1680. Narouze is the highest place between the two seas. Here a basin 1200 feet long and 900 broad was made, which has at all times seven feet water, which is conveyed by means of a sluice towards the ocean, and by means of another towards the Mediterranean Sea. In order that this basin may never be dry, another is made 7200 feet long, 3000 broad, and 60 deep, two sides of which are formed by two mountains, and the third by a large and strong mole, through which there runs an aqueduct, that carries the water to the other basin. Great difficulties arose in the execution of this work, in consequence of the unevenness of the ground, and the mountains, rivers, and brooks. The unevenness was remedied by means of sluices, of which there are 15 towards the ocean, and 45 towards the Mediterranean. The mountains were dug through. The most considerable of them was Mount Malpas, which was dug through the space of 720 feet. The difficulties arising from rivers and brooks, were obviated by means of bridges and aqueducts. It is 150 miles in length, and has 25 falls. The most considerable is that near Beziers. This is at the end of a reach 30 miles in length, and the fall is so great as to require eight gates. It is 60 feet wide, and 6 deep: 12,000 men worked at it. The expense was L1,600,000, and it costs above L2,000 a year to keep it in order. The canal falls into the Garonne, about half a mile below Toulouse; but the navigation of the river is so indiff erent till its junction with the Tarn, being full of shoals and sand banks, that the boats upon it cannot carry any depth of lading, and it often requires many of them to take the lading of one boat from the canal. It is therefore projected to carry the canal on to the Tarn, by which means the navigation between Bourdeaux and Toulouse would be greatly facilitated. The canal of Brien, so called from the Archbishop of Toulouse, afterwards prime minister and cardinal, was planned and executed, in order to join the Garonne at Toulouse with the canal of Languedoc. The necessity of such a junction arises from the navigation of the river in the Tarn, being absolutely impeded by the weirs, which are made across it for the purpose of corn mills. It passes arched under the quay to the river, and one sluice levels the water with that of the Languedoc canal. It is broad enough for several barges to pass abreast; but this canal is seldom used, and Mr. Young remarks, that while the canal of Languedoc is alive with commerce, that of Brien is a desert.

II. The canal of Briare takes it name from a small city situated on the river Loire. It was made in order to have a communication between this river and the Seine, by means of the river Loing; for which purpose they have been obliged to make the water go over hills, by means of dams and sluices. This canal was begun in the time of Henry IV. and finished under his son Louis XIII. It begins from the Loire at Briare, and passing by Montargis and Chatillon, falls into the Loing at Cepey. Formerly the duties paid by boats amounted to very great sums annually; but they have decreased considerably since the canal of Orleans was made. By means of the canal of Briare, a communication has been opened between Paris and the sea, and even between that metropolis and all the inland provinces that are situated on the Loire, or where there are other rivers that fall into this.

III. The canal of Orleans begins at about two leagues distance from that city, at a place called Portomart, and after running through the forest of Orleans, and the adjoining plain, in a course of about 18 leagues, the water being supported by several dams or sluices, it runs into the river Loing, near the place where the canal of Briare falls into it. This canal was begun in 1682, and finished in 1692, by the care of Philip Duke of Orleans, the regent's father. During the administration of the Archbishop of Toulouse, who succeeded Calonne, the canal of Picardy was projected. It begins from the Seine, a little below Paris. In passing from St. Quintin to Cambray, in the line of the canal, the country rises so much, that it was necessary to carry it in a tunnel under ground for a considerable depth, even under many vales as well as hills. Near Belle Angloise, it is 10 French feet wide, and 12 high, hewn entirely out of the chalk rock, imbedded in which there are many flints. There is no masonry. The whole distance under ground, if completed, will be 7290 toises, or about 9 miles; the total estimate was nearly four millions of livres.

Other canals were projected and begun during the Revolution; the most remarkable of which was, a series of canals to unite the five great rivers, the Rhine, Rhone, Garonne, the Seine, and the Loire. The two former were to be united by a canal from the Rhine at Basle to the lake of Geneva, passing through the lake of Neuchatcl. Another canal from Beaucaire to the Etang de Thau, where the canal of Languedoc empties itself, was to unite both the above rivers to the Garonne; and, lastly, by the restoration of a canal formerly made from the Rhone near Lyons, to the Loire at Roanne, all these rivers were to be united; the Seine already communicating with the Loire by means of the canals of Briare and Orleans. It was also proposed to restore a canal which was made in the time of Caius Marius, to supply the wants of a safe and commodious navigation at the mouths of the Rhone. Some remains of this canal are still in existence, and are known by the name of the Fosse Maritime. This canal of Marius was cut from the port of Bourc, near the Etang de Berre at Arles; and through this his vessels could pass with security into the Rhone. The restoration of this canal would be a great benefit to the town of Arles; but these projected canals, though frequently they served to fill up the annual exces of the French government, were either not begun, or not carried on to their accomplishment.

The soil of France varies much in different parts of the kingdom; but it may be remarked, that there is scarcely any kind of soil in it, which in England could be called a clay soil. The soils may be classed as follows:

I. Fat loam, of different degrees of tenacity. The Loams, northern district of this soil extends over the provinces of Flanders, Artois, Picardy, Normandy, and the Isle of France. On the coast, it may be said to extend from Dunkirk to Carentum in Normandy. From thence to Coutances, the land is chiefly poor and stony, and continues so, though with some variations, to Brest. In a line a little to the south of the coast before Caen, the first considerable change of soil from Calais is seen. In Normandy, on the side of Alençon, rich loams on a calcareous bottom are met with. From Dunkirk to Neumours is not less than 180 miles in a right line; from
Statistics—

Soissons to Carentan is another right line of about 200 miles; from Eu, on the coast of Normandy, to Chartres, is 100 miles. The breadth of this rich district in some places, especially about Caen, &c., is not considerable, yet the whole will be found to contain not a trifling proportion of the kingdom. The fertile plains of Flanders and of Artois, are perhaps the richest parts of this valuable soil, which here consists of deep friable mould, rather inclining to clay than sand, on a calcareous bottom, bearing evident marks of having once been covered by the sea. From Paris to near Cambry, by the road of Soissons, this soil is more sandy, but equally valuable and fertile. About Meaux, there is as fine soil as can possibly exist. It consists of an almost impalpable powder, and of admirable texture and friability. In some places it is 18 feet deep, resting on a stratum of white marl. The line from Paris through Picardy is inferior; but all the arable part of Normandy, which lies within the limits above described, is a rich, friable, sandy loam, in some places of a reddish colour, and very deep. The calcareous loams are of much greater extent than the loams which have been described. To the east, they stretch across Champagne. From Metz to Nancy, all is calcareous, but not chalk. In the southern parts of Alsace, limestone land abounds. Immense districts of Dauphiny and Provence consist of the same kind of soil. Indeed, the chalk district extends east to about St. Menehould, and south to Nemours and Montargis, or even farther, for it reaches Auxerre in another direction. There is also much calcareous loam in Angoumois, Poitou, and through Touraine to the Loire. Most of the course of this river is calcareous. The chalk district, therefore, may be regarded as stretching not less than 200 miles east and west, and about as much, but more irregularly, north and south. The next considerable district of fertile soil, is the plain of the Garonne. Through all this plain, wherever the soil is found excellent, it consists usually of a deep, mellow, friable, sandy loam, sufficiently moist, and in many places calcareous. The plain of the Garonne is entered about Creissesseaux, in passing to the south from the Limousin. Its fertility increases all the way to Toulouse, where, it is uncommonly rich. Its richness, however, diminishes as we approach the Pyrenees. The breadth of this plain is everywhere inconsiderable. Another tract of rich soil is found in the vale, which stretches from Narbonne to Beziers, Montpellier, and Nîmes; but its fertility is inferior to those that have been previously described. The soil of the Lower Poitou resembles that of the richest parts of the Lincolnshire fens, and is indeed of the same nature, being for the most part marshy land drained, or gained from the sea. To the south of the Loire, in the direction of Bourgneuf, there is a tract of rich loam. Alsace, in respect to soil, resembles Flanders, but it is inferior to it. The whole fertile part of the narrow plain of Alsace, hardly presents a surface of more than 1000 square miles. The flat, and chiefly calcareous vale of Avergne, which commences at Riom, is a tract of great fertility. The whole surface is a real marl, but mixed with such a proportion of soil as to be most valuable and productive. The French naturalists who have examined it, assert the depth to be 20 feet of beds of earth, formed of the ruins of what they style the primitive and volcanized mountains. The best part of this vale reaches no farther than from Riom to Vaires, scarcely more than 20 miles. Mr Young calculates, that the whole of the fertile districts of France, which we have just described, amounts to about 28 millions of English acres.

II. The district of heath is chiefly in the provinces of Heath Brittany, Anjou, parts of Normandy, and Guenee, and Gascony. The five departments into which Brittany is divided, are reckoned to contain 1609 French square miles; the cultivated land amounts, according to some calculations, to less than one-third, and the heaths to 3,006,000 acres; according to other calculations, twofifths of the whole province are uncultivated; and some authors assert, that of 30 parts 24 are lande, which amounts to three-fifths. Some of the heaths are so extensive, that a house is scarcely seen in ten leagues. The soil of the best part of these heaths in Brittany, is commonly gravel, or gravelly sand on a gravelly bottom, of a very inferior and bare nature. In many places it rests on sandstone rock; none of it is calcareous. Anjou and Maine are equally noted for the immensity of their heaths, which are reported to extend 60 leagues in one place. The soil of these heaths is, however, in some parts tolerably good, and might be rendered useful by proper skill and labour; consisting of gravel, sand, or stone, generally a loamy sand or gravel. The Lander, as they are emphatically called, lie west from Bazadois and Condomois to the sea coast, between the country of Labour on the south, Guenee on the north, and the ocean on the west. They are divided into the greater Lander between Bourdeaux and Bayonne, and the lesser between Bazas and Montmarsan. They are sandy tracts, covered with pine trees, cut regularly for resin, broken and enlivened however with cultivated spots for a league or two. When the Moors were expelled from Spain, they applied to the court of France to be allowed to settle on, and cultivate these lands; but permission was not granted them. They are said to contain not less than 300 square leagues, or 1,468,181 English acres, occupying a large portion of Gascony. Though the soil of these Lander is among the poorest in France, it is not utterly incapable of cultivation, and even the pines with which it is covered yield from 1 3s. to 20s. an acre.

III. The district of chalk, as distinguished from the chalk calcareous loams already noticed, is chiefly in the provinces of Champagne, Sologne, Touraine, Poitou, Sain- tonge, and Angoumois. The chalk provinces contain 16 millions of acres. The soil of Champagne in general is thin and poor. The southern part, as from Chalons to Troyes, has from its poverty acquired the name of pouilliez, or lousy. Sologne is one of the poorest and most unimproved provinces in the kingdom. It is a flat, consisting of a poor sand, or gravel lying everywhere on a bottom of clay or marl, so very retentive of water, that every ditch and hole is full of it, except in the dryest seasons. Touraine is better. It contains some considerable districts, especially on the south of the Loire, in which good mixed sandy and gravelly loams rest on a calcareous bottom. Considerable tracts in the northern parts of the province, however, are of a very inferior soil, not better than the predominate soil of Anjou and Maine. Poitou consists of two divisions, the upper and the lower, the latter of which has already been mentioned as resembling the fens of Lincolnshire. The upper division is generally a thin loam, on an imperfect clay bottom,—a very inferior stone brash. A great part of Angoumois is a thin and poor chalk.

VOL. IX. PART II.
IV. The district of gravel is chiefly in the Bourbonnois and Nivernois. The gravel in the latter is of little value, three-fourths of the province being covered with heath, broom, or wood; but notwithstanding the inferiority of the soil, these provinces are reckoned by Mr. Young among the most improvable in France. They form one vast plain, through which the Loire and Allier pass. The better parts of them consist of a sandy soil, and in some places the sub-soil is calcareous. In a few spots, good friable sandy loams are met with.

V. The district of stony soils is chiefly in Lorraine, Burgundy, Franche Comté, &c. In Lorraine, there are commons of immense extent, which scarcely yield anything. From St. Menchouth to the borders of Alsace, the soil is entirely stony, but of various kinds. Most of them are of the kind denominated stony-brash in England, or the broken triturated surface of imperfect quarries, mixed by time, frost, and cultivation, with some loam and vegetable mould: much is calcareous. Districts of rich and even deep friable loams occur in Lorraine, but they are of inconsiderable extent. The soil of Burgundy varies much. The best part of it lies in the line from Franche Comté to the Bourbonnois by Dijon. Here sandy and gravelly loams predominate; but even in this part of it there are spots of poor granite soil. The subdivision of the province called Bresse, is a most miserable country. The grounds alone on a white clay or marl, amounting it is said to nearly 250,000 acres. The stony soil of Franche Comté is in general good. From Besançon to Ouche camp, the country is rocky quite to the surface. The rocks are calcareous. A reddish brown loam rests on the rock. In the hilly parts, a red ferruginous loam, sehistus, and gravel, predominate. Part of Alsace consists of soil of nearly the same character.

VI. The district of various loams, mixed with sand, granite, gravel, stone, &c. is chiefly in the Limosin, La Manche, Berry, &c. The loams of the two former are friable, and sandy; some on granite, and others on a calcareous sub-soil. Of the granite, there are two kinds; one hard, and of micaeous particles, the grain coarse, with but little quartz, hardening in the air in masses, but becoming a powder when reduced to small pieces. This is very unfertile, as neither wheat, vines, or chestnuts will grow on it. The other sort is in horizontal strata, mixed with great quantities of spar. On it these plants thrive well. This kind of granite and chestnuts appear together, on entering Limosin; but on the road to Toulouse, where there is about a league of hard granite, this tree disappears. Berry has a poor soil, though not so poor as that of Sologne. In some places it is sandy or gravelly; in other places the loams are more tenacious, lying on quarries of stone or lime.

VII. The provinces of Auvergne, Dauphiny, Provence, the Lyonnais, Languedoc, and Roussillon, contain the mountainous district. The mountains that surround the vale of the Limagne of Auvergne are various. The white argillaceous stone in the hills, between Riom and Clermont, is calcareous. The volcanic mountains (as they are deemed) are more fertile than the others, except where they are composed of tufa, or cinders, which are so burnt as to be good for nothing. The calcareous and clayey mountains are good; and the basaltic, when decomposed, form excellent clay. The base is commonly granite. Many considerable mountains, in the tract from Le Puy to Montefimar, are also what are deemed volcanic, and they are also extremely fertile. Provence and Dauphiny, with the exception of a few plains and valleys, are mountainous. Of these, the former is the driest with respect to soil in the kingdom. Rock and sandy gravels abound; and the course of the Durance is so ruined by sand and shingle, that, on a moderate calculation, above 130,000 acres have been destroyed. If Dauphiny were divided into three parts, three-fourths of one part, it is calculated, would be cultivated land; more than three-fourths of another part would be mountainous and uncultivated; and half the third part mountainous and in culture. The mountainous districts of Dauphiny and Provence are generally calcareous. The whole coast of Provence is a poor stony soil, with very few exceptions. The Lyonnais is mountainous in many parts, the soil being poor, stony, and rough, with much waste land. Seven-eighths of the province of Languedoc are mountainous. The vale lands are rich. Roussillon is in general calcareous. Much of it flat and very stony, as well as dry and barren.

Mr. Young observes, "that the proportion of poor land in England to the total of the kingdom, is greater than the similar proportion in France; nor have they any where such tracts of wretched blowing sand, as are to be met with in Norfolk and Suffolk. Thin heaths, moors, and wastes, not mountainous, which they term Lands, and which are so frequent in Brittany, Anjou, Maine, Guienne, and Gascony, are infinitely better than our northern moors; and the mountains of Scotland and Wales cannot be compared, in point of soil, with those of the Pyrenees, Auvergne, Dauphiny, Provence, and Languedoc." According to the same author, the following are the proportional areas of the several divisions of the kingdom, classed according to their respective soils:

| Rich district of the north-east, containing the provinces of Flanders, Artois, Picardy, Normandy, the Isle of France, &c. | ... | 18,179,590 |
| The heath district of Brittany, Anjou, and parts of Normandy, &c. | ... | 15,507,128 |
| The heath district of Guienne and Gascony | ... | 10,206,085 |
| The heath district of Dauphiny | ... | 25,513,215 |
| The mountainous district of Anjou, Maine, Guienne, and Provence, &c. | ... | 28,707,037 |
| The chalky district of Champagne, Sologne, Touraine, Loiret, Saintonge, Angoumois, &c. | ... | 16,584,889 |
| The district of gravel of the Bourbonnois and Nivernois | ... | 8,827,282 |
| The district of stony soils in Lorraine, Burgundy, Franche Comté, &c. | ... | 20,412,171 |
| The district of various loams in the Limosin, Berry, La Manche, &c. | ... | 8,292,444 |
| Total | ... | 131,722,711 |

It is to be remarked, however, that this admeasurement includes the whole surface of the kingdom; deductions ought therefore to be made for roads and rivers, &c. Ac-
In the north.

The climate of a extensive kingdom as France must be very various; but perhaps, on the whole, it is more favourable to the sustenance and comfort of human life, than any other in Europe. The climate of the northern districts is hotter, and at the same time more moist in summer, than the counties in the south-west of England. In the department of Finisterre, the sky is obscured by an almost continual mist. In Brest and Morlaix, it rains almost incessantly; and the natives are said to be so habituated to dampness and wet, that, too dry seasons prove prejudicial to their health. The heat in summer is never excessive, and the cold likewise is between six and seven degrees less than in Paris. The beautiful verdure of the rich pastures in Normandy, sufficiently proves the humidity of the climate of this province; but, even at a distance from the coast, the rains in the north of France are extremely heavy, and continue longer than they generally do in England. In the winter, heavy snows and severe frosts are experienced to a greater degree than in the south of England; and it is remarked there, whenever there is a long and sharp frost in the north of Europe, it is felt much more severely in Paris than in London.

The central division of France possesses a wonderfully fine climate, especially the provinces of Touraine and the Limousin. In many years there is no snow, and frosts are not frequent. There are no fogs and vapours, as in Bretagne, nor the great humidity of Normandy; and yet they are equally free from the burning sun of the southern provinces. The air is light, pure, and elastic. The spring is a continuation of such weather as is seen in England about the middle of May. The harvest begins about the latter end of June, but is sometimes so late as the middle of July. The great heats are from the middle of July to the middle of August. But the climate of the central provinces is not free from its inconveniences: all the country south of the Loire is subject to violent storms of rain and hail, the latter occasionally beating down and destroying all the corn and vintage on which it may fall. Frosts also sometimes happen in the spring, even so late as the end of May and beginning of June, so severe as to turn the leaves of the walnut trees quite black, and to render it necessary to cover the fig trees with straw. Autumnal frosts also not infrequently occur earlier in the central provinces of France than they do in the south of England. On the 20th of September 1787, Mr. Young says, there happened so smart a one on the south of the Loire, between Chambord and Orleans, that the vines were hurt by it. The high country of Auvergne is bleak and cold; and all the district within reach of the mountains of Voges are affected by the snow that falls upon them; a circumstance which sometimes occurs as late as the end of June.

In the south of France, particularly in Provence, a continuance of dry and hot weather may be expected throughout the months of June, July, and August, and a part or perhaps the whole of September. The greatest heats seldom occur till the 15th of July, nor after the 15th of September. Harvest generally begins the 24th of June, and ends the 15th of July: the middle of the vintage is about the end of September. During the continuance of the hot weather, or les grandes chaleurs, as they are called, scarcely any persons who can avoid it think of quitting their houses in the middle of the day. During the end of autumn and the beginning of winter, violent rains frequently fall; but, in the intervals between the rains, October and November may be regarded as the pleasantest months in the year. In December, January, and February, the weather is generally fine; but, after February, the vent de bise is very frequent. This wind seems to pierce through the body, and dry up all the humours. It is a strong north or north-east wind, accompanied generally with a clear sky, but sometimes with snow. It seldom lasts for more than three days at a time. This wind blows with peculiar violence and bitterness about Avignon: the winters there are sometimes rendered by it most distressingly cold; and the Rhone is covered with ice sufficiently strong to support loaded carts, and the olive trees sometimes perish to their roots. Some parts of the coast of Provence, as about Toulon and Hieres, are still milder than about Marseilles and Aix; but the northern and more mountainous parts of the province often experience very severe weather in the winter, and are as cold as England, but with a much clearer and purer air.

The chief disadvantages of the climate of the south of France are the plague of insects, and the peculiar violence of its storms, especially in the mountainous tracts. The flies are excessively troublesome in the olive district of France; they not only bite, sting, and hurt, but they buzz, tease, and worry. The mouth, eyes, cars, and nose, are full of them; they swarm on every thing eatable; fruit, sugar, milk, every thing is attacked by them in such myriads, that if they are not driven away incessantly by a person who has nothing else to do, to eat a meal is impossible. Sometimes it is absolutely necessary to darken the room, in order to keep it tolerably clear of them. In the stables, they are obliged to cherish the spiders, that their webs may catch the flies, who would otherwise be an actual torment to the horses. In the night, the gnats are very troublesome; and besides the torment of their bite, render sleep extremely difficult to be procured, by their constant and loud noise.

The author of the Essai sur la Mineralogie des Pyrenees describes a thunder storm near Bareges as extremely impetuous and formidable; the catsaracts rushing down the sides of the mountains, carrying ruin and desolation along with them; those meadows, which a few hours before were covered with verdure, now buried under heaps of stones, or overwhelmed by masses of liquid mud, and the sides of the mountains cut by deep ravines, where the track of the smallest rivulet was not before to be discovered. The hail storms in the south, and even in the central provinces of France, are not unfrequently most dreadful and ruinous in their consequences. About thirty years ago, a violent storm of hail swept a track of desolation in a belt across the whole kingdom, to the damage of several millions sterling; and no year ever passes without whole parishes suffering to a very considerable degree. In the south of France, where the hail storms are the most common and the most violent, it is calculated, that, on an average, one tenth of the whole produce is damaged by them. Young colts are some-
FRANCE.

The climate of France naturally divides itself into four zones, according to the vegetable produce which each affords. The most northern of these divisions bears a considerable resemblance, in its vegetable produce and in its climate, to England: the second differs from the first principally in exhibiting here and there a few vineyards; in the third, fields of maize begin to make their appearance; and the fourth is distinguished from the preceding by the intermixture of olives, mulberries with corn, vines, and maize. The line of separation between vineyards and no vines is at Coucy, ten miles to the north of Soissons; at Clermont in the Beauvoisis; at Beaumont in Maine; and Herbigne, near Guerande in Brittany. The line of separation between maize and no maize is first seen on the western side of the kingdom, in going from the Angoumois and entering Poitou, at Verac, near Ruffec: in crossing Lorraine, it is met with between Nancy and Luneville. If these lines between vines and no vines, and between maize and no maize, be drawn on the map of France, it will be found, that they proceed in an oblique line from the south-west to the north-east, being parallel to each other. The line which the vines form is nearly unbroken; but that formed by the maize in the central part of France, proceeds no farther north than the southern part of the Limosin. The line of olives is also pretty nearly from south-west to north, in the same oblique direction. In proceeding to the southward from Lyons, they are first met with at Montelimar; and, in proceeding from Béziers to the Pyrenees, they are lost at Carcassonne. Hence it appears, that there is a considerable difference between the climate of France in the eastern and western parts; the eastern side of the kingdom indicating, by its productions, 2° 4' degrees of latitude of more heat than the western.

Having made these general remarks on the climate of the different parts of France, we shall next proceed to lay before our readers an abstract of the most careful meteorological observations, as they respect the thermometer, barometer, wind, and rain.

I. The annual heat of London and Paris is nearly the same; but, from the beginning of April to the end of October, the heat is greater at Paris than at London. If the annual temperature of London be represented by 1000, the average degree of cold in January by 1000, and the average degree of heat in July by 1000, the annual temperature of Paris may be represented by 1028; the average degree of cold of Paris in January by 1040; and of heat in July by 1037. The annual temperature of Bourdeaux will be represented by 1090; the average degree of cold in January by 923; and the average degree of heat in July by 1189. The annual temperature of Montpellier will be represented by 1170; the average degree of cold in January by 850; and the average degree of heat in July by 1196.

In the centre of France, the greatest heat averages 27 degrees of Reaumur's thermometer, and the greatest cold 7 degrees: in the north of France, the greatest heat is 23° 2', and the least 6° 6': in the east of France, the greatest heat is 24° 3', the least 9° 5': in the west of France, the greatest heat is 24°, and the least 6°. In the south-east, at Montpellier, the greatest heat is 28° 1', the least 3° 7'. At Marseilles, the meteorological observations of nine successive years gave an average of 25° 3' for the greatest heat, and 3° 1' for the least.

II. In the neighbourhood of Paris, the barometer never continues twenty-four hours without changing. The barometer rises and falls sooner in the western districts than in the eastern. M. Burckhardt, after 15,000 barometrical observations, in order to calculate the influence of the winds on the barometer in France, found that the south wind gave, for a mean height, 27 inches 11.3 lines, while an east wind raised the mercury to 28 inches 1.9 line. He also found, that the height of the barometer on the Mediterranean shores of France was 28 inches 2.2 lines, while its height on the Atlantic shores was 28 inches 2.8 lines.

In the centre of France, the greatest height of the mercury in the barometer, on an average of several years, is 28 inches 5.7 lines, its least height 27 inches 3.3 lines: in the north of France, the greatest height is 27 inches 10.10 lines, the least 26 inches 8.5 lines: in the west, the average height of the mercury in the barometer is 28 inches 3 lines: in the north-east, at Montpellier, the greatest height is 28 inches 5.3 lines, the least 27 inches 5.5 lines. At Marseilles, the greatest height of mercury in the barometer is 28 inches 7.2 lines, the least 27 inches 3.7 lines.

III. It appears from the result of observations made by M. Cotte, at 86 different places in France, that along the whole south coast of that kingdom, the wind blows most frequently from the north, north-west, and north-east: on the west coast, from the west, south-west, and north-west; and on the north coast, from the south-west. In the interior parts of France, the south-west wind blows most frequently in 18 places; the west wind in 14; the north in 13; the south in 6; the north-east in 4; the south-east in 2; the east and north-west, each of them, in one. About Dunkirk, according to the same author, the prevailing winds are the south-west.

As, however, the result of other observations differ from those given by M. Cotte, we shall subjoin them.

According to these observations, in the centre of France, the prevailing winds are the south-west and north-east; in the northern districts the south-east wind is most common; in the eastern districts the north and south-west winds; in the west of France the north-east is the prevailing wind; in the south-east at Montpellier, the north and north-east are the prevailing winds; and at Marseilles the south-east and north-west.

IV. The mean quantity of rain that falls at Paris is 22 inches; the evaporation is generally greater than the rain; the mean evaporation being 33 inches. In the centre of France, the average quantity of rain is rather more than 20 inches; the number of rainy days in the course of the year 164. In the north of France there are 126 rainy days; in the east 145; in the west 150 rainy days; in the south-east, at Montpellier, there are 174 rainy days, and the quantity of rain is upwards of 27 inches—a proof of the violence of the rain when it does fall. At Marseilles, the quantity of rain is rather more than 21 inches, and the number of rainy days 57.
CHAP. III.

As our limits will not permit us to enter minutely and fully into the natural history of France, we shall content ourselves with noticing, in the first place, the most important and curious features of its mineralogy and geology; subjoining to this notice, an economical account of the principal mines, and a brief sketch of the mineral waters and natural curiosities most deserving of attention: in the second place, the Botany of France; and, lastly, the most interesting parts of its Zoology.

I. With respect to the mineralogy and geology of France, Modern French geographers, in a branch of that science, to which they have properly given the epithet physical, have divided the kingdom into what they call basins; that is to say into several great plains, through which the principal rivers flow, and which are formed of several ridges of mountains, either original, that is of granite, or secondary, of calcareous and other materials. Of these basins, the chief are, 1st, The basin of the Loire, and all the rivers that fall into it. 2d, of the Seine and its branches. 3d, Of the Garonne. 4th, Of the Rhone and Saone. There are likewise some smaller ones, but of much less account.

As the basin of the Seine, or of Paris as it is frequently called, is the most interesting to the geologist, and has moreover been very carefully and scientifically illustrated by the labours of Messrs Cuvier and Brogniart, in their Memoir on the Mineralogical Geology of the environs of Paris; of M. Lamaron, in his Memoir on the gypsums and their fossil bones; of M. Desmares in his description of Montmartre, and by other authors, we shall confine our account to this basin.

The basin of the Seine is separated for a long space from that of the Loire, by an extensive high plain, the greater part of which bears the name of Beauce. This plain is bounded towards the north-west by a higher and more broken district, from which the rivers Eure, Aure, Orne, Maenenne, Sarthe, &c. arise. On all other sides, the plain of Beauce overlooks every surrounding district. The slope from it, towards the Seine, is divided into two inclinations, one of which, on the west, looks towards the Eure, and the other, on the east, looks towards the Seine. These two inclined plains, however, are not straight, but in all directions unequal and rugged, the slopes are generally very abrupt, and all the ravines, valleys, and wells dug in the high parts, shew that one prodigious mass of fine sand covers the whole surface, passing equally over all the other soils, or inferior platforms, which this great plain overlooks. The edge of this platform, towards the Seine, forms the natural limit of the basin of Paris, on this side. From below the two extremities of this platform, issue two portions of a platform of chalk, which extends in every direction to a great distance, forming the whole of Higher Normandy, Picardy, and Champagne. In some parts of the two latter provinces, the chalk is covered with sandy platforms, similar to that of Beauce.

Hence it appears that the materials which compose the basin of Paris have been deposited in a vast gulf, the bottom of which is chalk. This chalk lies in horizontal beds, with flints, and is wholly, or in part, covered by certain argillaceous, siliceous, calcareous, gypseous, and alluvial strata. The basin, measuring directly from Epernay to Gesars, nearly from east to west, is 87 English miles in length, and from Nemours to the neighbourhood of Noyen, nearly south and north, it is 70 miles broad. On the south-west, from near Nemours to the mouth of the rivulet called the Maule, a direct distance of about 45 miles, it is limited by a covering stratum of Beauce sand, and in all its remaining sides by the naked chalk stratum. The chalk is undoubtedly the most ancient, and the sandy platform the most recent of the formations in this basin. Between them there are two great strata; the first, lime, either siliceous, containing no shells, or lime with coarse shells; the second, which is named by the French geologists gypsum—marley, is not generally spread, but merely scattered in spots, very different from one another in thickness and in their component parts. These two intermediate soils or strata, as well as the two extreme strata of chalk and sand, and all the veins which they have left, are partly filled by a fifth sort of soil, mixed also with marl and silex, which may be called fresh water soil, because it abounds in fresh water soils only.

If each of these large strata, however, are subdivided, there will appear 10 distinct kinds of strata in the basin of the Seine. Of these we shall give a short sketch, beginning with the lowest.

1. Chalk, either in distinct beds and with few flints, or with many layers and nodules of flint, constitutes the first formation. In it are found 50 species of fossil remains.

2. The second formation consists of plastic clay; white, grey, slate-grey, and red potter's clay, from four inches to 52 feet or more in thickness. This contains no fossils, but in some parts fragments of bituminous wood.

3. The third formation consists of sand, coarse, red, or bluish grey, without fossils;—of coarse limestone in beds, alternating with their marls and clay; the lower beds are sandy, containing greenish earth, and though hard, decompose quickly on exposure; they contain extraneous fossils in good preservation, amounting to more than 600 species;—of soft greenish earth, exhibiting on its lower surface brown marks of leaves, and stalks of vegetables;—of grey and yellowish strata, of different degree of hardness, and of building stone rocks; these contain shells;—of hard earth, containing seams full of shells;—of hard calcareous ruble marl, and soft calcareous marl beds, without fossils;—of calcareous sand, sometimes agglutinated, and containing chert, quartz crystals, and variegated crystals of carbonate of lime; and of hard calcareous ruble marl, and soft calcareous marl beds without fossils.

4. The fourth formation is still more various than the third; it consists of two distinct parts, viz. the fresh water formation, containing a mass of selenitous gypsum in thin beds, with numerous marl beds, without organised fossils; next marl strata; then a second mass of gypsum beds, with thin marl beds, containing fossil fish; then marl strata again, and above them another mass composed of three parts, with marl strata in-
Paris, there are quarries of coarse limestone and sand; and near the glasshouse here, the mass of chalk is elevated near 50 feet above the Seine, and is apparently the highest part of it in the basin of Paris; the stone is sensibly inclined towards the river; this is the only inclining stratum in the whole basin of Paris.

We shall conclude our account of this basin, with an enumeration of some of the most remarkable organic remains which have been found in it: Skeletons of unknown birds have been found at Montmartre, in the first, or upper gypsum mass; elephants bones in the alluvium, or ninth formation; fish, and fish skeletons, at Montmartre and several other places; leaves and parts of vegetables changed into silex in the alluvial sand large trunks of palm trees converted into silex, in the fourth or gypseous formation; skeletons of various quadrupeds are found, not only in the same formation, but also in the ninth formation, or the valley alluvium. Sharks teeth are found in the chalk, or first formation. Tortoise bones at Montmartre and other places of the gypseous formation. Bituminous wood, near the Seine, in the potters' clay formation, in which no other organized remains have been found. Oysters are found in the chalk strata, in the lower beds of the coarse limestone, in the freestone, and all over the gypseous formation.

Next in importance, in a geological point of view, to the basin of Paris, is the province of Auvergne. This has been cursorily referred to in mentioning the mountains of France; but it deserves more particular notice in this place. Proceeding northward from Aurillac, past a vein of chalk in a country where it would least be expected, a mountainous tract of great extent appears. These are the basaltic mountains of the province of Auvergne, the modern departments of the upper Loire and Cantal. The northern part of the chain is styled the Puy de Dome, and the southern that of Cantal: the Monts D'Or form the centre. The chief elevation is that of the Puy de Sausi: this enormous assemblage of rocks covers an extent of about 120 miles. It is a most singular and interesting tract, independently of these high mountains: great part of it is extremely rugged and impassable, the whole surface being covered with blocks of granite or basalt. A stratum of basalt seems to have covered a large part of this district, the remains of which are seen on every eminence, forming horizontal crests on the same level. There are about 100 cones, besides numerous longitudinal ridges, all of which are basaltic; and at the base of some of these cones, M. D'Aubuisson discovered currents of the same substance. Near St Chamon some masses of basalt present the appearance of columns bent in an extraordinary manner. One of the most celebrated of these cones is called La Tour d'Auvergne. Among the scoria, about three leagues from Clermont, are the charred remains of many trees. No appearance of a crater is to be observed any where.

Such is a general description of the basaltic district of Auvergne; according to some it is of volcanic origin; but a chain of volcanoes, such as on this supposition the cones would indicate, it has been asserted, would be too bold even for conjecture. It is foreign to the purpose of this article to discuss this question; we shall therefore only observe, that, according to Dolomieu, who examined this district very carefully, the lavas of Italy and Auvergne are perfectly analogous. There is, however, a marked difference in the styles of the two volcanic fields. In Italy the subordinate hills are disposed in
groups, round the principal volcano; whereas in Auvergne, the elevations are detached, and seemed to have formed separate volcanos. In Italy, the ashes, scoria, &c. have formed immense accumulations over an immense extent of ground, on which streams of lava have been afterwards induced; whereas in Auvergne, the ashes and scoria lie on the original granite soil. This district has also been examined by another French geologist, M. Mutheron, who was bred in it; and he states, in reference to its origin, that the granite hills contain in their bosom large heterogeneous masses, and veins indubitably volcanic. That the ancient volcanos are frequently approximated to each other, and that the fragments of granite detached by eruptions, are more or less calcined, opaque, or deprived of their water of crystallization. Mr Birkbeck, one of the latest and most acute and observant English travellers in France, is of opinion that the cones and longitudinal ridges of basalt in Auvergne, have been formed entirely by subside, and are the venerable remains of the ancient surface.

The geology of the Pyrenees in some respects is interesting. To the surprise of mineralogists, they present calcareous appearances, and even shells, near or upon their highest summits, which are in the centre of the chain. The Abbé Palasso, in his Essay on the mineralogy of these mountains, gives a mineralogical chart of them, from which it appears that the granite does not occupy one fifth of the horizontal surface on the north side of the ridge; reckoning from one end of it to the other; and many great tracts, even of the central parts of the Pyrenees, contain no granite whatsoever; and not a few of the highest mountains consist entirely of calcareous schistus. In other places, blocks of granite are interspersed with vertical bands, argilaceous and calcareous, the latter primitive or secondary, and supplying the marbles of Campan and Antin, of beautiful red, spotted with white. The colour of the general mountain mass is grey. The summit of Mount Perdu, which is the highest elevation of the Pyrenees, abounds in marine exuviae; hence La Peyrouse infers, that it, and all that central and most elevated portion of these mountains, which also include a profusion of petrified marine bodies, distributed even in large families, have been formed under the waters of the sea. With the remains of marine bodies, the bones of quadrupeds are mixed. On Mount Perdu, there is also a deposit of sand-stone. It further appears, that in the Pyrenees there are, 1. The primitive rocks of limestone, uniformly destitute of organic remains, alternating with beds of granite, porphyry, trap, hornstone, and petroclay, all of the same formation, and a common origin; and, 2. Limestone, containing vestiges of petrified animals, which is never blended with the prismatic rocks, but is often incumbent on them; this is of different origin and more recent formation. 3. That this secondary limestone, being found covering the summits even of the granite, porphyry, &c. must have been deposited there by the water; and, lastly, that the sandstone already mentioned is the last deposit from the waters. It may also be remarked, that the inclination of the primitive beds is in a contrary direction from that of the secondary rocks.

Our remaining illustrations of the mineralogy and geology of different parts of France, must be very short and unconnected, as we cannot pretend to give full and connected views on this subject. At Marly La Ville, the following are the order and depths of the respective strata. 1. Earth, mud, and sand, 15 feet. 2. Earth and gravel, 2 feet 6 inches. 3. Mud and sand, 3 feet. 4. Hard marl, 2 feet. 5. Marly stone, 4 feet. 6. Powder marble with sand, 5 feet. 7. Sand, 1 foot 6 inches. 8. Marl and sand, 3 feet 6 inches. 9. Hard marl and flint, the same depth. 10. Gravel or marl in powder, 1 foot. 11. Eglantine, 1 foot 6 inches. 12. Marly gravel, the same depth. 13. Stony marl, 4 feet 6 inches. 14. Sand and shells, 1 foot 6 inches. 15. Gravel, 2 feet. 16. Stony marl, 3 feet 6 inches. 17. Powdered marl, 1 foot 6 inches. 18. Hard stone, 1 foot. 19. Sand and shells, 18 feet 6 inches. 20. Brown freestone, 3 feet. 21. Sand, 22 feet 6 inches,—in all, 100 feet. In the hills near Etampes, a considerable town in the department of the Seine and the Oise, seated on the river Loet, the strata are very different; exhibiting, 1. Vegetable earth, 4 feet. 2. Marl and turf, 135 feet. 3. Freestone, marl, and shells, 12 feet. 4. Brown pebbles, 4 feet. 5. Marl and shells, 6 inches. 6. Sand and grit, 45 feet. 7. Sand and rounded pebbles, 18 feet. 8. Sand and shells, 6 feet. 9. Sand and gravel, 16 feet. 10. Tufa and shells, 4 feet. 11. Soft strata, 4 feet. 12. Marly clay, 8 feet,—in all, 250 feet 6 inches.

Between Rouen and Louviers, the Seine has worn its channel through about 30 strata of chalk. The strata are from 18 inches to two feet in thickness, and are divided by cliffs. The chalk is hard and stoneware. These hills differ from the chalk cliffs of England, from their horizontal position, the number of their strata, and the thickness of the layers of flints, as well as the softness of the chalk. To the south of Moulins, no more cliff appears. At St Urban, near Vienne, there are granite pebbles in vast beds, 800 feet at least above the level of the Rhone. A few miles to the north of Vienne, the mountains of granite give place to stratified rocks of sandstone and limestone. Opposite this town is a remarkable rock of crumbling sandstone, in horizontal strata. Between the same place and Avignon, the Rhone flows between mountains of stratified limestone. Avignon itself stands on a bold rock of limestone, of immense blocks, in appearance nearly resembling granite. In leaving the Pyrenees, and descending from Foix to Pamiers, alluvial hills of quartzose sand, or of schist, assuming the character of clay, with some calcareous rocks, are found. At Caylus is a stratum of chalk between strata of limestone, which occurs in other parts of France, but is uncommon if not unknown in Britain. In a northerly direction from this is the volcanic country of Auvergne, which has been already noticed.

Having given this cursory description of the geology and mineralogy of some of the most interesting parts of France, we shall now proceed to offer some miscellaneous remarks, which may serve to fill up any omissions of importance that may have occurred.

1. With respect to primitive and secondary compounds. The principal localities of granite and gneiss have been already mentioned. Jasper is found in the south of France, reposing on granite. Porous porphyry, appearing as if it had undergone the action of fire, occurs in the mountain of Estrete in Provence, on the road from Frejus to Antibes. Primitive trap, alternating with granite and with gneiss, occurs near St Malos. Secondary limestone, in vast masses, irregularly rifted, in the Varvaux. The secondary limestone of Mount Perdus has been already mentioned. The gypsum of the quarries near Paris has also been noticed; but it may be added, that lenticular gypsum is a curious variety, that seems peculiar to Montmartre; that crystallized gypsum is al-
France.

Auvergne, matrix primitive having the veins, and metallic with the titanium genus, has been found lining the cavities of a vein, accompanied by quartz and feldspar, in a primitive rock in Dauphiny.

3. Having enumerated the most remarkable of the compound rocks, and metallic veins and ores, we shall now notice the other mineral substances, not included in these two classes.

Earth and stones. Of the genus Zircon, the hyacinth has been found in the rivulet Expilly, in the department of the Upper Loire. Of the silicious genus, Olivine is found in the Vivarais; granite in Brittany; the emerald, of a bad colour and confused crystalization, however, has lately been discovered in the vicinity of Limoges; the beryl, in a large vein of quartz, flint, and limestone, traversing graphic granite; the tourmaline, the pista-zite, or glassy actinolite of Kirwan, in Dauphiny, on the surface and in the fissures of an argillaceous rock, accompanied by quartz, amiantus, and feldspar, and in the Pyrenees in limestone; thumstone in the Pyrenees; the amethyst in Auvergne; aventurine, a variety of common quartz, held in considerable estimation, has been found near Vastes, in the department of the Two Sevres, in the form of rounded stones, that are reddish. In the department of Jura, globular masses of flint occur, with cavities containing sulphur. Chalcedony, in thin layers, alternating with gneiss; and agate, imbedded in granite, containing nodules of the same granite, and penetrated with iron pyrites, have been found near Vienne, in the department of the Isere; menefite, the pitch-stone of Kirwan, at Menil Montant, near Paris; veins of prehnite, in Dauphiny; laumontite, or efflorescent zeolite, in the lead mines of Huelgoit, in Brittany; andalusite, the adamantine spar of Kirwan, was first discovered in the granitic rocks of Forez, in the department of the Rhone and Loire, where it occupies a vein of common feldspar; hollow spar, a subspecies of feldspar, is imbedded in argillaceous schistus, in the mines of Brittany.

Of the argillaceous genus, porcelain earth is found at Limoges and Beynac. Adhesive slate forms considerable beds at Menil Montant, in which beds the menilite already noticed is found. The mountain of Auvergne, near Frejus, which abounds in mineral productions, presents large quantities of a sort of micaceous sand, resembling silver and gold, which, by reflecting the rays of the sun, produces the most brilliant effect. So rich do these sands appear, that a representative of the people, not versed in the study of mineralogy, crossing this mountain in 1795, eagerly collected a quantity of this beautiful sand, and carried it with him to the Convention, as a proof of the negligence of the administrators of the department of the Var, who trod under their feet treasures adequate to sustain the expense of the war against all the kings of the universe. Basalt, lava, indurated lithomarge, &c. are also found in France.

Snow of a very bright red colour has sometimes been found on the summits of the highest mountains. The matter which colours it, burns with a smell similar to that of a great many vegetable substances. Saussure, who often collected such snow on the Alps, was induced, by this property, as well as by its being found in summer, and in places where a great many plants were...
in flower, to consider the colouring matter as the farina of some plant. Ramond, who found this dust on the snow of the Pyrenees, having remarked that it is heavier than water, suspected it to be of mineral origin; and on analysing it, he found that it arose from a decomposition of certain micas.

Of the magnesian genus, fullers' earth, though not so good in quality, nor so abundant as in England, is found in France. There are also other species of this genus, but none that require particular notice.

Of the calcareous genus, the great body of chalk which traverses France from Champagne to Calais has already been mentioned, and also the marbles of the Pyrenees, and the marls and gypseum in the vicinity of Paris, as well as the other most interesting species of this genus, that occur in France.

Of the barytic genus, sulphate of barytes has been found in the province of Auvergne; and in 1798, M. Lelievre discovered the sulphate of strontian in a strated mass; it was about the depth of 15 or 16 feet in clay, which had been digging for some years before at Bouvron near Toul.

Petroleum and asphaltes are found in great abundance in Alsace, in a bed of sand, but upon two beds of clay or argillaceous schistus. Auvergne also contains abundance of fossil pitch, which exudes in a warm season from a rock impregnated with it through its whole mass.

The organic remains found in the basin of Paris have already been noticed. They also occur in other parts of France; but we can only afford room for the following instance. At St. Chamant, near Lyons, is found an argillaceous schistus covering a bed of coal, every lamina of which is marked with the impressions of the stem, leaf, or other part of some ferns, all of species not only not found in France, but peculiar to the East Indies, or the warmer climates of America. The fruit of a tree which grows only on the coasts of Malabar and Coromandel was also found here.

We shall now proceed to the economical account of the mineral productions of France.

Mines.

The only mine of gold which in modern times has been wrought in France, was discovered in 1791, at Gardette, in the valley of Oysans, in the department of the Isere. This was a regular vein of quartz, traversing a mountain of gneiss, and containing auriferous sulphuret of iron, and some fine specimens of native gold; but it was not sufficiently rich to defray the expense of the operation. Many of the rivers of France contain auriferous sand, as the Rhine, the Doubs, the Garonne, the Ardeche, and several of the small rivulets which flow from the Pyrenees; and it is said that gold is also found among the black sand, and particles of morassy iron ore, in the neighbourhood of Paris.

There are silver mines at St. Marie-aux-mines in Alsace, at Gibromagny in the department of the Upper Rhine, near the mountains of Voges, also a part of Alsace; and at Allemont in Dauphiny; but silver is most commonly attached to the lead and copper ore: and the former metal in some parts of France is particularly rich in this respect, containing for every quintal of lead nearly 16 ounces of silver.

Iron.

Iron is found in abundance, particularly in the northeastern departments. The ore is not frequently found in large lumps on the surface, and the strata are most commonly but a few feet below it. The Pyrenees abound in large banks containing iron ore. There is an iron mine of considerable repute at Vicedosse, situated very high in these mountains, about 15 miles to the south-west of Tarascon, and not far from the frontier of Spain. The "chantiers," or places where the ore is dug, are some hundred fathoms deep; and the passage to them in many parts very narrow and steep. Up these passages the ore is brought with amazing toil, on the backs of the miners. Some carry 100 lb. some 120 lb. and some even more, according to their strength. The mine is the property of government. There are generally 400 persons at work in it, under inspectors, but paying themselves by the sale of the ore to the forge masters. It is miserably wrought, without a single improvement, Mr. Birkbeck supposes, since the days of Julius Cesar. The ore is rich, and containing calcareous spar, is reduced without the addition of any other substance. It lies very irregularly, under line of a schistose appearance. The mass of ore is in some parts upwards of 60 feet in thickness. The miners are mostly proprietors of land. The whole surface of the mountain is divided in patches of different dimensions, all cultivated and watered with the utmost assiduity, and clothed with luxuriant vegetation. There are also abundant mines of iron in Upper Languedoc, in the mountains of the Rouergue, which bound the western part of the province; and in the county of Foix, which joins Languedoc to the south, there is a mine of iron, so extensive, that it has supplied 40 foundries for upwards of two centuries. In these parts, the furnaces to the iron foundries, instead of being blown with bellows, are supplied with a current of air, by means of water precipitated through a vertical tube, to which is given the name of a trombe, the same word which is used in France for a water spout. This practice is of very ancient standing. There are also iron mines in Franche Comté, Lorraine, Champagne, Berri, &c. Great attention has been paid to the working of all the iron mines, since the Revolution. The number of forges for the working of iron and steel are computed at nearly 2000; but these included the forges in those departments in the north-east, which no longer belong to France. Before the Revolution, France imported iron. The annual value of 11 or 12 millions of livres; a great quantity of steel is still imported from Germany into France. There are some rich copper mines in the Pyrenees, in the departments of the Rhone and the Upper Alps, in the mountains of Rouergue, in the departments of the Loire, the Lozere, and the Ardèche, and in Saint Marie-aux-mines, near the mountains of Voges. The principal copper foundries are at Saint Bel, Lyons, Avignon, Bedarieux, Montpellier, &c. Formerly almost all the copper used in France was brought from Sweden.

Two-thirds of the lead of France are from Brittany, Lead, particularly the mines of Pouliauven and Huelgoet. There are also lead mines in the department of the Channel; but they have been repeatedly abandoned, in consequence of a deficiency of coal for working them. Mines of lead also occur in the departments of the Maritime Alps, the Lozere, Ardèche, &c. and in the mountains of Voges. Most of those that are worked, yield silver at the same time.

France possesses mines of antimony, which might Antimony, suffice for supplying all Europe with that commodity. The principal ores are those of Creuse, Cantal, the Higher Loire, the Vendée, the departments of the Ardèche and Allier, and at Allamont in Dauphiny.

Zinc is the most common of the French semi-metals. Zinc. It is found in three states in the mines; viz. in blende,
The strata of Provence extend over a district of more than 20 leagues in length; but the thickness of the seams seldom exceeds two or three feet. This situation of coal is curious, as it puts beyond a doubt the existence of coal in limestone, which had been long denied. The coal of Alais, a town in the department of Gard, near the foot of the Cevennes, presents a mixture of calcareous matter, and is often burnt for the express purpose of obtaining lime. The geology of this provincial district of France also furnishes an instance of the occasional interposition of layers of peat earth between those of coal, though it may be doubted whether the alleged peat may not more properly be classed with vitriolic or bituminous earth, or even perhaps with fossil wood. Many of the coal strata in France are accompanied by primitive rocks; while most of those in England and Flanders are insulated in secondary soil.

The other most considerable coal mines in France are those in the Lyonnais at Forez, in the department of the Rhône and Loire, in Burgundy, Auvergne, and Franche Comté. The mines in the Lyonnais, and those at Forez, are among the most important: they are situated in a valley extending from the Rhône to the Loire, in a direction from north-east to south-west, between two chains of primitive mountains, occupying in length a space of six or seven leagues, from Rive-de-Gier to Firmines. In one part of the valley, in the neighbourhood of St. Etienne, the strata are nearly horizontal, and the medium thickness of the coal stratum is from three to six feet; near the Loire, there are from 15 to 20 of these strata. The strata at Rive-de-Gier are almost vertical; their thickness is very unequal; sometimes amounting to upwards of forty feet, and seldom less than three feet; the quantity of course is immense, and the quality excellent. In the neighbourhood of Rive-de-Gier, forty mines are generally at work; and in one year, they produced 1,600,000 quintals of coal. As Liège no longer belongs to France, it is not necessary to notice its extensive and valuable mines of coal in this place.

In French Hainault, there are some coal mines at the villages of Fresne, Coule, Augin, &c., which have been wrought for a considerable length of time: there are also mines in the Bourbonnois, Boulonnais, Nivernois, where coal is found within three feet of the surface; at Carmaux; between Bennue and Autun in the department of the Cote D'Or; in several places in Anjou; in Brittany, near Chapelle; Montreuil, and Niort; at Livry in Lower Normandy; and in the neighbourhood of Paris.

Buffon estimated the coal mines which were constantly wrought in France, in his time, at 400; and added that 200 more were capable of being wrought. In 1798, Lefèbvre published a report of the different coal mines in France; the substance of which we shall give, though of course it includes the mines in those departments, particularly those formed out of the bishopric of Liège, which no longer belong to France.

From this report it appears, that coal was actually wrought in 47 departments of the empire; that indications of its occurrence had been traced in 16 others; that the yearly produce of the mines of 34 departments had been fairly estimated at 77,600,000 quintals; that if 51,600,000 quintals were to be allowed for the undetermined departments, the total number of quintals would be 81,700,000, which, if converted into money on the coal grounds, would fetch 32,300,000 francs; and that more than 60,000 individuals earned their subsistence at the coleries, independently of those who were engaged in the carriage and exportation of the commodity.

In the annual exposé of the French government for the year 1814, (the first year after Louis XVI ascended the throne,) a very flattering picture is drawn of the state of the mines in France; for it was the policy as well as the interest of all the various rulers during the revolutionary era of that kingdom, to pay particular interest to the working of the mines; and, for that purpose, all the scientific talents, experience, and skill, which could possibly be brought to bear on their management, was, if the expression may be allowed, put in requisition. According to this exposé, which of course must be understood as applying exclusively to France proper, there were, in 1814, 478 mines of different kinds actually working, which employed 17,000 men, and produced a raw material of the value of 26,800,000 francs, and a revenue to the state of 251,000 francs. From the small number of men employed, as well as from the estimate of the value of the raw material, as well as the expression raw materials itself, this statement must be regarded as not including coal mines, but only mines of the different metals found in France.

Jet is found in the departments of the Aube, the Jura, and the Ardèche; but principally in the neighbourhood of three villages, in the department of the Aube, in the south-west of Languedoc. It is in beds
like coal, but not continuous, and is sometimes rendered impure by a mixture of pyrites. It is for the most part met with in a kind of rusty earth, of an ash colour, and sometimes occurs in masses of the weight of 50 lbs. about 5 or 6 tones under the surface of the ground. It has been manufactured from time immemorial, in the three villages alluded to, into rosaries, crosses, buttons for black dresses, &c. being an article of great consumption, chiefly in Spain. In 1786, it employed more than 1200 workmen, and the annual supply of the mineral was computed at 1000 quintals. Besides exports to Germany, Italy, and the Levant, Spain imported these jet manufactures to the annual amount of 180,000 litres. Latterly, however, the mines in France seem to have yielded a diminished supply, as jet was imported from Spain for the manufactures. Solid bitumen, or asphaltum, is obtained chiefly in the departments of the Ain and the Lower Rhone; glutinous bitumen, called pisolphaltus in the department of the Puy de Dome; liquid bitumen, called naphtha and petroleum, in Auvergne, (as has already been noticed,) and in the departments of the Herault, and the Lower Pyrenees. Rosin is procured along the banks of the Rhone from Seisal to Fort Eclusum. Alum is found in considerable quantities in the department of the Aveyron. In the province of Berry, ochre, which is used for melting of metals, and in dyeing. Beside the extensive morasses of peat earth along the Somme, and Esoane, which seem to have been used for fuel at an early period, there are many other situations, particularly in the north-western departments of France, where this combustible substance is found in greater or less abundance. Within these few years, in consequence of the increasing scarcity of fuel, the intention of the government, as well as of the public, has been called to the state of the tarbarsies in various parts of the country. Turquoises, scarcely inferior to those of the East, are among the fossil productions of the mountains of the Rouergue, already frequently mentioned: the principal mine is at Simozac. The remains of the species of animal, of which the teeth tinged by copper afford the turquois stone, are found in the department of the Ain. Vitriol, ochres, sulphur, and excellent argil for potteries, are also found in these mountains. Indeed all sorts of earths and sands used in manufactures, as kaolin or porcelain earth, arenaceous quartz, pizzolane, &c. abound in France. Besides the quarries of freestone in the immediate neighbourhood of Paris, there are many others in the kingdom, particularly near Strasburg, towards Saverne, and along the Rhine. These quarries afford hard and solid stones of a surprising size, some being 24 feet long and 6 feet broad; and quarries of a kind of jasper near Salins in Franche Comtè, some blocks from which are so large as to be capable of making columns of from 12 to 15 feet high. The marble quarries of the Pyrenees have been already mentioned.

The salt springs at Salins in Franche Compté; about six leagues south from Besançon, and as many east from Dole, demand our notice in this place. The highest hills which surround Salins are of primitive limestone, which is very hard, mixed with clay, and has a testaceous fracture, but contains no shells. Contiguous to these hills are others, composed of limestone of secondary formation, and abounding with shells. In this secondary limestone are found masses and thin layers of gypsum, which is quarried in different places. There are three distinct salt springs, the strongest of which contains 25 per cent. of salt, and the weakest only one. As not only the quantity, but also the strength of these sources, is increased, very soon after rain, it is probable that they proceed from some natural magazine of rock salt in the neighbourhood. Such are the mineralogical circumstances connected with these springs, as given by Hassenfratz, in his "Observations on the Salt Springs of Salins." With respect to the economical circumstances relating to them, we may observe, that the Great Salt-work, as it is called, is a strong place by itself in the middle of the town, surrounded with thick walls, round and adjoining to which are buildlings for the wheel works, cranes, &c. which serve to raise the waters, and for the furnaces, &c. employed in the manufacture. In other places are three great stone reservoirs, which together hold above 25,000 hogsheads of water: there is also a fourth cistern in the ground, which holds above 15,000 hogsheads.

The whole extent of the subterranean caves is about 400 feet in length, by 50 or 60 in breadth; the descent is by 61 steps. At the bottom of this cave, there issue from the same rock, within the space of 14 feet, six springs of salt, and two of fresh water. In another part of the cave are six or seven springs of salt water, along with ten or twelve of fresh water: the waters, of course, are kept quite separate. The salt water is collected in a basin, whence it is raised by wooden pails, linked together about a great wheel, which is turned by a horse. These pails are filled in the basin; and whilst some are filling, the others empty themselves into another basin that stands higher, and out of which the water runs into the stone reservoirs. The different springs have different degrees of saltness. If 1 cwt. of water does not produce at least 18 or 20 lb. of salt, the profit will not answer the expense. The overseers of the springs try the strength of the waters once a week, that, upon their report, those who mix them may do it in due proportion, according to their respective degrees of saltness. In the evaporating process, there is nothing that requires notice: The surface, or uppermost part of the salt, which, for its whiteness, brightness, and strength, is called sel tiré, is sent to Switzerland in casks; and sold at a moderate price; the remainder is moulded into cakes of three or four pounds weight. The salt is manufactured at Montre and Arg, as well as at Salins. There are also salt springs at Dieuze and Chateau-Salins, in the province of Lorraine, and salt refineries at Mouvyen, in the district of the Three Bishoprics, as it is called.

Sea salt is made in great abundance on the coast of France, particularly on the coasts of Brittany, Saintonge, Aunis, Normandy, Poitou, and Languedoc. The salt-marches of Saintonge and Aunis produce the best salt in Europe. In the department of the Channel, salt is prepared from sea sand on a very extensive and beneficial plan.

The principal mineral waters in France are those of Aix, Bagneres, and Béziers. The waters of Aix in Provence must have been known to the Romans, as the name of the town is derived from Aqua Sextia, from the baths established in it by C. Sextius Calvinus. The source of the baths, however, was lost, till the beginning of the last century, when it was discovered in digging for the foundation of a house, just without the city wall. The temperature of the water is about the same as that of the Queen's bath at Bath; its contents similar to those of Aix la Chapelle, principally sulphur, carbonate of lime, and nitrate of soda. Bagneres, in the eastern part of Guienne, derives its name from its baths, which were frequent by the Romans. The hottest spring raises the mercury in Fahrenheit's thermometer to 123°, while the most moderate causes it to ascend only to 86°. Two are exactly equal in heat to
that of the human body; ten are below it, and eighteen are above it. The waters of the Queen's bath are strongly purgative; those of Salut and Le Fré, diuretic and cooling. The degree of heat in Salut is 88°. Bagneres is situated in a frightful chasm of a valley, shaded on both sides by rude, barren mountains, and the Baston, a foaming torrent, filling the hollow. The situation is such, that the inhabitants dare not stay here during the winter, but remove all their furniture, and even their doors and windows, to such houses as are most out of the reach of mischief from the floods and avalanches. The mineral waters issue out of a hill in the centre of the village, and are distributed into three baths: they are strongly sulphureous, and consequently very fetid. Their degree of heat is from 80 to 112°; they are greasy to the touch, and tingie silver black. The waters of St Sauveur, near Luz, are not so hot as those of Bagneres, but their taste is still more nauseous. There are other mineral waters at Cauterets, in the midst of beautiful scenery. The hottest spring raises the mercury to 118°; in the coolest, it falls to 69°. Bagneres de Luchon may also be mentioned: it is a small town on the river Neste, completely hemmed in by lofty mountains on the borders of Catalonia. The baths are at a small distance from the town, and near the springs, which issue out of a rock, and are three in number, varying materially in their degrees of heat, but all tepid. One of them is separated by a plank from a copious stream, which furnishes the coldest and purest water in the valley. Their streams are suffered to unite soon afterwards, to fill the tepid baths. The other mineral waters of my note in France, are those of Forges, Viclbi, Bourbonne, Balsuc, and Plombieres.

Natural curiosities.

La Cras.

Of the natural curiosities in France, we shall principally confine our attention to those which are interesting from their connection with its physical geography. In this point of view, the plain of La Cras claims our first notice. It is situated on the east side of the Rhone, between Salon and Arles; its form is triangular; it covers an area of about 20 square leagues, or 136,750 English acres. This area is covered entirely with quartz of gravel, some of the size of a man's head, but of all sizes less, and the shingle of the sea shore is not more barren of soil. The basis of the whole plain consists of horizontal layers of pudding stone; and as, on examination, the stones on the plain have been ascertained to be exactly of the same kind, there can be little doubt that the vast body of gravel spread over this singular plain has originated from the destruction of layers of the same rock, which may perhaps have risen a great height above what is now the surface. This is the opinion of Sauvassie, and is more probable than the suppositions, that the gravel has been brought down by the Durance from the Alps of Dauphiny; that the Rhone has formed it; or that it is the work of the sea. This plain was known to the ancients by the names of the Campus Lapidius, or Campus Hercules. The origin of the first name is sufficiently obvious; the latter was derived from its having been the reputed scene where Hercules, fighting with the sons of Neptune, and in being in war of weapons, was supplied from heaven with a shower of gigantic stones.

There are some singular caves in France, particularly that in Franche Comté, near the village of Beaume, and those of Roquefort; the former is remarkable from its containing a glacier. This cave is at the bottom of a small valley, in the middle of a thick forest. The month is 45 feet wide, and is level with the valley. After a long and steep descent, there is a hall 100 feet high, and from this a passage leads to the chamber containing the glacier, the descent to which is by a ladder of 40 feet. In this cavern are stalactites of solid ice, which are in some parts nearly joined by pillars of the same material, rising from a magnificent pedestal on the floor. Reaumur's thermometer, which on the outside of the cave was at 20°, degrees, fell within it to 1°. With respect to the caves of Roquefort, the air issues from among the fragments of a calcareous mountain. In the month of October, the thermometer of Reaumur descended, in these caves, to 54°, while it stood at 15° in the open air; and Chaptal, on the 21st of August 1787, with a good thermometer, which stood at 29° in the shade in the open air, found the temperature of a rapid current of air in one of the caves to be 4°. He was informed that the thermometer had been seen, in that exposition, as low as 20° above zero. The hotter the external air, the cooler the caves are found to be, because the current is then stronger. These caves are used in the manufacture of a peculiar and highly esteemed cheese.

The fountain of Vaillans, immortalized by Petrarch, is not uninteresting to the naturalist. At the termination of the valley of Vaillans, is an immense perpendicular rock, measuring 600 feet in height from its base; within this rock is the cavern, in which rises the fountain of Vaillans. The entrance to the cavern is 60 feet in height; before it rises an immense rock, which conceals it: through this rock the water filters, pushing out at its base in innumerable little streams. Such is the ordinary state of the fountain; but when, in the spring, the snows of the mountains melt, the waters rise above the rock, and forms an immense cascade. In the territory of Meyrargues, in the diocese of Aix, is a spring called the fountain of La Foux, which has the same periodical risings as the fountain of Vaillans, but it is little known.

In the department of Ardeche are several natural curiosities; the bridge of rock, under which the river of Ardeche passes; the grottos of Vallon; the gulf of Goule; with many singular basaltic columns, &c.

II. In describing the botany of France, we shall be principally indebted to the sketch of it given by Mr. Aikin. Notwithstanding the pains that have hitherto been bestowed by French naturalists in illustrating the Flora of their native country, it still remains in an imperfect state. Particular districts, as the environs of Montpellier, Lyons, and Paris, have been surveyed with considerable accuracy; but many chasms must yet be filled, before a comprehensive history can be made out of the vegetable productions of France. So great, indeed, is its extent, and so various its climate, that probably more than half the European species of plants may be found within its boundaries. The bleak shores of the north; the fertile plains on the Belgian frontier; the rich vales of the Loire, the Rhine, and Garonne; the towering heights of Auvergne; the exterior ridges of the Alps and Pyrenees; the sunny exposure of the Mediterranean coast; offer such striking differences of soil and temperature, as evince at once a most abundant and diverseogue of indigenous plants. That country which produces in full and eternal perfection, wheat and apples, maize and grapes, oranges and olives, figs, date, and the myrtle, must doubtless exceed all other European countries of equal extent, in the variety and richness of its vegetable treasures. The southern and eastern pro-

* So called from the celebrated Queen of Navarre, who here lays the scene of her Tales.
vinces of France being those which have been the most carefully explored, as well as containing the most interesting plants, are chiefly referred to in the following lists.

The species belonging to the large class of compound flowers, including nearly the whole of the class Symgnesiac of Linnaeus, are very numerous. Of these, several are introduced at present into our flower-gardens; such are Echinops sphaerocephalus, globe thistle; Onopordon Illyricum, woolly thistle; Carlina corymbosa, racemosa, and lanata, all three species of the Carlina thistle, and natives of Provence; Atractylis cancellata, distaff thistle; several species of Centarea, among others C. benedicta, blessed thistle; Santolina incana, lavender cotton; Artemisia rupestris, mountain southernwood; and A. abrotanum, common southernwood; both of them plentiful on the rocks of Dauphiny and Provence. Tussilago and Cacalia alpina, alpine coltsfoot, and cacalia, abounding on the mountainous frontiers of Savoy and Piedmont; Centaurea centauroides and latens, blue and yellow Lion's foot; Aster alpinus and amellus, Michaelmas daisy. A few suculent vegetables that grow wild in Languedoc and Provence, but are cultivated in our kitchen-gardens, arrange themselves under this class; for instance, Cynara scolymus, artichoke; Tragopogon porrifolium, salsify; and Scorzoneria hispanica, scorzonera. Two or three are used in medicine, such as Tanacetum balsamita, costmary; Arnica montana, leopard's bane; Anthemis pyrethrum, pellitory of Spain, found in the neighbourhood of Montpellier.

The cucumber, the melon, the gourd, and other kindred genera, though cultivated largely, and with great ease, in the south of France, are yet natives of hotter climates: only one of this natural family, the Monardica elaterium, squirting cucumber, properly belongs to the French flora: it occurs in a truly wild state, on low loose rocks, in Provence and Languedoc.

Of the ringent or galiated plants, numerous species are natives of France, not many of which, however, have found their way into English gardens. The following are almost the whole that are in any request for their beauty, or use, all of which are natives of Languedoc, Provence, or Dauphiny. Acinus spinosus and mollis, prickly and smooth Anemone; Antiirrhinum Montpessulanum, smooth Antirrhinum; Pulsatilla chamae-umbra; Polygonum flavescens and incarnata, lowwort; Origanum Creticum, cretan origany; Melissa officinalis, balm; Hyssopus officinalis, garden hyssop; Lavandula stoechas, spike lavender; Rosmarinus officinalis, rosemary; and Salvia officinalis, garden sage.

The nearer, in general, any country is situated to the tropics, the greater is the abundance and beauty of the bulbiferous or liliaceous plants that inhabit it. The south of France is particularly rich in these splendid and fragrant vegetables, several of which have been naturalized in our gardens, and constitute their principal ornament. Of the genus Allium, garlic, no less than 36 species are natives of France, several of which have been admitted, for their beauty, into English flower gardens; of these the A. Montpessulanum, Montpellier garlic, is perhaps the chief. The large branched asphodel, Asphodelus ramosus, a flower of great beauty and poetic fame, is by no means uncommon in Provence. Hemerocallis fulva, tawny day lily; Hyacinthus botryoides, clustered hyacinth; Ornithogalum pyramidal, spiked star of Bethlehem, are all found in the Mediterranean provinces of France, as are also Lilium bulbiferum, pomponium, and martagon, the orange, pompons, and martagon lilies; Erythronium dens canis, dog's tooth violet; Bulbocodium vernum, vernal bulbocodium; Veratrum album, white hellebore; Narcissus poeticus, and jonquilla, narcissus and jonquil. The shore of Hieres is adorned by the Pancratium maritimum, sea daffodil, growing luxuriantly on the very beach. Allied to the bulbiferous, are the tuberous rooted plants, with sword-shaped leaves, several species of which are found in France. The most beautiful and worthy of notice, are Gladiolus communis, corn flag; abundant in the cultivated lands of the middle and southern provinces; the Iris Germanica, large purple fleur de lis, in Alsace and on the German frontier; and Iris petulans, and maritima, dwarf and sea fleur de lis, two elegant little plants, that are occasionally met with in Provence and Languedoc. Of the papilionaceous plants that are natives of this country, several deserve notice for their use or ornament. Lathyrus tuberosus, a vegetable of the pea kind, grows wild in Alsace, and is cultivated in many parts of France, for its large, succulent, tuberous roots; Lupinus varius, the great lupin, varying with blue, white, or flesh-coloured blossoms; and Cicere alpinum, chicke pes, are met with in the southern provinces, growing spontaneously, but are more frequently cultivated in large fields, as food both for cattle and man. In England, the former is considered merely as an ornamental plant, and is found in every flower garden. Trigonea sanum, frangipani, fenugreek, esteemed for its medicinal virtues; and Atragalus troagacantha, tragacanth vetch, so named from the gum it yields, are both natives of Provence and the vicinity of Montpellier. Many of our most ornamental shrubs belong to this class, such as Cytisus laburnum, great laburnum; C. nigricans, black cytisus; Colutea arborescens, bladder senia; Anagyrus fistida, stinking bean, trefoil; and Spartium juncu-s, Spanish broom.

Several succulent plants of the same natural class with the Sedum, are found on the dry rocks on the Spanish and Swiss frontiers, of which a few have been introduced into our gardens, viz. Sedum anacampseros, and villosum, ever-green arpine, and hairy sedum; Senecio cernuus, globiferum, and arachnoideum, hen and chicken sedum, and cobweb sedum. The class Pentandria of Linnaeus contains several well known plants that occur native in France, some of which have been introduced into our gardens and shrubbery; such as Primula villosa, and curvica, hair primrose, and auricula; Androsace maxima, and carnea, greater and flesh-coloured androsaces, all found wild on the mountains of Provence; Lonicera cornuta, blue-berried honeysuckle; Lycoctonum Europaeum, box thorn; Nerium oleander, rosebay oleander; Campanula grandiflora, and speculum, great-flowered campanula, and Venus' looking glass; Rhamnus palustris, and olaterum, Christ's thorn, and alaternus; Tamaria Gallica, and Germanica, German and French tamarisk. Others of this class deserve notice for their use in various arts, and in medicine, as Pistacchia terebinthus, the turpentine tree; P. lentiscus, mastic tree; Celtis australis, nettle tree; Rhamnus infectorius, the berries of which are used in dyeing, by the name of French berries, or grains d' Asignon; Anemone tinctoria, alkane, another dyeing drug; Rhus cotinus, and coria, common and Venetian sumach, the most powerful vegetable astringents, and largely applied to leather dressing and dyeing; Salsola soda, glasswort, a plant growing on the shore of the Mediterranean, from which the barilla of commerce is prepared. Some esculent...
plants also belong to this class, which, if not strictly native of France, have at least been long naturalized to the soil and climate; these are Ceratonia siliquea, carob-tree; Pistacia Vabronensis, pistachia nut tree; Rhhamnus zizyphus, jujube tree.

Decandria.

But few species of the French flora need be mentioned under this class Decandria. The fraxinella, Dictamnus albus; the yellow and harbore应当, Linnan flavum, and Narbonense; the sweet William, Deptford pink, and carnation, Dianthus barbatus, armeria, and eacheophyllum; the ferrugineous rhododendron, Il. ferrugineum; and the strawberry saxifrage, Saxifraga cadyi, are adopted into our flower gardens; the rue, ruta graveolens; and storax rue, Styrax officinalis, the former a native, the other naturalized at Hières, are used in medicine.

Polyandria and Icosandria.

Many of the most beautiful plants of the classes Polyandria and Icosandria, are to be met with wild in France: such are Chelidonium corniculatum, scarlet horned poppy; Papaver officinale, and tenuifolius, common and narrow leaved poppy; Ranunculus aconitifolius, mountain ranunculus; Adonis aestivalis, estivalis, and vernalis, pheasant eye; Thalictrum aquilegiolatum, feathered cumbine; Aquilegia alpina, mountain cumbine; Nigella damascena, and arenensis, fennel flower; Helleborus niger, and helenium, Christmas rose, and winter aconite; Anemone alpina, horntails and hepatica, alpine and scarlet anemone, and hepatica; Delphinium elatum, bee larkspur; Aconitum napellus, monkshood. Several trees and shrubs, both ornamental and useful, also arrange themselves under one or other of these classes. Myrtus communis, the broad leaved myrtle, grows with great luxuriance along the whole of the Mediterranean coast. Capparis spinosa, the caper bush; Cistus laurifolius, and Monspeliensis, the laurel-leaved and Montpellier cistus, three low shrubs of exquisite beauty, hang from the summits, or cluster round the sides, of the low rocks about Toulon and Montpellier. In the same vicinity also, are found Rosa gallica, the Provence rose; Meplius pyrecantha, the pyracantha; and Punica granatum, the pomegranate tree.

A few trees and shrubs remain to be mentioned, which will be more conveniently taken together than separated into their botanical classes. These are Quercus argiophora, and Cerris, the greater and less prickly-cupped oak, two very fine species that are found in plenty about Paris and Fontainebleau; Quercus cocci不容, Sibor, and Hix, the kermes oak, cork tree, and evergreen flax, growing chiefly in the southern provinces; Juniperus sabina, Oxycedrus, and Phanerocalc, the savine, the brown and yellow berried juniper; Osyris alba, poet’s cassia; Plethyrca latifolia, and angustifolia, broad and narrow leaved phillyrea; and Erica arborea, tree heath; all of them natives of Dauphiné, Provence, and Languedoc.

Among the rare plants which the Pyrenees afford, may be noticed the following: Ranunculus glacialis; R. parnassifolius; Androsace artica, (probably Carnea of Linnaeus); Daphne calycanthia; Saxifraga longifolia, and Arenaria fruticulosa. The plants found naturally growing on the best meadows in France are, exactly the same as those which grow in the best meadows of Great Britain, viz. Lathyrus pratensis; Achillea millefolium; Trifolium pratense; Trifolium repens; Plantago lanceolata; medicago lupulina, this is indigenous over the whole kingdom of France; Medicago Arabica polymorpha; Lotus corniculatus; Potentilla sanguiroba. These may be added another plant, found amply in the richest meadows in the south of France, and, what is remarkable, indigenous to England on poor land, the Cicorium intybus.

The botany of the singular desert of La Crau may be cursorily noticed; on it the Acanthium and Lavender grow, but so low and poor, so scarcely to be recognized. There are also the Centauru amuletrnata and solstitialis, and Eryngium. Where this desert is watered, however, clover, chicory, rib-grass, and avena eliator flourish.

III. The zoology of France, so far as it regards the domesticated animals, will be afterwards given; and on the other animals we must be very brief, confining ourselves, indeed, to the notice only of a very few. Bears are by no means uncommon in the vicinity of the Pyrenees, and Alps of Dauphiné. There are both sorts, carnivorous and vegetable eaters: the latter are more mischievous than the former, though not so dreadful, coming down in the night and eating the corn, particularly buck-wheat and maize; and they are so nice in choosing the sweetest ears of the latter, that they trample and spoil infinitely more than they eat. The carnivorous bears wage war against the cattle and sheep: they attack the former by leaping on their backs, when they force the head to the ground, and thrust their paws into the body in the violence of a dreadful hug. There are many hunting days every year for destroying them, several parishes joining for that purpose. A bear never ventures to attack a wolf; but several wolves together, when hungry, will attack and kill a bear. Wolves are very common in different parts of France, and very destructive to the sheep. The wild boar is also found in some parts of this kingdom. The ibex, rock-goat, or bouquetin (or bouquetin, from bouc, a goat, because they resemble goats), are found in the Pyrenees, and in the Alps of Dauphiné. They are of a grey colour, with very long and strong horns. On the mountains of Volini, near Bocheue, in the mountains of Dauphiné, the chamois is found, of the antelope class. The Bece-fico, and the Cecala, of the Italians, are not uncommon in the southern provinces of France. The Cecala never ceases making its peculiar and disagreeable noise, from sun-rise to sun-set. The noise it makes is said not to proceed from its throat, but from two membranous under the wings towards the tail, which it fills with wind, and blows like bellows. It is certain, if the animal be quiet, on touching the tail it immediately begins making its noise again. In this part of France, scorpions also are not uncommon. Of serpents there are 11 species found in France. Among the animals almost peculiar to this country, may be mentioned the Vesperilio serotina, Pipistrello, Barbastella, the Otis tetrax, the Charadrius lutes, &c.

CHAP. IV.

Agriculture of France.

Before the Revolution, agriculture in France was nearly in the same state in which it is still in almost
every country in continental Europe. About two-fifths of the land susceptible of cultivation, were in what is termed culture and pasturage, and produced, on an average, about one-half of what good culture, on the like quantity of the same soil, would have produced.

If France has been in any respect benefited by the Revolution—if she can claim any permanent and general good arising from it as a compensation and stone-

For the physical and moral evils she has suffered and inflicted—that benefit and good must be looked for in the state of her landed property, and in the condition of her agricultural population.

Before the Revolution, the land in France was held by various tenures, almost all of which were decidedly and extremely unfavourable to agriculture. The major rents of the clergy have been variously estimated. Condorcet, in his Life of Turgot, gives it as his opinion, that the clergy enjoyed near a fifth part of the property of the kingdom. Neckar calculated their revenue at 130,000,000 livres; but it is probable that their major rents may fairly be estimated to have amounted to about 120 millions of livres, or £4,500,000 sterling, exclusive of their tithes, which may be rated at about £3,600,000 sterling. The domains of the crown and of the princes of the blood, rented for about £1,200,000 sterling; the feudal and honorable dues paid to the nobility, with corvées, militia, &c. amounted at least to £5,000,000 sterling. Besides, the government drew from the produce of agriculture the sum of £8,000,000 sterling. In short, it has been calculated, that exclusive of the rents of land paid to the lay-proprietors, and of the duties of excise, consumption, and the like, the produce of the soil was charged annually with upwards of £21,000,000 sterling.

But agriculture laboured under disadvantages still more discouraging and oppressive, previously to the Revolution; to understand and estimate which, it will be proper to consider the different modes of occupying land which then existed, some of which, however, as we shall afterwards see, still remain. In the first place, there were the small properties of the peasants. These were to be found everywhere to a degree of which we have no conception in England, and which we should not have expected in the midst of the enormous possessions, and the oppressive privileges, of the nobility and the clergy. Even in those provinces where other tenures prevailed, they were to be found; but principally in Languedoc; Quercy, which now forms the department of Lot; the whole district of the Pyrenees, Bearn, Gascony, part of Guienne, Alsace, Flanders, and Lorraine. The condition of the peasant, who possessed these small properties, varied much in different parts of the kingdom. In Flanders, Alsace, on the Garonne, and more particularly in Bearn, they were in comfortable circumstances, and might rather be called farmers than cottagers; and in Lower Brit-

Money rent.

The second mode of possessing land, was by a money rent. This, before the Revolution, was the general practice in Picardy, Normandy, part of Flanders, Artois, Isle of France, and the Pays de Beauca. It also existed in some of the southern districts of France, particularly in Bearn, and about Navareens, a town in the department of the Lower Pyrenees. These

Feudal tenures were the third mode of occupying land. They abounded most in Brittany, Limosin, Berry, La Manche, &c. but they were scattered in a greater or less degree through the whole kingdom. These feudal tenures were fiefs granted by the seigneurs of the parishes, under a reservation of fines, quit rents, forfeitures, services, &c. As they formed the most oppressive evil under which agriculture laboured previously to the Revolution, and from which that event must certainly be allowed the merit of having freed it, it may be proper to notice some of them. Even to enumerate the whole of these oppressions would far exceed our limits; and indeed, the English language does not supply terms by which many of them can be expressed.

Among the more mild and tolerable of these feudal tenures, may be mentioned the obligation the tenant was under, of grinding his corn at the mills of the seigneur only; of pressing his grapes at his press only; of baking his bread in his oven. The peasantry in Brittany were obliged to beat the waters in marshy districts, to keep the frogs silent, in order that the lady of the seigneur, during her lying-in, might not be disturbed by their noise. In short, every petty oppression which could render the lives of the peasantry miserable, or interfere with the operations of agriculture, was authorised by these feudal tenures: though it must be confessed, that, before the Revolution, some of the seigneurs, convinced of their injustice as well as impolicy, forbore to exact them. Nor were the oppressions of the feudal tenures the only ones to which agriculture was exposed. There were numerous edicts for preserving the game, which prohibited weeding and hoeing, lest the young partridges should be disturbed; steeping seed, lest it should injure the game; manuring with night soil, lest the flavour of the partridges should be injured, by feeding on the corn so produced; mowing hay before a certain time, so late as to spoil many crops; and taking away the stubble, which would deprive the birds of shelter. These were oppressions, to which all the tenants of land, as well as those who held under feudal tenures, and even the proprietors of land, in many cases, were exposed. The latter, indeed, were dreadfully tormented by what were called the Capitaines, which, as affecting them in some measure, as the feudal tenures affected the farmers, may be noticed under this head. By this term was to be understood, the paramountship of certain districts, granted by the king to princes of the blood, by which they were put in possession of the property of all game, even on lands which did not belong to them, and even on manors granted long before to individuals; so that by this paramountship all manorial rights were annihilated. The privileges thus conferred, were most grievous and oppressive; for by game was understood, whole droves of wild boars, and herds of deer not confined, but wandering over the whole country to the destruction of the crops; and if any person presumed to kill them, he was liable to be sent to the galleys. It may easily be conceived, that the minute vexations, as well as the more prominent tyrannies, to which the feudal tenures gave rise, would occasion frequent disputes between the seigneur and his tenants; but the latter preferred submitting to them, rather than ap-
We may here also notice the *côvée*, as one of the taxes peculiarly oppressive and injurious to agriculture, though not confined to the tenure we are now considering. By the *côvée*, individuals were obliged to mend the roads by their personal labour; hence it is evident that this tax must have fallen exclusively on the poor; or if it was performed by those who kept labourers, it must have deprived them of the means of fully attending to their agricultural operations. This tax was not only impolitic, in so much as it placed the repair of the roads under the care of those who were totally destitute of the little skill requisite for such a task, but it was an easy engine of oppression; for, under the pretence that the work might be done without interruption, those who were liable to the *côvée* had it frequently allotted to them at some leagues from their habitations. Besides these *côvées*, which were an oppression to agriculture over the whole of France, there were the military *côvées*, which fell only on the villages lying in the route of the troops; the inhabitants of which were obliged to leave their occupation, however inconvenient and injurious it might be, and repair the roads along which the soldiers were to travel. Such are a few of the oppressions under which agriculture in France laboured, previously to the Revolution, arising either from the feudal tenures, or from the more general operation of the laws and measures of government, the privileges of the nobility and clergy, and the usages of the country.

The fourth mode of occupying land, resembled that which is common in Ireland, and which is there complained of as a great grievance, and as the source of much misery and oppression. Men possessed of some property, hired great tracts of land at a money rent, and relet it in small divisions to *metayers*, who paid half the produce. This mode of occupying land was most common in La Manche, Berry, Poitou, and Angoumois, but it was also met with in other provinces.

The last tenure was that of the *metayer*. These, who are a species of farmers that gradually succeeded to the slave cultivators of ancient times, and who, in Latin, are called coloni partarii, have been so long in disuse in England, that there is no English name for them. They may be generally described, as supplying the labour necessary to cultivate the land, while the proprietor furnished them with the seed, cattle, and instruments of husbandry, and, in short, the whole stock necessary for cultivating the farm. The common agreement was, that the produce should be equally divided between the proprietor and farmer, after setting aside what was necessary for keeping up the stock, which was restored to the proprietor, when the farmer either quitted, or was turned out of his farm.

Before the Revolution, seven-eighths of the lands in France were held under this tenure. It pervaded almost every part of Sologne, Berry, La Manche, Limosin, Anjou, Burgundy, Bourbonnois, Nivernois, Auvergne, &c. and was found in Brittany, Maine, Provence, and all the southern districts. In general, the half of the produce was paid to the proprietor; but in Champagne only a third. There were also other variations: in some parts, the proprietor paid half the cattle and seed, and the metayer the labour and implements, besides paying the taxes; the last, in other districts, were partly paid by the proprietor. In Normandy, a singular species of this tenure prevailed, viz. on the farms which the proprietors kept in their own hands.

It is scarcely necessary to point out the miserable state of agriculture, which must exist in a country where the system of metaying prevails. In the first place, it proves a lamentable deficiency of agricultural capital; and, in the second place, it has a manifest tendency to perpetuate this evil, and to keep the tenant in the lowest state of dependence, misery, and poverty. In some parts of France, the metayers were so poor, and consequently so dependent on their landlords, that they were almost every year obliged to borrow from them their bread, before the harvest came round.

Such were the tenures of land before the Revolution. Let us now enquire what effects that event has produced on them, and on the condition of the agricultural class in general.

In the first place, the number of small properties have been considerably increased in all parts of France. The national domains, which consisted of the confiscated estates of the church and emigrant nobility, were exposed to sale during the pecuniary distresses of the revolutionary government. For the accommodation of the lowest order of purchasers, they were divided into small portions, and five years were allowed for completing the payment. In consequence of this indulgence, and of the depreciation of assignats, the poorest classes of the peasantry were enabled to become proprietors, possessing from one to ten acres. They support themselves by cultivating these, and by labouring, at the same time, for the neighbouring farmers. The number of small properties has also increased from another cause, since the Revolution. Before that event, it seems to have been the law, or at least the invariable custom, in some parts of France, to divide the landed property among all the children. This local law, or custom, was extended, soon after the Revolution, to the whole kingdom; so that, by the present law of France, land, on the death of a proprietor, is divided, by the law itself, among his children. The deplorable consequences which must ultimately result from this division and subdivision of little properties, in a country like France, already so fully appropriated, need not be pointed out; they are sufficiently obvious. We content ourselves with stating the fact, as illustrating one mode in which the tenure of landed property has been affected by the Revolution.

In the second place, hiring at money rent is much more general since the Revolution; and if France continues quiet, and recovers from the injurious consequences of the Revolution, it may reasonably be expected that this species of tenure will become more and more prevalent.

In the third place, feudal tenures are done away, as well as tythes, game laws, *côvées*, &c. In some parts, however, the tenants, by their covenants with their landlords, are still bound to perform some services, but by the law, they must be entirely of an agricultural description.

In the fourth place, the two other species of tenure, that is, monopoly, where men of property hired great tracts of land at a money-rent, and relet it in small divisions, and the system of metaying, still exist, though not nearly to such an extent, nor in such an oppressive and ruinous form, as before the Revolution. Indeed, when we consider that these species of tenure were the unavoidable and necessary consequences of inadequate agricultural capital, we cannot expect that they should be abolished by the mere operation of law, or by the direct effects of any revolution, however wisely planned and carried into execution. If, however, we find that
they gradually die away, which seems to be the case, we may safely and rationally maintain, that the Revolution, besides the direct benefits which it has bestowed on agriculture, by the abolition of feudal tenures, and partial and oppressive taxes, has indirectly proved advantageous to this first of all arts, by placing in the hands of those who pursue it more adequate capital.

Such are the benefits which the Revolution has conferred on the agriculture of France, and which have manifested themselves, notwithstanding the military despotism which, after exhausting and weakening her for the purpose of enslaving the continent of Europe, has at length brought down upon her a just retribution for her too ready acquiescence in its schemes. These, however, are only partial and temporary evils; and we may confidently predict, that when they are passed away, the agriculture of France, which, from her excellent climate and easily worked soil, must always be the staple branch of her national industry, and the principal source from which she must draw her political influence and military power, will be found to have come out from the ordeal purified and refined, and the condition of her agricultural population in every respect greatly ameliorated.

It is not easy to ascertain the distribution of the land in France. According to Mr Young, there are arable lands only amounting to a capital sum of 5,000,000; in woods 19,850,000; in meadow and rich pasturage 4,000,000 acres; under lucerne, saffron, &c. 5,000,000; and the pastures and wastes occupy 27,150,000; thus making a total of 131,000,000 acres. This estimate, however, as far as respects the number of acres under wood, is certainly over-rated, though Mr Young on this point follows the authority of Mr Neckar; for a committee of the first National Assembly stated the whole extent of territory covered with wood at 18,100,691 ares, of 100 perches of 28 square French feet each; whereas, according to Mr Neckar and Mr Young, it amounted to 22,289,016 ares.

The general occupation of the land in the northern provinces of France, may be conceived, from the following account of the distribution of a small commune.

Woods and meadows in the occupation of the proprietor, 250 acres; two farms let, keeping two ploughs each, together eight horses, 500 acres; 10 Robert, having one plough, together 40 horses, 750 acres; 28 freeholders, keeping no horses, occupying 220 acres; in all, 1550 acres, of which 1300 were arable. These are distributed as follows: under fallow 433, under wheat 433, under oats 433. Those who have no ploughs pay 40 francs (33. 4d.) per acre to their neighbours for the team labour of the whole course, viz. four ploughings on the fallow, and one ploughing for oats; four loads of dung per acre carted on the fallow, and the harvest carting. Those proprietors who possess no ploughs are labourers, and in general work for the person who performs the ploughing of their land. The number of acres ploughed in this commune annually is 2165, or about 73 acres per day for 14 ploughs, leaving sufficient time for harrowing, harvest, and the carting of dung.

The rent of land is low in most parts of France. Before the Revolution, the rent of the arable and lucerne land was averaged by Mr Young at 15s. 7d. of the woods at 12s.; of the vineyards at £8. 10s. 6d.; of the meadows at £2. 9s. 9d. At present, extremely good land in Normandy may be got for 30s. per acre; 18s. and 20s. are more common. In other districts, it is even very much lower. The price of land of course is proportionally low. Before the Revolution, the average price of all the cultivated land in the kingdom, was estimated by Mr Young at £20 the English acre. In 1814, Mr Birkbeck mentions an estate near Cosme of 1000 acres arable, and 500 wood land, let on lease for nine years for £375 sterling, which might be bought for 22 years' purchase, or £833. It is proper to add, however, that one-third of the arable land of this farm was poor cold clay, of little value; two-thirds pretty good wheat land; part dry enough for turnips. In 1807, Mr Pinckney states, that the average rents from Paris to Maine were about 15s. the English acre; and the purchase from £15 to £18. The value of lands in the vine districts of France, is much higher, amounting on an average to upwards of £60 per acre, according to some authors; but others rate it only at £41 per acre. The size of farms is in general small; few, even in Normandy and the other provinces where agriculture is conducted on the best plan, and with the greatest capital and skill, reaching 300 acres. With respect to the capital employed by the farmers, Mr Young calculated it on an average of the whole kingdom, not to exceed 40s. per acre. In this, however, he was probably much mistaken. At any rate, at present, the average must be much higher. In French Flanders, it is calculated that a farm of about 250 English acres will require a capital of upwards of £1500 sterling, or about £54. 5s. per English acre. In this estimate, the live-stock is supposed to cost £7:16: 16: 8, of which 15 horses at £16: 13: 6; 4 each, 14 milch cows at £9 each, and 180 sheep at 7s. 8d. each, form the chief articles. The instruments of husbandry form the next division of this estimate, and amount to £198. Of these the large waggon is rated at upwards of £45; and the lighter waggon, of which there are three at nearly £20; four ploughs at £2, 10s. each, besides a Dutch plough at £2: 12: 6; the harrows, all of wood, at 8s. 4d. each. The third branch of the estimate is the servants' wages for 15 months. The number is eight; three ploughmen, one man to take care of the young horses, a shepherd, two women, and a swineherd; their wages, one with another, being £4: 11: 8 per annum each. The wages of the labourers are rated at from 8d. to 1s. per day. The maintenance of the 15 plough horses is calculated at about £150. It is probable that capital to the same amount is required in the other parts of France, where agriculture is well understood, and carried on with spirit and success. In the other districts, where it is far behind, of course the capital will be much less.

The prevailing opinion, that France is entirely an open country, is very erroneous. It is certainly much less inclosed than England. All Brittany, the western part of Normandy, and the northern part of that province as far as the Seine, most of Anjou and Maine, Lower Poitou, Touraine, Sologne, Berry, Limousin, the Bourbonnois, and a great part of Nivernois, part of Auvergne, and Quercy, are inclosed. The whole district of the Pyrenees is thickly inclosed. This district of country comprehends 11,000 square leagues; so that if the other parts of France that are inclosed be added, they will raise the total to a full half of the kingdom. But though so large a portion is inclosed, the inclosures in general are ill planned, and badly kept; and their value and utility so little understood, that the same rent is given for inclosed and open fields, provided both are arable. Perhaps the province of Bearn exhibits more attention to the proper management of inclosures than...
most other districts of France. There is not a county in England closer, thicker, or better inclosed; and, what is uncommon in France, the gates and stiles are in good order. Commons are not met with in France, at least not in the same sense in which they occur in England; but common fields abound, and they are cursed with all the mischievous consequences which attend them in England, such as rights of common pasture commencing on given days when under corn, and throughout the fallow year. There is a great deal of common field land in Picardy, Artois, part of Normandy, the Isle of France, Brie, the Pays de Beauce, and along the whole course of the Loire. In this last district, the farmers are in the practice of making an exchange with the poor, who have the right of common pasture. This they buy off, assigning an acre or more to every cottage in the parish.

It is a singular circumstance, that some of the poorest and least improved provinces, are precisely those which are best and most generally inclosed: hence it is easy to perceive, that the mere existence of inclosures is not in France, as in England, a proof of the advancing state of agriculture. The chief cause of new inclosures in France, is, that the communities in many parishes, in different parts of the kingdom, and more especially in the vicinity of the Pyrenees, being proprietors of the wastes, sell them to any person who applies for the property, in absolute assignment; in consequence of which, the purchaser has the power of inclosure: whereas, in the waste plains of Brittany, Anjou, Maine, and Guienne, the seigneurs are the sole and absolute proprietors, and they will not sell, but only feu their estates. Hence the waste lands remain unchanged and unimproved. The government of France, before the Revolution, took some measures to enforce or facilitate a general inclosure with respect to some of the provinces, more particularly with regard to Lorraine, in 1764 and 1765; but the popular objections and prejudices against inclosures, had such weight, that at the commencement of the Revolution, strong remonstrances were presented against them, and certainly the proportion of inclosed land has not considerably increased since that event.

The agricultural implements in general use in France are very rude and imperfect in principle as well as in construction; the plough in most parts is almost entirely of wood, and scratches and pushes forward the soil, instead of penetrating to any deptli, or turning it over. In the vicinity of the Pyrenees, a light imperfect plough, similar to what the Romans used, and drawn by a pair of weak cows, is not uncommon. In the neighbourhood of Toulouse, a better plough is seen, of pretty good construction, to which two strong oxen are yoked, the ploughman driving them by means of a long staff, that answers the double purpose of a goad and a paddle. The use of oxen in the plough is pretty general in France, and they are yoked in a different manner from what is practised in England: A piece of wood, of about 1-6th of the weight of an English yoke, is put across the forehead of the cattle, the extremities of which are neatly hollowed out, so as to fit the mould of the head, and the hollows lined with a piece of woolly sheep skin, to answer the purpose of a soft pad or cushion. This light and easy yoke is braced to the horns with a small thong of leather, to the middle of which the beam of the plough is attached: the animals are thus completely equipped for their labour. It seldom happens that more than two oxen are yoked in a plough. In the north of France, as well as in some of the eastern, western, and middle provinces, horses are more commonly used than oxen; generally two horses, but in some instances three. Besides the plough that is used for the general purposes of agriculture, in several districts, both in the north and south of the kingdom, a little plough called a binot is employed, principally for the purposes of plowing and destroying the weeds. In some respects the binot resembles a plough, with a double or sculfer share, and two mould boards, but it has no coulter. In the French Netherlands, where agriculture is carried on in a regular and systematic manner, some farmers have three binots to eight ploughs, some two binots to five ploughs, and some two to four ploughs. Only one ploughman and two horses are employed; the furrow which it makes is from five to six inches in depth. Its operation is different from that of the common plough, since it does not turn over the land, but elevates it into small ridges, by which means the weeds are exposed to the action of the frost and of the dry weather. After the binot, the land is always ploughed for the seed furrows. The harrows, in general use, are equally imperfect in principle and construction with the ploughs, and have always wooden teeth. In most parts of France rollers are unknown, and their use is supplied by a plank on which a boy rides over the land. Their carts and wagons display equal ignorance of mechanical principles, being in general of enormous length; the carts which are used for the carriage of goods, are not above two-thirds so wide, and certainly two-thirds longer than those in England; they travel in large companies, frequently 15, 18, or 20, in a string together, especially in the south-east of France, each drawn by a single horse, with about half a dozen drivers attending them. The charette, or cart in common use, consists principally of two parts—the carriage and the body; the carriage part is very simple, being composed of two long shafts of wood, about 20 feet in length, connected together by cross bars, so as to form the bed; on this the boards are laid, as occasion may require: in the same manner, the sides, a front and back may be added at pleasure. The axle and wheels are in the usual place and form. The movable body is fixed on this carriage; it consists of a similar frame work, of two shafts, connected by cross bars. This body moves upon an axle-tree, and extending some feet beyond the carriage behind, it is let down with ease to recover its load, while the body, moving on a pivot, or axle, is easily purchased up from before.

In France, before the Revolution, and even since that event, the construction and repair of the roads is entirely lodged with the government. The great military roads, especially that over the Simplon, are excellent, with respect to the principle on which they are constructed, the materials of which they are formed, and the whole of their execution. But the roads which were not necessary for military purposes have in many places been greatly neglected, although it was stated, in the year 1806, by the minister of finance, that more than thirty millions of francs were annually requisite for the repairation of the roads and public works. In 1809, a collection of laws was printed regulating the management of the roads; in which a law passed in the time of the Republic, for establishing the use of broad cylindrical wheels, is strengthened enforced. According to this law, the wheels of heavy wagons were to be nine inches three lines broad; and they are allowed to carry only a certain weight, which varies during the five winter and seven summer months. It was also enacted, that in those parts of the kingdom where the roads were paved, the passage upon the pavement should be suspended during those seasons when they
were likely to be injured, and the side roads alone should be used. The weight allowed to be carried was not only to vary in winter and summer, but also according to the form of the wheels; and, in order to enforce this law, weighing engines were to be erected, and the owners of carriages exceeding the legal weights were declared liable to severe fines. But these laws have been very partially enforced; so that some of the best roads in France, under the old government, have fallen into complete disrepair. This has been very particularly the case with the famous Chausée of Languedoc, which begins at Villeneuve, whence it crosses the whole province. The cross roads have suffered still more than the main roads since the Revolution; and both have suffered more in the Atlantic departments, than in any other districts of France. Throughout the whole department of Finisterre, the cross roads are in a most wretched state. The roads, in several respects, differ from the roads in England; they are generally broad, always straight, paved, and planted on both sides with chestnut trees, poplars, walnut, mulberry, and other fruit trees. There are 28 principal roads from Paris to the boundaries of the kingdom. Turnpike gates and tolls have been established since the Revolution, at the distance of five kilometers from each other.

The state of agriculture in any country may generally be pretty well ascertained, from the rotation of crops which is pursued: If these are conducted on good principles the agriculture can scarcely be very bad; on the contrary, if bad rotations are pursued, agriculture has made very trifling advances towards perfection. If we judge of France according to this rule, we shall decide, that, though over by far the greatest part of the kingdom agriculture is in a miserable state, yet in some parts it is well understood and flourishing.

We have already mentioned the divisions of France into districts, according to the nature of the soil; we shall now note the principal rotations pursued in each district. In the district of rich loam, two rotations principally prevail, according to one of which, in Flanders and part of Artois, there is no fallow, but a constant succession of crops. The second rotation, the common course is fallow, wheat, or rye, and barley or oats. In the district of chalk, the rotation is in general very bad. In the province of Sologne it is fallow and rye: certainly the very worst and most unprofitable that can be practised on any land. In the district of gravel, especially in the Bourbonsnois and Nivernois, the same wretched rotation is pursued. The district of various loams is chiefly distinguished by the introduction of turnips into the rotation; but, as we shall afterwards have occasion to remark, the culture of this valuable root is ill understood in France.

The rotation in the stony district is particularly distinguished, by the introduction of potatoes in some parts of it, as a preparation for wheat. Where this root is not cultivated on a large scale, and as a crop in regular rotation, the common course is fallow, wheat, or rye, and barley or oats. In the district of chalk the rotation is in general very bad. In the province of Sologne it is fallow and rye: certainly the very worst and most unprofitable that can be practised on any land. In the district of gravel, especially in the Bourbonsnois and Nivernois, the same wretched rotation is pursued. The district of various loams is chiefly distinguished by the introduction of turnips into the rotation; but, as we shall afterwards have occasion to remark, the culture of this valuable root is ill understood in France.

From this account of the most common rotations in various parts of France, it will be seen, that in general they are conducted on very erroneous principles; and that, even where they are good, the climate ought to have the merit rather than the skill of the agriculturist. In the south of France, the climate enables him to take two crops in the season. This advantage is, however, also derived in French Flanders, entirely through the attention and skill of the farmer. The second crop in that district being carrots, turnips, spurry, and yellow clover.

The following, perhaps, will give a sufficiently precise and clear view of the general rotations practised in France. The arable land, that comprises nearly the whole of the kingdom, with the exception of the
FRANCE.

vinyards, and a few tracts of mountain, may be divided into five classes, with respect to fertility of soil. The first class bears a crop every year, as in most parts of French Flanders, some parts of Normandy, the Limagne of Auvergne, the neighbourhood of Toulouse, and generally where maize is cultivated, or irrigation employed. The second class, which is rather inferior in point of soil, but is still good land, is cultivated with the intervention of a fallow once in six years, as about Dieppe and Rouen particularly; once in five years, as in some parts of French Flanders, and in a few other districts. The third class of land, of middling quality, which embraces a large portion of the kingdom, is managed on the old plan, of fallow, wheat, oats, or barley. The fourth, still poorer land, is fallow and wheat alternately; and the last class of land, where the soil is in general miserably poor, is cultivated in the round of fallow, rye, rest without grass seeds. As it is probable that the three last classes of soil comprise half the cultivated surface, and as half of them are fallow, it appears that one-fourth of the whole country is lying in a state entirely unproductive. The best husbandry in France, then, is in the south and in the north; in the former, the goodness of the climate enables the agriculturist to raise maize and wheat alternately, and to have second crops of millet, clover, lupins, &c.; and in the north, the skill of the agriculturist has, in a great measure, banished fallow. On the whole, so far as respects rotation of crops, French agriculture cannot be much praised; and it will be seen, that the management of the principal crops is in general not better conducted than the rotation. Before, however, we proceed to notice the culture of particular crops, it is proper to mention, that the application of land to the crops best suited to it is not well understood. Even in many parts of Normandy, land that would bear heavy crops of wheat is not unfrequently sown with barley; and rye in many parts is sown, where the soil is admirably adapted for wheat. It not unfrequently happens, too, that rye is sown along with wheat; the consequence of which is, that, as the former ripens three weeks or a month sooner than the wheat, when the latter is reaped, almost the whole of the former is shed and lost.

Different kinds of wheat are grown in France; the principal of which are the bearded wheat, various species of the common winter wheat, and spring wheat. What in England is called hedge wheat, which is of comparatively late introduction, has been long known in the north of France, particularly at Calais, Lisle, and Dunkirk; it is known there by the name of pullet wheat (blé pullet), or white wheat (blanc blé), and it is regarded as wheat of the first quality. One of the best kinds of spring or summer wheat known in France, is called blé tremois,—the real summer wheat, triticum aestivum,—it is sown with success so late as the end of May, and yields a large increase. The straw, too, is excellent fodder. The produce of wheat in France per acre is small: Even in the best cultivated districts, and on the best soil, it cannot be averaged at more than 18 or 20 bushels per English acre. In most places it is reaped; this operation being performed, like the other agricultural operations in France, chiefly by women. In other districts, however, it is mown: the whole process of harvesting is very carelessly performed. At a good year, in Picardy, 40 sheaves are calculated to produce a septime of wheat of 240 lb. The principal wheat districts of France, are French Flanders, Artois, Picardy, parts of Normandy, the Limagne of Auvergne, part of Alsace, &c. Beauce, a province which lies between the Isle of France, Blosisoi, and Orléanais, and which now forms the department of the Eure and Loire, is so extremely fertile of wheat as to be called the Granary of Paris. The wheat of Narbonne is in high repute for seed.

Barley is not extensively or judiciously cultivated in barley. France. There are two sorts: the one which the French call square barley, or barley of autumn, because they sow it in that season; the other is called spring barley: This is the common sort sown in France; they begin to sow it towards the end of April. This grain is the common food in many parts; either made into bread by itself, or mixed with wheat flour. It is also made into peeled barley: the best peeled barley comes from Vitry-le-François, a considerable town in the department of Marne. Good peeled barley is also made at Charenton, near Paris. Respecting the culture of oats there is nothing that calls for notice. Rye, as it may Rye, have been observed from the rotations which have been specified, is very generally cultivated, principally for its grain, but in some places as green food. In the latter way, the ridges of the wheat stubble are split down, as early as possible after the crop is off the ground, and rye is sown, which in April or May is cut for the cattle; and, if the weather proves favourable, in some parts of France it is mown three times. The rye in France is very liable to a disease called ergot, which seems to be unknown here; and which produces, in those who eat the grain so affected, the most dreadful complaints. The average produce of rye, when reaped, is very small, perhaps not more than 15 or 16 bushels the English acre.

The annual produce of wheat, rye, barley, and oats, which may be considered as the chief arable products of France, has been differently estimated; and, indeed, only an approximation to the truth can be looked for on this account. According to Vauban, in his time, the annual produce of these grains was 69,175,000 septiers of 12 Paris bushels, or 240 pounds weight. According to Quesnay, the father of the sect of the economists, it was 45,000,000 septiers. In the former, Abbé d'Expyll, 78,472,380. Lavoisier calculated it at 50,000,000 septiers; and Mr. Arthur Young at 75,000,000. The variations here are very considerable; but if we take the average of all these sums, it will give 61,519,672 septiers, as the annual produce of wheat, barley, oats, and rye, in France. The proportions of these different grains, it is not easy even to conjecture with any probability of approaching the truth. Rye and wheat are certainly produced in by far the greatest proportions; perhaps, in pretty nearly equal proportions. Barley and oats are cultivated on a very small scale; the latter, especially in the south, from the two great heat of the climate, are not so much grown as in the north, and where grown, are in general unproductive.

Beans, such as we cultivate in England, are principally grown in French Flanders; besides these, the French grow what they call fèves de marais, or beans of the marsh, which they eat only when green and fresh. They also dry them, but in that state, they serve only as food for cattle. Some persons eat them in Lent, buying them green, and peeling the skin off; they split them in two, and dry them in the open air. Haricots or kidney beans are pretty generally cultivated as a fallow crop; they are carefully hoed, and are very productive.

The limits of the maize district have already been noticed, in treating of the climate of France; and the importance of this grain in an agricultural point of view, has also been sufficiently pointed out, in the ac-
count of the rotations pursued in the south of the kingdom. It is planted in rows or squares, so far asunder that all necessary tillage may be given between them. A considerable part of the summer it affords, as it were, a rich meadow, the leaves being stripped regularly for oxen, affording a succulent and most fattening food, which accounts for the high order of all the cattle in the south of France. The meal of maize, besides being used extensively as food for man, is also employed for fattening oxen, hogs, and poultry. Thus it appears that this most valuable grain is a meadow to feed the cattle in summer, and nourishing food to fatten them in winter. In some parts of France, it is sown broadcast and thick, for the purpose of mowing to suit cattle. This practice is pursued in the northern districts, where the climate is not sufficiently warm to ripen it; and even in the southern districts it is not uncommon to sow it as an after crop, in the same manner, and for the same purpose. Near Roussillon, it is sown in May, to be cut green in August, at which time more is generally in progress, to be applied to the same purpose in December. In the north, it is sown in the beginning of May, on well dunged fallow, and cut when beginning to come into ear. An arpent will maintain four cows from June to September; and the wheat that succeeds is always good. Although maize is undoubtedly an exhausting crop, yet in the Pays de Basques, on the low and humid lands of that province, it is cultivated for three years successively without manure; and this mode of farming, which is particularly mentioned by M. Parmentier in his Mémoire sur le Maïs, is even recommended as good by that author.

As maize, where intended to stand for harvest, is always planted in rows, little seed is required; in general, only the eighth part of the seed which would be necessary if wheat were sown; and the arpent yields more than double of that grain. In some very fertile and well managed spots, an arpent has yielded 9400 pounds. It is commonly ripe in the month of September; and even when later, the grain is protected from the inclemency of the season, by its broad and strong leaves. It is usual, in most parts of France, to spread it under the roofs of the cottages to dry; the eaves of the houses being made to project 10 or 12 feet from the plane of the walls for this purpose. When the corn is cut, it is tied up in bunches, and suspended from light rafters, horizontally placed under the shelter of these eaves.

Buck wheat. Buck wheat is cultivated to considerable extent, particularly on the poorer soils; and being of rapid growth, sufficient time is allowed to clean the land, before the succeeding crop of wheat or rye is sown. It is much used as food for man; and, in some parts, as has been already noticed, as green food for cattle: in this case, it is a stubble crop.

Turnips. Before the Revolution, considerable exertions were made by the intendants of the several provinces, to introduce the regular and general culture of turnips. They distributed seed, and published small treatises on the proper management, and great advantages of this root; but their exertions seem to have been in a great measure unsuccessful; for turnips are very little cultivated in any part of France. Mr Birbeck, who travelled in 1814 from Dieppe through Paris and Lyons to the Pyrenees, and back by the route of Toulouse, says, he did not see a single acre of turnips, or even of rape, in his whole journey. That they are not grown in the south of France, he ascribes to the extreme dryness of the climate. This undoubtedly would render them a very precarious crop; but when he assigns the severity of the winter in the northern districts of France, as the cause of their not being cultivated there, his reason does not seem equally good. In fact, they are cultivated in French Flanders, in Alsace, Lorraine, and in other districts in the north and east; and it appears from Mr Young's Tour, in 1787, 1788, 1789, that at that period they were not entirely unknown even in the middle and southern districts. In the department of the Lot, rape, that is a kind of turnips with a carrot root, long, thin, and poor, are cultivated; these are also grown near Caen in Normandy, in the road to Bayeux; and in Bresse, or the department of the Ain, where they are known under the denomination of navets. Between St Palais and Bayonne, many turnips are grown in a singular husbandry; the stable is either burnt by itself, or where it has not been left long enough, straw is spread over it, and then it is set on fire. The ground thus cleaned of weeds, as well as manured, is then sown with turnips. On the whole, however, the culture of this valuable root is very partially known in France; and where known, is miserably conducted, as no hoeing is ever given to it.

Potatoes have not been long cultivated, even as a garden crop, in France, and as a field crop to any extent, or under good management, they are yet comparatively little known. The Lyonnais was one of the first districts in France where they were cultivated. At their introduction, they were called white truffles, from the root resembling the truffle in form, and from their being dry, like a truffle, out of the ground. It is computed, that since this valuable root was brought into general use in the Lyonnais, the consumption of corn has been lessened one-third; the inhabitants give them to their cattle and poultry, and the poultry of this district is highly celebrated. Soon after M. Tarjot was appointed to his generalcy the cultivation of potatoes. The people at first regarded this root with apprehension, or disdain, as beneath the dignity of the human species; and they were not reconciled to it, till the intendant had caused it to be served at his own table, and to the first class of citizens, and had introduced it among the fashionable and rich. At present, a vast quantity of potatoes, of a tolerable good quality, are grown in the provinces of Poitou, Normandy, Limosin, Gatinois, and the Isle of France, as well as in other districts.

Cabbages are cultivated in French Flanders, Alsace, and a few other districts. In the neighbourhood of Strasburg particularly, this plant is cultivated on a very extensive scale, but almost entirely for the consumption of Holland and Ments, to which places it is calculated that cabbages to the value of above 30,000 crowns are sent annually. In French Flanders, the Brassica arvensis of Linnaeus, there called Colza, is cultivated in astonishing quantities by the farmers. There are two kinds of colza, one called white colza, because the leaves of the flower are white; the other, cold colza, the leaves of which are larger and thicker. It has this name, because it supports better the rigours of winter. This plant is cultivated in a very rich soil. There are two modes of sowing it; either in a nursery to be transplanted, or in the usual mode. The white colza requires less manure than the cold colza. The seed is commonly ripe about the end of June or July. The plant is cut with a sickle, having a sharp edge. Colza intended solely for winter food, is sown in June in a field prepared for the purpose; it is cut, and
FRANCE.

Statistics.

The case, however, is very different with respect to lucerne and sainfoin. The culture of the former is one of the principal features of French husbandry. It is the medio of the ancients, so called because it came originally from Media, and spreading through Persia, it became at length known to the Greeks, who cultivated it assiduously, and recommended it highly. From Greece it was transferred to Italy, and before the time of Cato or Virgil, it was in the highest credit with the Romans. It flourished with them as long as their empire flourished. Before the destruction of the empire, it seems to have been carried into Spain; or perhaps it was introduced there by the Moors, with whom, during their abode in that country, it was in high esteem. When the arts revived, it returned again into Italy, and was assiduously cultivated in that country, especially in the kingdom of Naples; thence it advanced into the southern part of France; and from the place where it was first or principally cultivated, it was called grand trefle, trefle, or foin de Bourgogne. The era of its introduction into France is not accurately known; but as it passed from that country into the Palatinate, upwards of 250 years ago, it of course must have been longer cultivated in France. It is now grown in Picardy, Isle of France, Roussillon, Languedoc, Gascony, Poitou, Touraine, Artois, Normandy, Dauphiny, and Provence, to a great extent, and partially in other districts of the kingdom. It is invariably sown broadcast, and generally without corn, though sometimes with oats. It is cut for the first time, in the southern districts, about the end of April; in the northern districts of course later. Where irrigation is practised, it is watered every 40 days after the first cutting, to the extent of five cuttings in all. If the land be not watered, it is cut thrice with a full product, where the soil and climate are favourable, and the management good. The watering, however, brings it to maturity; or rather decay comparatively quickly, since in this case its duration is not above seven or eight years, but on other lands twelve, sixteen, twenty, and even thirty years. In some parts of Roussillon, they take three crops of wheat after lucerne. This crop is apt to get weedy. In which case, in some of the southern districts, it is cleansed by means of ploughing it in the winter with a narrow pointed share, during frosty weather. This operation, performed at this season, kills the weeds, but does not injure the lucerne. Where the land is not very rich, or where it is not intended to crop it severely, the practice of sowing wheat after it, is not pursued; but barley and oats cut green, or made into hay, and not suffered to ripen, are taken. By this management, the roots of the lucerne, which are not easily or soon eradicated, and which would prove injurious to crops of corn, are turned to advantage; the shoots from them mixing with the forage of the barley or oats. The produce of such a course varies considerably in weight. In the neighbourhood of Lianscourt, where it is well managed, three cuttings will yield 1600 bottles of hay, each of 12 lb. or 19,200 lb., which is above seven tons the English acre. In general, the crop may be estimated at 12,000 lb. or rather more than five tons the English acre. The hay made from the two first cuttings, is generally given to horses. The hay from the three cuttings to cows. We have been thus particular in our account of the lucerne husbandry of France, since, as we have already remarked, it forms one of its best and most distinguishing features.

Sainfoin is not nearly so generally cultivated, and sainfoin, certainly by no means so well managed, nor so valuable a crop, either in its actual produce, or as a preparation

Rape is extensively cultivated in French Flanders, Artois, &c. but not in the other districts of the kingdom. The plants are raised on a small quantity of ground, that has been fallowed, well dunged, and worked repeatedly by the binotor plough. Rape is afterwards transplanted into a field, that had formerly produced winter barley, or winter wheat. The young plants are put into the ground, either by the dibble, or by the plough. Rape is grown either as green food for sheep, or for the sake of the oil. The latter is the more common, as well as the more profitable. In a small circle round Lisle, there are 450 windmills for extracting oil from the seeds produced in that neighbourhood. In the year 1810, the produce was estimated as follows: 1st, 180,000 picolitres of oil, at 10 francs each, in English money £617,550; 2nd, The cakes valued at one-sixth part, £196,260; the total value of the produce £553,840. The crops of wheat after rape in French Flanders, are reckoned to be better than those that are grown after fallow. Poppies are also cultivated in the northern districts of France for their oil.

Spurny.

In the same district of France, where indeed the most spirited and successful agriculture is carried on, spurry (Spergula arvensis) is cultivated. After the crops have been reaped, the grain is slightly ploughed and sown with it. In October, the cows are tethered on it. The butter from the milk thus obtained, is called spurgula butter, and it is employed for the use of the kitchen, as being both cheaper and more profitable than any other for that purpose.

Parsnips.

In some parts of Brittany, parsnips are cultivated. The seed is sown in February or March, and the parsnips are raised out of the ground in October or November. They are chiefly employed in fattening cattle and hogs. Lupins (principally Lupinus albus) are grown very extensively in the southern districts, either on the wheat stubbles, as winter food for their flocks; or for the sake of the seed, which is eaten by the inhabitants. Of all the species of clover, trefoil, or yellow clover, is most abundant, especially in the south. It is generally sown as forage on the wheat stubbles. In the district of the Pyrenees, these are ploughed in the beginning of August, and the clover seed is harrowed, or rather rubbed in by means of a piece of wood fixed to the plough. This clover produces much luxuriant and valuable food for sheep and lambs early in the spring; after which it is watered, and produces by the end of May a full crop of hay; it is then ploughed up, and haricots, maize, or millet planted, either of which is off in time for putting in wheat. The other kinds of clover, till very late, were scarcely met with anywhere except in French Flanders; but within these very few years, what the French call Praires artificielles, which were less properly artificial grasses, have been introduced into several districts. Still these and turnips, the two grand distinguishing features of good husbandry in Great Britain, are comparatively little known or valued in France.
for other crops, as lucerne is. In England, sainfoin generally lasts from eight to twelve years. In France, it seldom lasts more than four or five years. It is usually sown with a second or third crop of corn; and, in some places, the farmers do not think of this grass till their lands are so full of weeds, and so exhausted, that they will produce corn no longer. This management, and the circumstance that their leases are generally short, seldom extending beyond nine years, sufficiently accounts for this crop not being kept in the ground so long as it is in England; for certainly with respect to soil, France is peculiarly favourable for this crop; and yet in some of the districts where it might be introduced with great advantage and profit, it is not grown. The culture of tobacco was formerly prohibited in France, except in certain parts: as Pont de l'Arche; Normandy; Vertus, in the department of the Marne; Picardy; Mont Aube; Tonnung, a small town in the department of the Lot and Garonne; Clerac, another town in the same department. Hainault, Artois, and Franche Comté, were similarly privileged; but the soil of these provinces was decidedly hostile to the cultivation of the tobacco plant. At present, it is principally cultivated in Alsace. The average produce of France is estimated at twelve million pounds annually; but the quality is not good.

It has already incidentally appeared, that millet is cultivated to a considerable extent in the southern districts of France. In some parts of Gascony, it is sown on three feet ridges, with three irregular rows on each ridge, and carefully hoed. In other parts, it is sown ridge for ridge in the same fields with rye. In order to free the millet from its chaff, the French pound it in a wooden mortar, or pass it between millstones, which they keep sufficiently asunder, to prevent the grain being crushed. In the southern parts of France, especially in the vicinity of Bourdeaux, they prepare from the winnowed millet seed boiled in milk, a very favourite mess, not unlike rice milk; they also make the seed into cakes, pastry, &c. Millet is a grain, that thrives well under irrigation, which is liberally bestowed upon it in the district of the Pyrenees.

Carraway grows plentifully in France, and is sent particularly from Languedoc and Provence in large quantities to Paris, where there is a vast consumption for it among the druggists, apothecaries, confectioners, distillers, &c. Flax is cultivated largely in many parts of France, particularly in certain districts: viz. the French Flanders, Alsace, in La Maine, Anjou, Languedoc, Brittany, and Normandy. It is also found in the garden, or small farm of every peasant, for domestic use. The flax husbandry is carried to the greatest perfection in the vicinity of Lisle, where it is raised every six years without injuring the soil. Land that has carried a crop of wheat or oats after clover, is preferred. Repeated ploughings, harrowings, and plenty of rape cake or night soil, are given. In every part of France where flax is cultivated a good crop, that is, flax of fine quality, is preferred to a large and coarse crop; hence perhaps they obtain the fine stapled flax, of which their Cambresis and lawns are made. Hemp is cultivated in Flanders, Picardy, in the territories of Rennes, St Malo and Dol in Brittany, where the hemp fields occupy a very large space; in Upper Languedoc, and in Auvergne, where the soil is peculiarly adapted to its culture. But perhaps of all the provinces of France, Alsace, especially part of what is called the plain of Alsace, is most deservedly famous for the culture of hemp. It is also grown like flax in the gardens, &c. of the peasants, for their domestic use. Neither hemp nor flax is cultivated in sufficient abundance for home consumption. Previously to the Revolution, the naval consumption alone of hemp was 400 millions of pounds, more than one-third of which was imported.

Many plants used in dyeing are cultivated extensively in France. Madder is grown in the vicinity of Avignon, and in other parts of the south, but to a much greater extent in Alsace. Into this province it was introduced during the reign of the Emperor Charles V. and by the exertions of that sovereign himself; but the cultivation of it was not of much consequence till about sixty years ago, since which time the growers and makers of it have been able to rival the Dutch in supplying the manufactures of France. This extended cultivation was principally the effect of a decree of council in 1756, which promised privileges and exemptions to those who, in clearing marshes, should plant them with madder; for though it was soon found, that this plant will not thrive nearly so well on marshy land as on a dry and kindly soil, yet this measure of the French government directed the attention of the farmers of Alsace and other districts to this plant. Before the Revolution, it was calculated that 3000 acres were under madder in the department of the Lower Rhine, and principally in the vicinity of Hagganen. The Revolution was injurious to its cultivation; for, in 1796, 7, 8, and 9, there were only 80,000 to 700 acres in cultivation; in 1800, the plantations had increased to 850 acres; and, since that time, the culture has extended, though it has not nearly reached what it was before the Revolution. An acre produces, in common years, 12 or 15 cwt. of dry madder. The crop of 1778 was uncommonly abundant, being 50,000 cwt.; in 1780, 34,000 cwt. was produced; in 1798, only 8000 cwt.; in 1799, 10,000 cwt.; at present, about 15,000 cwt.

After much trouble and repeated trials, the manufacturers of madder in Alsace succeeded in rendering it nearly equal in quality to that of Zealand; and it is said, that Germany and Switzerland prefer it for their red dyes. On account of the smallness of the crops, the whole produce is consumed within the year by the circumjacent manufacturers, except a small quantity that is exported to Switzerland and Germany; but from 1776 to 1796, when Lower Alsace produced annually from 40,000 to 50,000 cwt., about one half was used in the remainder went to England, Germany, Switzerland, and even Italy; in the city of Genoa, Milan, and Leghorn, being supplied from Hagganen. There are nine factories or manufactures of madder in the department of the Lower Rhine, besides which there are five madder mills, and about eighty dyeing houses.

Wool is very common in many of the French provinces, particularly in the environs of Paris; and in Normandy, especially about Rouen. It is usually sown in the fields after haricots, hoed frequently, and dried carefully after cutting.

Languedoc has long been famous for its cultivation of wool: the best grows in Upper Languedoc, particularly in the diocese of Alby. What we style a boll, they call cocagne; and such a source of wealth was this plant in former times, that 'paix de cocagne' is still a French phrase for a country of abundance. This arose, not merely from the great quantity of wool sold, but from its leaving the soil in an excellent state for grain, in consequence of the extraordinary culture which it required. At that period, it was the great staple of
FRANCE.

Languedoc: but, by the decrease of the demand for it at home and abroad, the culture of it has comparatively declined, and given place to that of millet. In Languedoc five crops are gathered in one year. Great care is taken both in the cultivation, and in the subsequent preparation of them. When the ears become dry, they are gathered and carried directly to a mill, much resembling the oil or tan-mills, and ground into a smooth paste. This is laid in heaps, pressed close and smooth, and the blackish crusts, which forms on the outside, reunited, if it should happen to crack. In this state it lies for fifteen days, when the heaps are opened, the crust rubbed and mixed with the inside, and the matter formed into oval balls, which are pressed close and solid in wooden moulds. These are dried upon hurdles; they turn black on the outside if exposed to the sun; if in a close place, yellowish, especially if the weather be rainy. The dealers prefer the first. The good balls are distinguished by their being weighty, of an agreeable smell, and of a violet colour within when they are rubbed.

Ochilla weed can scarcely be said to be cultivated: it however grows in abundance, and of a good quality, in Auvergne. There is also in this province a kind of moss different from the real ochilla, known by the name of orseille de terre, orseille d'Auvergne, which is used for dyeing, but it contains fewer and lighter colouring particles. The real ochilla is prepared in France, for the purpose of dyeing, by being ground with the stones, moistened occasionally with spirits of wine, and so made up in a paste, which they call orseille en pâte. French berries, that is, the berries of the Rhumus infectiorius, are grown abundantly in the south of France, particularly in the vicinity of Avignon, whence they are called graines d'Avignon. They are used considerably in the south and middle of France, to give a yellow dye, chiefly for silk. They are gathered unripe, bruised, steeped, and then boiled in water mixed with the ashes of vine stalks, to give a body, and then passed through fine linen. The colour they give is fine, but very evanescent, especially when exposed to the sun.

Saffron is cultivated about Toulouse, Angouleme, in the principality of Orange, near Avignon, in Normandy, Angoumois, and Gatinois. The best saffron in France comes from Boinne in Gatinois, where the soil is a mere sand. The saffron of Angoumois is perhaps next in quality, and is grown there in great abundance. This plant seems to have been introduced into Spain by the Moors, and from Spain into France. The roots are liable to many maladies in France, which are unknown here. There is nothing peculiar in the mode of culture, except that sometimes, in the very height of the season, they pull the flowers in the evening as well as in the morning, instead of only in the morning, as is practised in England. Turned, a valuable dyeing drug, is prepared chiefly in the village of Grand Garlague, near Montpellier, from the croton tinctorius, which the French call marille. The flowering tops, in the latter end of July or beginning of August, are prepared by a long process, and linen or woollen rags dipped in their juice. These are packed and sold under the name of tournois en drapèrons. These shreds are chiefly used for tinging wines, cheese, linen, and paper.

Sumach is cultivated in the neighbourhood of Montpellier, where it is called rédout, or rondou. Its shoots are cut down every year quite to the root, and, after they are dried, they are reduced to powder in a mill. Horehound is another plant used in France for dyeing.

To it the French manufacturers are chiefly indebted for the deep black colour of their cloths.

But our limits will not allow us to enumerate all the plants raised or used in France for the purposes of dyeing; and we must also omit the medicinal plants, of which there are not a few in the southern districts, as well as the aromatic plants, which grow in great abundance all round Montpellier, and furnish those perfumes for which this place is famous. We may, however, just mention, that in the vicinity of Montpellier the capillaire (maiden's hair) is particularly abundant, and the syrup made from it is in high reputation all over Europe.

Hops are also grown in France, but their cultivation is not distinguished by any peculiarity or excellence, nor are they grown in nearly such abundance, nor of so good quality, as in England; the demand for them being much more limited, in consequence of the comparatively confined use of beer as a beverage.

Teasels are cultivated with much assiduity in Languedoc, Normandy, and Picardy, for the same purpose for which they are grown in England. Those of Picardy are esteemed the best that grow in France. According to the trades in which they are principally used, they distinguish them into charbonnier, charbon drapier, charbon foute, in general charbon fèu, and the smaller ones are called têtes des liniots, linen's heads. They commonly transplant their teasels in France, in order to improve their heads; and in some places horse-hoe them. Before the Revolution, teasels were regarded as so essentially necessary in the manufacture of woollen goods, that the exportation of them was prohibited, except by licence. But now in France, as in England, their use is in a great measure superseded by improvements in machinery.

Sparta, or sparto grass, a species of fibrous grass, or Sparta junk, grows abundantly on the sea-shore in Provence, and, Languedoc, and some other provinces of France. It is employed not only in the manufacture of ropes, but in that of mats, and a sort of carpet, which is looked upon in France as being extremely ornamental to a room. Swallow-wort, a hardy plant that grows in the south of France, contains in its seed-capsules a kind of silk, that is used for stuffing pillows, and also for manufacturing paper of a superior quality.

The harvest in the south of France generally commences about the middle or end of June, in the central provinces about the middle of July, and in the north of France about the beginning of August; but in the high grounds, especially in Auvergne, the harvest is very late, oats being not unfrequently green in the middle of August. It has already been mentioned, that women are principally employed in the harvest operations: indeed, agricultural operations of all kinds are conducted, more frequently, in France, in a more independent, and less subservient capacity, than in most other countries. The Hainault sike is used in French Flanders, and in parts of the north and east of France: The sike more generally, and the common seythe in some districts, even for the wheat. The harvest operations are by no means carried on with neatness or method; and the excellence of the climate is such, in most parts of the kingdom, that these deficiencies are seldom attended with much loss.

Scarcely any corn stacks are to be seen in France; Thrashing, by far the greatest part of the corn being either put into barns, the size of which, in some districts, is enormous, or thrashed out immediately after harvest, in the open fields; this mode of thrashing, however, can...
be practised only in the southern parts of the kingdom.

the
with a hollow periphery, raises a portion of the water of this canal to the height of 30 feet; an aqueduct conducts it on arches built on the bridge, across the river, to water the higher grounds; while the canal below carries the larger part of the water to the lower fields. Meadows are watered in some parts of Gascony, and in the vicinity of Avignon,—an unusual thing in the South of France.

But the most extraordinary instances of irrigation, are to be met with in the singular desert of La Crau, already described, and in the Pyrenees. In advancing from Salon into the Crau, about four miles before it commences, the road crosses the canal of Borsigelin. "The old canal of Crappone, at the same place, is seen distributing water in various directions, for the amelioration of one of the most arid tracts that is to be met with in the world. The canal of Crappone takes its waters from the Durance at La Roche, and carries it to the southern part of it at Istres. This canal is 40 miles long. That of Bois Selin receives it from the same river at Malavart, crossing the other, divides it into three branches: one of which leads to the lands in the neighbourhood of Istres; the second to St Sauveur and Magran, and this part of the Crau; the third is a small one that turns to the left towards Salon. In consequence of water being thus conducted to a region where it is so much wanted, some very capital improvements have been wrought. Some large tracts of the Crau have been broken up, and planted with vines, olives, mulberries, and converted into corn and meadow." The corn has not succeeded; but the meadows, according to Mr Young, are amongst the most extraordinary spectacles that the world can afford, in respect to the amazing contrast between the soil in its natural and in its watered state, covered richly and luxuriantly with clover, chicory, ribgrass, and avena elatiun.

In describing the irrigation of the eastern Pyrenees, we shall use the words of Mr Birkbeck, who, in his tour through France in 1814, observed every thing relative to its agriculture with the eye of a most shrewd and intelligent observer, and who has recorded his observations in the most clear and impressive manner.

"The copious and pure streams issuing from the Pyrenees, from their source to their union with the Mediterranean, are most economically and skillfully directed to the purpose of irrigation. On the mountain sides, the streamlets, as they trickle from the rocks, are collected into channels, above every little portion of arable ground, which they render surprisingly fertile. These rills uniting, form larger streams; and these, with great labour and ingenuity, are kept up by artificial channels, and only suffered to descend as they perform the office of irrigation. The same attention is paid to the larger streams united, which become a considerable river in the lower lands of Roussillon. This is divided and subdivided, united, and is again divided, so that every portion of the surface seems to enjoy its due share. The soil of Roussillon is sandy, and apparently not very rich; but, by the joint influence of water and sun, vegetation is vigorous beyond any thing I had ever before witnessed. Where a mountain side, or a portion of the land, is so situated, as to be inaccessible to the water, it is planted with vines, to which watering is not applicable, as it injures the quality of the wine, without increasing the quantity sufficiently to compensate. On the contrary, olives, irrigation may be applied with prodigious advantage, an instance of which came under my observation. This crop had ger-

erality failed, owing to the extraordinary coldness of the early part of the summer; and one half of a large olive ground was, like the rest of the country, without fruit; the other half, which had been watered several times, was laden to a degree equal to the most plentiful season. How this country, and other valleys of the Pyrenees, were originally laid out so judiciously with channels of irrigation, systematically arranged for the benefit of the whole, is a mystery I have not heard explained. A master's hand seems to have planned and executed all, before the appropriation of the soil, otherwise private interest would have interfered and marred the design. However that may have been, every man now finds a 'canal d'arrosage' passing above his field, and a 'canal de dessèchement,' at the bottom, which latter is the 'canal d'arrosage,' in its turn for the land below.

The manner of applying the water is extremely simple. A dam is made across the upper channel, from which the water flows gently into a furrow made by the plough along the higher side of the field, and in a few hours soaks through the whole soil, until it reaches the lower side, which completes the operation.

The following, which is one of the usual practices of the district, may shew what this amphibious husbandry can effect. In August, they scratch the wheat stubbles with their little Roman plough, which does not turn a furrow, or move a fourth of the surface. They then sow annual trefoil, which they cover very slightly by planking, that is, drawing a plank on which a boy rides, over the land, thus breaking the clods and smoothing the surface. This is equivalent to our rolling, as the scratching is to our ploughing. The weeds and stubble are but little affected by this process of ploughing and planking. However, that matters not, for the water is now introduced; the trefoil starts as it were instantaneously; and in October or November is three deep, and fed off by the sheep. Water is applied from time to time; and in January or February it is fed again; and lastly, in May it is mown for hay, a heavy crop. Immediately as the hay is removed, another scratch is given, millet or haricots are sown, irrigation goes on, the crop is reaped, and the ground receives four ploughings, as a preparation for another crop of wheat, to be sown in October or November. This is the history of one year, under familiar and constant practice."

The richest arable land, when watered, sells for nearly double what land of as good quality not capable of being watered will bring. Besides the districts already mentioned, where irrigation is practised on a large scale, and with great skill and effect, every spot of land in the mountains of the Limosin is watered; and a considerable part of the vale of the Limagne of Auvergne, as well as some of the mountainous districts of that province. At Isoire near Clermont, the gardens are planted in quick succession by means of it. There are also here what they call vergers; that is, watered meadows planted with apples and other fruit trees, which are very productive. Irrigation is applied to the culture of hemp in Auvergne.

Besides the improvement of the mountainous districts in the centre and south of France by means of irrigation, by another process, calcareous mountains, which generally rise in shelves, are rendered productive by cutting away the rock behind the shelf, which supplies materials for a low wall around the edge. The interval is afterwards filled with earth, and the barren mountain is crowned with luxuriant terraces.
It must have sufficiently appeared, from the account already given of the agriculture of France, that the meadows and pastures of that country bear a very small proportion to the arable land, and that comparatively little dependance is placed on their produce, for the breeding or fattening of cattle or sheep. Indeed as the cattle and sheep of great tracts of arable land are entirely supported on clover, lucerne, &c. and as the climate of by far the greatest part of the kingdom is not well suited for meadows or pasturage, the French agriculturists have little reason to regret, or alter this feature in their husbandry. The author of the Credit National calculates the meadows at 15,000,000 arpent; that is, at one-fourth of what he makes the arable land. But Mr Young conceives that they do not amount to one-third of that quantity, and estimates the meadows and rich pasturage together at 4,000,000 English acres; not 1-17th of the arable land. This seems a very small proportion; but it will not be deemed too small, when it is recollected, that in those districts where in England we find extensive meadows, that is, by the sides of the rivers, there are in France very few, and those very inconsiderable. For instance, the plough moves to the water’s edge of the Marne. There are very few meadows on the banks of the Loire. The Seine is bounded either by hills covered with wood, or by gravelly plains under tillage. The land near the Garonne is principally arable; and the Rhone presents rocks and vines on its banks, through the greater part of its course. On the smaller description of rivers, indeed, there are meadows, especially on the banks of the Saone; but it is evident that these taken together can form a very small proportion indeed of the area of France.

The most extensive, and certainly the most fertile, pasturages in France are to be found in Normandy. The moisture of the climate, aided by the generally deep and rich soil of this province, is extremely favourable to pasture; and as the farmers here are certainly equal at least in intelligence, capital, attention, and skill, to those in any other part of France, those advantages are turned to the best account. The grazing lands of the Pays d’Auge are particularly celebrated; and of these, the Valley of Corbon may perhaps class with the finest to be found in any country. In 1789, when Mr Young visited these pasturages, the rent of the highest was about £4:7:6 the acre, measured by the perch of 22 feet; and the price about £37, 10s. the acre. In several of the provinces, there are also salt marshes that are applied as meadows, to the fattening of cattle, particularly in Normandy, about Iaisy and Carentan, in Poitou, Saintonge, Languedoc, &c.

The management of hay in general is very slovenly. It is not unusual to see the produce of a field carried away in sheets and blankets, or even in the arms, and one-fifth of the crop lying scattered in the roads and the fields. It is in general too much exposed to the sun. The women here, as in all the other parts of agricultural labour, perform the principal part of the work, even pitching the hay into the cart. The fork they make use of for this purpose is a very awkward one. In the central and southern provinces, where the climate is very steady, the farmer stacks his hay in small cocks, where it grows, and only carries it away at his leisure. When carried to the hay loft, being merely thrown together without being trodden, it loses the little fragrance, which a burning sun acting on it, while it was making, had left it. The clover hay, however, especially in the northern provinces, is better managed; after standing for some days in large cocks, it is tied with straw bands, in bundles of 14 lb. each. The lucerne also, in these districts, is got with great care, so much, indeed, that the colour is beautiful; the green is often not in the least faded, but so vivid that it almost appears improved in drying.

Normandy, the Limousin, Auvergne, Brittany, Franche Comté, Poitou, and Burgundy, are most celebrated for their breed of horses. Normandy has long been noted for its horses. It is said that William I. won the decisive battle of Hastings, by the superiority of his cavalry which he brought over with him. The Norman horses are in general low and thick, and very steady, sure, and strong. They will make a stage of 30 miles without a bait, and eat the coarsest food. They, as well as the horses in other parts of France, and also the cattle, are accustomed to feed about the lanes, and in the common fields, after the corn is carried off. The best saddle horses are those of Limosin. They are seldom fit for riding till they are six or seven years old; but then they are very useful, and last a long time. This breed has been lately much improved, by crossing it with the Arabian, Turkish, and English. Auvergne produces some good hacks for common use. A great many foals are reared in Brittany, which are sent to the pastures of Normandy. A great many horses are also bred in Franche Comté, especially in the hilly part of the country. One year with another, their studs produce upwards of 5000 colts, most of which are bought, when six months or a year old, by the horse dealers in Champagne, Burgundy, Brie, and Berry. The trade in horses is consequently an object of some importance and value in Franche Comté. In different parts of the kingdom, there have long been Haras, or dépots de chevaux for the supply of the royal studs; and Bonaparte, sensible that cavalry is one of the main sinews of war, paid particular attention to the breed and supply of horses; but, as in many other things that he undertook, his plans were not calculated to produce the object he had in view, in consequence of the impatience, obstinacy, and tyranny of his disposition. On the whole, therefore, the breed of horses, and probably the number, are not equal to what they were previously to the Revolution. In the year 1802, the total number was, of plough horses 1,500,000; horses kept at Paris 35,100; in all other towns 200,000; in the armies 100,000; making in all 1,835,100. With respect to the number assigned for agricultural purposes, it may appear high, when we consider, that oxen are very much used not only in the plough, but in carts; and that where horses are employed in the plough, there are seldom more yoked than two. The number of horses in Paris is singularly small. Between 1802 and 1812, the number of horses, at least of those bred in the government studs, was probably much increased; but during the Russian campaign, in a few months of 1812 and 1813, the loss, according to the exposé of the year 1814, amounted to 250,000 horses, which, it is stated, could not be replaced at a less expense than 105,200,000 francs. The price of farm horses in the northern districts of France, is about £17 sterling.

Mules are much employed in the middle and south of France, especially in the latter, for treading out the corn. Anjou carries on a particular trade for these animals, known by the name of Mirebalais. In the de-
France.

The provinces in which oxen and cows are principally bred or fattened, are, Perche, Champagne, Lorraine, Alsace, Hainault, Flanders, Normandy, Brittany, La Maine, Anjou, Poitou, Berry, Nivernois, Burgundy, Limosin, Auvergne, Bresse, Languedoc, and Dauphiny. The prevalent colour of the cattle in France, from Calais to the Pyrenees, is a pale redish, or rather a cream colour. This is decidedly the colour of the cattle of the Limosin, which are an excellent breed, probably the best in France. From this district, numbers of fine oxen, fattened in winter, are sent to the Paris market, which is also supplied by those fattened in Normandy during summer. The cattle of the Limosin have short legs, straight and flat backs, well arched ribs, deep and heavy carcases, and their weight from 60 to 80 stone, 14 lb. to the stone. The most singular circumstance respecting them is, that they should be in excellent condition in the month of May, the season when they are usually driven from Limoges to the Paris market, as at this time of the year there is in most countries a scarcity of fat cattle, when they have not been fattened on spring grass; and any grass which they could have in a climate not very different from that of the south of England, could have but a small share in bringing them to the condition in which they reach Paris. The method by which they are brought into this condition is very extraordinary: they are put on grass till the beginning of November; then on rare or turnips. When the turnips fail, they give them rye-flour, prepared in a peculiar manner: the flour is mixed with water, so as to make a paste, which is suffered to stand till it ferments. In some instances the fermentation is promoted and accelerated by the addition of leaven. This rye-paste is never given to the oxen till it becomes sour. At first they refuse it; but when they take to it, they prefer this acid food to any other. A large ox will eat in this manner about 22 lb. of the paste a-day: it is given thrice a-day. The oil-cake of walnuts is also given to oxen in the Limosin, with the greatest success. In some parts of this district, boiled potatoes and chicums are given; in other parts, boiled maize rendered tender by pouring boiling water upon it.

In other parts of France, oxen are fed on leaves. This seems to have been an established custom in the time of Henry IV., and is particularly mentioned by Oliver de Serres, who wrote, under the auspicia of that monarch, the Théâtre d'Agriculture. The practice was formerly usual in England also, in Henry Eighth's time, and even so late as the reign of Charles II. as appears from Evelyn. The leaves used in France are principally those of the beech. They are gathered when on the point of falling, or immediately after they have fallen, and are preserved as dry as possible by being covered with straw. The management of this mode of keeping cattle is best understood in Franche Comté and Auvergne.

Where the Rhône divides between Tarascon and Arles, an island or delta is formed, called Camargue. This island is nearly an equilateral triangle of about seven leagues each way. It was formerly covered with wood, but has for a great many years been cleared, and covered with rich pasture. Vast quantities of sheep and cattle are bred and fattened here. About 3000 horses are computed to be bred annually, with oxen and sheep in proportion. The oxen are reserved chiefly for the supply of the marine at Toulon. They differ in colour from those generally met with in the rest of the kingdom, being a small black breed, not unlike Scotch cattle. They make excellent beef. They are very wild, and often very mischievous; so that when the droves of them go to Toulon, they are always preceded by a man on horseback with a javelin in his hand, who keeps at a short distance ahead of them, to warn people of their approach.

The Norman cows, similar to those of Alderney, are cows, the most celebrated for the quality of the milk they yield. This province, especially the neighbourhood of Isigny in Lower Normandy, and Brittany, especially near Lannion, in the department of the North, and the Boulonnais, supply excellent butter, both fresh and salt. Gournay, a town in the department of the Lower, is particularly celebrated for its market of fresh fresh butter, which is chiefly consumed in Paris. In the neighbour
dom of Marseilles, where cows are seldom seen, milk is furnished from sheep and goats: butter is only made from sheep's milk; a kind of curd is also made from this milk, which is called from the milk is made into little pots, and brought about by the country people for sale. Cheese is very little made in France. Languedoc, Provence, Brittany, Normandy, Forez, and Bresse, furnish it in the greatest quantity. That of

FRANCE.

Brie is esteemed the best. On the borders of the Saone are a range of hills which from their excessive fertility are called Monts d'Or. Several villages are dispersed over them, in which a very small delicate cream cheese is made. They are sent to very distant parts in little boxes, made exactly to the size of the cheese.

It is calculated that the number of oxen employed in husbandry are about 3,600,000; feeding oxen 104,500, young oxen, 1,465,000; cows, 1,016,000; making a total of 6,084,500.

The native breeds of sheep in France are, 1. The Sheep, 2. The Norman, with red legs and faces, and coarse wool. 3. The Berry, resembling somewhat the South Down sheep; the wool fine. 4. The Rousillon, similar to the Spanish, with very fine wool. 5. Near Mirepoix, in the department of the Upper Pyrenees, there is a sort of sheep, resembling the Norfolk breed, with horns, black faces, and legs. The leading characteristics of the native French sheep are their long legs, thin carcasses, and coarse wool; the mutton in general is prevailingly coarse, and is not equal in quality to the mutton of the Spanish breeds. Some of the sheep of the Pyrenees are of a peculiar breed, resembling the Spanish breeds in their general characteristics, but in their wool, differing in many respects. The sheep of the Pyrenees are in general not considered superior to those of the plains of France. The sheep are chiefly used as draught cattle, and for the production of mutton and wool.
lished a decree, by which he intended and hoped to cover France with fine-woollen flocks; but, by this ill-advised measure, the final blow was given to the Merino breed. From that time they have been declining in France. In the expose for the year 1814, it is asserted that Bonaparte's forced attempts to introduce the Merino breed of sheep, cost the government 200 millions of francs; and that, after all, so far from succeeding, the breeds of native sheep were rather deteriorated.

Sheep are kept in all parts of France, but principally in Roussillon, Languedoc, Provence, Dauphiny, Auvergne, Guienne, Gascony, Bearn, Marché, Limosin, Poitou, Maine, Anjou, Brittany, Touraine, Champagne, Alsace, Franche Comté, Normandy, and French Flanders. In most parts of France, the sheep are shut up in stables at night, and sheltered from the sun at noon during the summer. They are generally folded in the fields till November. When the snow is deep, they are sometimes fed on the branches of trees. On the whole, the management of sheep is bad in France, especially in keeping them too hot during night in their houses, and too confined in their folds. The flocks are not large, seldom reaching 400.

On the mountains of the Cevennes, which run along the northern parts of the Languedoc, numerous flocks are fed in the summer on the aromatic herbs with which they abound. During the cold of the winter, they descend into the plains. But the most extensive and singular emigration of sheep is that which takes place annually, and as regularly as in Spain, from the Camargue, or Delta of the Rhone, and the desert of La Crau, to the mountains of Provence and Dauphiny, especially to the mountains of Gap and Barcellonetta, and back again. The migration to the mountains takes place in May, whence they return again in October or November, and sometimes earlier. The migration is not regulated by any other written laws, than some acts of the parliament to limit their roads to five toises of breadth. If they do any damage beyond that, it is paid for. The Barcellonetta mountains are the best, as they are covered with fine turf.

The migration is conducted with all the order and regularity of the march of an army. The flocks belong to several proprietors, who reside principally about the Crau, at Arles, Salon, &c. M. Darline, the author of the Natural History of Provence, as well as other writers, calculates the sheep kept in the Crau and the Camargue at one million. They travel in flocks of from 10,000 to 40,000, and are from twenty to thirty days on the journey.

Among the shepherds that have the care of them, one is chosen as chief during the season. He regulates every thing relative to the march, and is treasurer for the company; all the money for the expenses of the route being lodged in his hands, and he paying for every thing. In order to check him, another of the company is appointed secretary. In his presence all payments are made, and he enters them immediately in his book. The rest of the shepherds form a council, whom the chief consults in case of any difficulty. To every thousand animals, three shepherds are allowed, each of whom has his dog. In the centre of the flock, a number of asses March, carrying the provisions and baggage. The chief also takes his station in the centre: he issues the daily allowances of provisions, and transmits his orders, by his assistants, from this situation; and if any irregularty is committed, he is found there to receive the complaint. He also examines into any mischief which may be done by the flocks to the countries through which they pass, and pays the person who has received the injury; he next determines, whether it was occasioned by negligence or through accident: in the former case, the sum paid is levied on the offender; in the latter, it is taken from the common fund.

Besides the sheep, there are always a number of goats, which take the lead of the former. Some of the oldest be-goats have bells round their necks. The discipline in which these are kept, and the intelligence which they display, is remarkable. At the command of the shepherds, they either halt or proceed; and when the flocks rise in the morning, the moment these goats receive the order to proceed, they repair to their stations in the foremost ranks with great regularity. If they come to a stream, they halt, till the word of command is given, when they instantly plunge in and cross it, and are followed by the rest of the flock. When the flocks lie down at night, the shepherds and dogs still continue on the watch, relieving each other at stated intervals. When they arrive at the mountains, each shepherd has his particular district allotted him by the chief. The feed is hired at the rate of 20 sous each sheep for six months; and the price for the winter feed in the Crau and the Camargue is the same. During the whole time of their stay on the mountains, the shepherds live almost entirely on bread and goat's milk, sleeping upon the ground in the open air, or in huts; the shepherds in France never inhabit a house.

Shepherds go to the cottages in which their wives and families live, to take their meals, but sleep in their sheepefold, in huts made of reeds and clay, upon a mat spread on the ground: these huts are placed on wheels. The wages of the shepherds are in general high; and they are a superior class of men, in all respects, to what they are in England. The wages of the chief shepherd are about L.1/2 sterling; besides this, he is allowed a certain sum, often three francs per head, for every sheep sold; his board at one and a half francs a day; and a cottage, rent free, for his family. The wages of the inferior shepherd is about L.8 sterling; and he has the same allowance for board as the chief shepherd.

The Pyrenees breed of shepherd dogs are peculiarly celebrated. They are black and white, of the size of a large wolf, a large head and neck, armed with collars, stuck with iron spikes, so that no wolf can attack them. But bears are more potent adversaries. If a bear can reach a tree, he is safe; he rises on his hind legs, with his back to the tree, and sets the dog at defiance. These dogs are fed entirely on bread and milk. In most parts of France, when it is necessary to catch a sheep, for the purpose of examining it, the shepherd orders his dog to drive the flock round his master, which he does by going round them in a circle, gradually decreasing, till the shepherd takes any one he wants.

The average weight of the fleeces of the native sheep Wool of France is about 2½ or 3 lb.; that of the Merinos about 6 lb. The wool of the former, in general, is of indifferent quality. The wool of Roussillon is the finest; that of Narbonne is nearly as fine, but more cottony, and of a shorter staple. The wool of Beziers is next in quality; that of Pesenas, in Languedoc, on the side of Montagnac, is somewhat less fine. The wool of the sea-coast is heavy and coarse; the wool of the mountains of Montpellier and De Somieres are of three sorts; the first equal to the wool of Pesenas, the second less fine, the third very coarse. The wool of Berry is fine; that of Rheims inferior. The number
of sheep in France is estimated at 30,097,785; the total of the wool they yield may be rated at 106,770,000 lib.

There are a vast number of goats in France, principally, of course, in the mountainous districts. Pigs are chiefly fed in the neighbourhood of woods, or where grain abounds, as Normandy, Champagne, Limosin, &c. They are also fed on acorns; and, in the Limosin, on chestnuts.

Immense quantities of poultry are kept in all parts of France; to such an extent, indeed, that it is a question whether there is more weight of mutton consumed, or of poultry. They are of an excellent quality. Great pains are taken in rearing and fattening them. In French Flanders, as well as in other districts, they are fed with the flour of buck wheat, or rye, or potatoes: their food is frequently changed; and the vessel into which their meat is put is washed with hot water after every repast. After feeding, they are kept in darkness till the next meal. In some parts, what are called virgulaires are expressly kept for them; that is, places in which worms for their food are collected and preserved. Capons are fattened in many parts of the kingdom: those which are fattened at Barbezieux, a town in the department of the Charente, are so much esteemed, that they are sent to Paris for those who keep the most delicate tables.

Narbonne honey is much celebrated, but it is not the produce of the neighbourhood of that place; at least it is seldom to be procured there: what is so called is more commonly, as well as much more abundantly, procured at Perpignan. The bees wax of Champagne, Normandy, Sologne, Languedoc, Auvergne, and Brittany, is esteemed the best. Bleaching wax is a business of importance in France. The yellow wax of Brittany bleaches with the most ease, and becomes a beautiful white: it is principally bleached at Chateau Goutier, about eight leagues from Angers. By some, this is esteemed the very best in the kingdom; by others, that of Champagne is preferred. The wax of Amboise, and of Chaumont near Troyes, is of an inferior quality; and that made at Rouen is esteemed the worst, on account of the large quantity of suek they add to it. At Montpellier, there is a large manufacture of bees wax, and the process is conducted with great attention and skill.

The forests of France are numerous and extensive; and as they have always been of great importance, both on account of the fuel they supply, and of their application to other purposes, many calculations and conjectures have been made with respect to the surface which they cover. The Marquis de Mirabeau represents them as 30,000,000 arpents; in this opinion M. Malpart coincides. By the author of the Credit National, they are reckoned to be only 6,900,000 arpents. Mr. Young endeavours to determine this fact by two methods; by the maps of Cassini and by the consumption of the people. By the first method, he makes the extent of wood about 19,000,000 arpents, or one-seventh of the kingdom; by the other method, he finds, that the quantity of wood is about 20,800,000 arpents; the mean of the two results which he thus obtains is 19,850,515. We have already observed, however, that his estimate is too high, at least it is above that of the committee of the first National Assembly, which reckons the wood only at 13,100,691 arpents. Mr. Young, in his calculation, reckons the annual value of the woods to be about 12 millions sterling, the rent being taken at 12s. per acre.

Some of the forests are very extensive, particularly those of Orleans, the Ardennes, and Fontainebleau. The forest of Orleans lies to the north of that city, and of the river Loire; it contains several plains and villages in it; its whole length is upwards of 15 leagues; but it is of unequal breadth, in some places seven or eight leagues, in others only two or three. It contains great variety of timber, such as oak, elm, aspens, fir, &c. Before the Revolution, the value of the timber annually fell in this forest, amounted to 100,000 livres: the profit was part of the appanage of the Duke of Orleans. It was formerly infested by numerous troops of banditti; and it is still the haunt of immense numbers of wolves. The forest of Ardennes, in the time of Caesar, was the largest in Gaul; it began on the banks of the Rhine, and extended to the very borders of the Iphone, that is to say, the diocese of Rheims in Champagne. In another place he says, it extended from the banks of the Iphine, and the country of Treves, to that of the Nervii, that is Hainaut, Cambresis, and French Flanders, comprehending 50,000 paces in length. This forest has been cut down in a great many places, especially towards its extremities; however, it still extends over the greater part of the Duchy of Luxemburg, in the southern part of the bishopric of Liege, and of the province of Hainaut, and of the northern part of Champagne, though with several interruptions. It was formerly renowned for events of chivalry. The forest of Fontainebleau, anciently called the forest of Biere, contains 26,424 acres of ground, reckoning many empty places, where the trees have been cut down.

The wood of France may be divided into six classes: 1. For ship-building. 2. For the use of house carpenters. 3. For the construction of carriages. 4. For joinery. 5. For vine props. 6. For fuel. Oak is chiefly used for the first class; for the second, oak, fir, linden, and aspen trees; for the third, ash, oak, maple, and especially elm; for the fourth, fir, beech, elm, pear tree, apple, cherry tree, cornel tree, aspen, poplar, linden, &c.; for the fifth, osiers, and branches of different trees; that destined for fuel is divided into new and old, and is distinguished by the names, bois perdus, bois carnard, and bois entrain. The cork-tree flourishes on the French side of the Pyrenees, and produces very fine cork-wood.

Under the old government, the national forests embraced 9,000,000 arpents, and gave about 12,000,000 francs to the royal treasury. By the Revolution, all the forests formerly held by the corporate bodies and the emigrants were annexed to those of the state, which thus were increased to upwards of 4,000,000 arpents. These, added to the forests in Belgium, and on the left bank of the Rhine, in the year 1800, yielded rather more than 70,000,000 francs, according to the budget for that year. All forests above 300 acres were also added to the national domains, and declared inalienable. In the year 1800 the national forests were thenceforward exempted from the land tax. The Revolution did not abolish the arbitrary laws under which the private proprietors of woodlands laboured. According to these laws, the government appointed persons, who were proper judges of ship timber, to examine all the woods, and to mark such trees as they deemed fit for their purpose, after which the proprietor durst not lay the axe to the roots of them. Besides, no individual proprietor of woodland could cut down his timber, or clear his land, under a heavy penalty, without making, six months previously, a declaration of his intention to one of the conservators, whose report determines the government either to grant or refuse permission to that effect.
To this general account of the woods in France, we shall add some short notices of such trees as are sources of national wealth, independently of the timber which they afford, as an appropriate introduction to our account of the vine-husbardry, and the wines of France.

The fine turpentine-tree is found in the southern parts of France, as well as in the isle of Chio, and in the Indies: the juice is the Chio, or Cyprus turpentine of the shops. Considerable quantities of turpentine are also made in the vicinity of Strasburg, from the silver fir; it is known by the name of Strasburg turpentine.

Beech oil. Beech oil, drawn by expression from the mast of the beech tree, after it has been shelled and pounded, is very common in some parts of France, especially in the department of the Aisne, and is used instead of butter. After the oil has been extracted from the mast, the marc, as it is called, is also used for food, in various ways; sometimes simply as the extraction leaves it, in which state it is also given to poultry, pigs, oxen and cows; or as flour, being ground in a flour-mill and bottled; or as a kind of cheese, (fromage,) in which case, as it comes from the press, it is moistened with milk, and kept in crocks. The Barging, as Franche Comté, the marc of walnuts is made into this kind of fromage, after the oil is extracted from it. Walnuts are grown very extensively in France, and a great deal of oil is made from them.

Chesnuts. Chesnuts abound in France, particularly in the Limoisin, where the land is almost every where covered with chesnut trees. The fruit serves for food to the country people, but not, as has been asserted, reduced into flour to make bread. Their manner of preparing chesnuts for food is as follows: they take off the first peel or rhind, when they are dry, then they boil them a little, to take off the second peel; and afterwards they boil them entirely, to reduce them into a kind of pap. Thus prepared, they are said to afford a pleasant and nourishing article of food to the peasantry of the Limois in, and other parts of France.

Caper shrub. The caper shrub grows in great perfection in the southern provinces, especially in the vicinity of Cuges, between Aubagne and Toulon, where an extensive valley is wholly devoted to the culture of them. The caper is not suffered to grow here, as it does in many places, into a bush; but is made to creep on the ground in long runners, and being cultivated only for the trade, is never left to flower, it being the little bud of the flower that is used for pickling. The fruit also, which resembles a very small gherkin, is pickled; but these have the name of cornichons, the French name for gherkines: it is the flower-bud which has the appellation of capers. When suffered to flower, it is a very beautiful shrub.

Orange trees. The islands of Hieres, not far from Toulon, were formerly famous for their orange groves. In the year 1565, Charles IX. visited these islands in a progress he made through the south of France: he was accompanied by the young King of Navarre, afterwards Henry IV., and the Duke of Aljouj; and there was then an orange tree so large, that these three royal personages, taking each other by the hand, could but just encircle the stem: it had produced in one year 14,000 oranges. But the climate even of the south of France, is not steadily warm enough for this fruit; the severe winter of 1789 killed every tree in the Hieres, down to the roots; and the trees at present there are only such as have shot up from their roots. Most of the oranges of Hieres are sent to Paris. In these islands, and in some other parts of the south of France, the lemon, citron, date, and pomegranate, are not uncommon; the lime is also cultivated, especially in Provence.

The trade of almonds carried on in France is considerable, both on account of their oil, and the large quantity of them used in Lent, either shelled or unshelled: a great quantity of the sweet almonds are used in sugar-plums, and of the bitter ones in biscuits, confectionary, &c. The grocers and druggists of France have both sorts from the provinces in the middle and south of France, especially Provence, Languedoc, Touraine, the county of Venaissin, Avignon, &c. The best are those of the county of the Venaissin; those from Chiron in Touraine are the worst. The environs of Aix are particularly noted of all parts of Provence, for the abundance of almonds they produce: they are an uncertain produce; a frosty night will sometimes come on, while they are in blossom, which is commonly about the end of January, and in a few hours the greatest part of the crop will be destroyed. At the time when the almonds are gathered, it is a curious sight at Aix to see the women sitting at their doors cracking them for the merchants. The shells being an excellent article of fuel, great interest is made to get the almonds to crack, which is paid by having the shells: a certain measure in the shells is expected to produce a certain measure without them. The person cracking them has a basket of fruit on one side of her, and another basket on the other side to receive them when cracked: she has a flat piece of stone on her knee, and a bone with a knob to it in her hand; and laying the almond on the stone, she strikes it with the bone, which seldom fails to crack it at the first stroke: it is then thrown shell and all into the receiving basket, and when that is full, the almonds are emptied out upon a large table, and the kernels picked from among the shells. The whole process is performed with wonderful dexterity and rapidity.

Figs are another important article among the productions of Provence, as well as of several other districts of the south of France. The most celebrated is a very small green, or white fig, as it is often called, which grows only in the territory of Marseilles, whence it takes the name of the fig of Marseilles. Brignolles in Provence, a town about thirty miles from Marseilles, is one of the most famous places in the kingdom for the dried plums, which are so well known by the name of French plums. Prunes, or St Catherine's plums, constitute a lucrative branch of traffic, almost exclusively carried on at Tours and Chatellerault. These plums are gathered at La Haie, Sainte Maurevaux, Maudion, &c. They are prepared with the greatest care at the places where they are grown; and sent to the merchants of Tours and Chatellerault, who supply every other part of France, as well as foreign countries, with them. The grand purchases of this fruit are made at the commencement of the new year, and of Lent: during the latter season, the demand is particularly great at Paris, and in other large cities and towns in France. Dried plums of excellent quality are also prepared at Agen, Cutoon, Tonlouse, and Bourdeaux.

Mulberries succeed best in the olive climate of France; Mulberries. Tours being the only place north of the maize climate, where they are cultivated for silk with any success; the spring frosts being fatal impediments to their culture in the central, and even sometimes in the southern districts of the kingdom. Considerable experiments have been made for introducing them into Normandy, &c. but without success. In proceeding from Paris to the south, they are not met with till we come to Caude near Montauban; there are a few at Aube; and
even at Tours, the district in which they are grown is of small extent. Before the time of Henry IV. the mulberry trees had been propagated for silk worms only in the Lyonnais, Dauphiny, Provence, and Languedoc; but that king carried them as far north as Orleans; he also planted them near Paris, and attempted to breed silk worms at the Thuilleries, Fontainebleau, and the castle of Madrid, but without success. In the Lyonnais, the white mulberry succeeds extremely well: it is a great many silk worms are reared: the worms are kept in houses, and the leaves carried to them. It is a singular spectacle to see whole trees stripped of their leaves, and bearing the appearance of winter when other trees are in full foliage. A second crop of leaves, however, comes out, but not with the beauty and luxuriance of the first; and they are often gathered to give to the sheep and cattle when other food fails. The white mulberry tree bears a more delicate kind of leaf than the black, for which reason they are always given to the silk worms, as the silk produced from them is of a much finer quality: the fruit is vapid and good for nothing. The leaves are purchased and paid for according to the size of the tree, by those who keep silk worms, but have not mulberry plantations of their own.

The limits of the olive climate have been already defined: They comprehend a very small portion of the south and south-east of the kingdom. In France, there is a great difference in the quality of the oil produced from them; that of the territory of Aix is reckoned the finest. Here the trees are very small, commonly from about eight to fourteen or fifteen feet in height. About Toulon and Hiers the trees are taller, but the oil is of a less delicate quality. The tree resembles a pollard willow in its general appearance, and is by no means either beautiful or picturesque. The fruit is gathered green for making the oil, but if left to ripen, it becomes almost black. When they are preserved, or pickled, they are salted first for a few days, and then put into jars with oil and vinegar. In most houses in Provence lamps are used in the kitchen instead of candles; and among the lower classes they are used universally. Olive oil is used in them. The wood of the olive tree makes excellent fuel when a brisk fire is wanted; but it partakes so much of the greasy nature of the fruit, that while it burns very bright, it also consumes very fast. The time of gathering the olives is soon after the vintage. In the hard winter of 1789, so many olive trees were destroyed by the frost, and during the Revolution so few young trees have been planted, that Aix, which was the principal seat of the commerce in oil, has almost entirely lost this its first and most lucrative branch of trade; and as these trees are many years in coming to perfection, this loss is not likely to be soon compensated.

As there were ales and customs levied on the consumption and export of wine previously to the Revolution, it might have been supposed that the quantity of vineyards in the kingdom might have been estimated with a tolerable degree of certainty, yet there is an amazing difference of opinion on this subject. M. de Trone, author of a work on the provincial administration of the taxes, is of opinion, that their extent is 1,600,000 acres. In this calculation M. Mirabeau coincides; but the author of Credil National, who published only one year afterwards, calculates the quantity at 18,000,000 arpents. M. Lavoisier supposes the produce 80,000,000 livres. The economists in the Encyclopedia, make the annual produce 500,000,000.

Statistics.

This, at an average produce per acre of 175 livres, would give 2,857,142 acres. Mr. Young, after considering these and other calculations, gives it as his opinion, that the vine is cultivated on an extent that constitutes nearly the twenty-sixth part of the territory of France, or about 5,000,000 acres; and that grapes form about one-sixth part of its produce.

The vine is cultivated on all kinds of soil: On the noble and fertile plain of the Garonne; on the richest lands in the vale which extends from Narbonne to Nimes; in the vales of Dauphiny and the Loire; and, in short, on every sort of land in the wine provinces. They are, however, perhaps most generally planted on rocky and inferior soils.

The general routine of cultivation is as follows: Cultivation The vines are planted promiscuously, three or four of the feet, or two and a half from each other. In the middle vine of January they give the cutting, tailles; in March they dig the ground; in April and May they plant the prunins; in June they hoe the seps, they are tied to the props with small straw bands,—the hoe which is used is crooked; in August they again; in October, or if the season has been favourable in September, the vintage takes place. To plant an arpent of vines costs in all 50 Louis d'or. There are 5000 plants on an acre, 2400 seps. The props cost 500 livres; to keep up the stock of props 30 livres annually. It is three years before the vines bear any thing, and six before the wine is good. The amount of labour per acre is about £2:12:6. The net profit varies from 7 to 10 per cent. Great attention is paid in the choice of the bunches, and in freeing every bunch from each grape that is the least unsound. Sixty women are necessary to gather the grapes for four pieces of wine. Such is the general outline of the culture, &c. of the vine in France. The variations from this mode will be afterwards noticed.

I. The province of Champagne, which is now divided into the departments of the Marne and the Higher Marne, has long been celebrated for its vineyards. In this district there are two kinds of wine; the white wines, called Riviere de Marne wines; and the red wines, called Montagne de Rheims wines. The white wines are produced from vineyards situated in the valleys, and upon the sides of the hills in Epernay, Dizy, Avenay, Craymant, &c. It is a singular circumstance, that the estate of Cumières, in the midst of so many vineyards celebrated for white wines, and under the same exposure, produces red wines only. The country producing the fine white wine, is all contained in five leagues length. Among all the vineyards on the Marne, the cantons of Hautvillers, Mareuil, Cumières, and Epernay, are the most advantageously situated: They extend along the Marne; and it is remarked, that the quality of the wine falls off in proportion as the vineyard is distant from the river. South exposures on the banks of this river produce excellent white wines. The slope which overhangs Rheims is divided according to the quality of its wines: Of these, the wines of St. Thierry are the most celebrated; but the wine properly called Clos St. Thierry, which is produced in the archbishopric of Rheims, is the only wine which unites the rich colour and flavour of Burgundy with the sparkling lightness of Champagne. Clos St. Thierry holds the same rank among Champagne wines, that Clos Nogent does among those of Burgundy. Sillery wines, once so famous, were in a great measure composed of the wines produced in the
The price of an acre (100 rods and 22 feet to the acre) of the best vineyard ground in Champagne, varies from 2000 to 6000 livres; the vineyards at Ay selling as high as 6000 livres. The price of an acre of the second quality varies from 1000 to 3000 livres. The ordinary expense of cutting, hoeing, treading, and pruning the vines, is 80 livres the acre; of occasionally propping such as have fallen, 60 livres; of props, 16 or 15 bundles, 50 in each bundle, 30 livres; dung and carriage of the vines, 42; five puncheons for the produce of an acre, 50 livres; expense of gathering, pruning, &c. 46 livres; making a total expense per acre of 508 livres. With respect to the produce of an acre of vineyard in Champagne, it is generally understood, that taking the average of 10 vintages, five pieces or puncheons of wine are obtained from every acre; three of these are of the first quality, or choice wines, and two of them are ordinary wines. Valuing the three puncheons of the best wine at 150 livres each, and the two others at 50, the total produce will be 550 livres; from which must be deducted, besides 308 livres for labour, &c. the expense of bottling, cooperage, and fining, 30 livres for the best wines, and six for the inferior; the annual interest of the money laid out in the ground, 100 livres; taxes, &c. 72; making in all, with the labour, 516 livres; which being deducted from 550, leaves 34 livres as the net produce of an acre of vineyard in Champagne, on an average of years. This net produce, however, is very difficult to fix, as the wines of Ay, Haut Villers, Epernay, and Pierry, frequently sell for 300 or 400 livres a piece, while some of the other wines do not bring more than 90 or 100 livres.

It has already been mentioned, that the province is divided into red wines, and some parts of the province by which they are made have been divided. To make red wine, the black grapes in general are only picked and gathered. The juice is allowed to ferment, and the degree of fermentation is ascertained to be advantageous, when a lighted candle cannot be held over the tub without going out. When the fermentation has entirely ceased, the puncheon is hermetically sealed. About the end of December, and if possible in dry weather, the wine is drawn off. About the middle of May, it is again drawn off. A puncheon of red wine contains 240 bottles. In general, the red wines of Haute Montagne are bottled in the month of November, i.e. 13 months after the vintage. The wines of St Thierry can remain three or four years on their lees. The best red wines of Haute Montagne, will keep in bottles in good cellars for six, eight, ten, or twelve years. These cellars (already alluded to) are from 25 to 40 feet in depth. Their temperature is generally five degrees of Reaumur below that of the atmosphere; the variations are seldom above half a degree.

The cost of an acre of vineyard, for red wine of the best quality, varies from 900 livres to 2000. That in Haute Montagne bears the highest price; the second class sells from 300 to 900 livres. The annual expense of cultivating an acre of red wine vineyard, including the expense of vintage and of pruning, is about 200 livres.

Such are the general details of the culture of the vine in Champagne. There are many vineyards, however, and particularly in St Thierry, where the greater part of the vineyards are always raised to the height of about five feet, and supported by props of oak six feet high, and an inch in diameter.

The following are the classes of the white and red wines of Champagne:
FRANCE.

The first class comprises those wines which have long been considered as luxuries at the French, English, and Dutch tables; the second class comprehends wines, which are not much inferior in flavour and quality to those of the first class; in the third class, are comprised the wines most commonly used in France.

As many of the details respecting the managements, &c. of the vineyards and wines of Champagne, are applicable to the other wine districts of France, we shall be more concise in our observations respecting them.

II. The vines in the Bordelais, and generally in the higher Gironde and Gascony, are not suffered to lie on the ground like those of Provence and Languedoc, but are supported by poles, something like hogs in England. The wines produced in this district, are distinguished into Medoc, Haut Brion, Valence, St. Emilion, De Grave, &c. The best Medoc wines, are Lafitte, Latour, and Margaux. Those of *Vins de Grave*, are Haut Brion, Haut Valence, Morigac, Pessac, Laugon, Ville-nave, &c. The *Vin de Lougou*, so called from a small town near which it is made, is reckoned the best of all the white wines of the Bordelais, which are included under the general name of *Vins de Grave*, from the sandy and gravelly soil in which the vines grow. It has very much of the claret flavour. There are other sorts in different districts, such as St. Julien, St. Manubert, Pouillac, St. Laurent, Ludon, Macon, &c. Those which hold the first rank among the white wines, are Carbonnies, Sères, Barsac, Prigniac, Soulnerie, Baume, &c. Of the white wine exported from this district, the total annual amount may be from 85,000 to 90,000 tons. From 20,000 to 25,000 tons used to go to the French colonial settlements in the East and West Indies. About an equal quantity was exported to Normandy and Flanders. Those that are called crude wines of Medoc, are almost all exported to England. The red wines of Haut Brion, Valence, and in general those named De Grave, are sent to Holland, Hamburg, and the Hanse Towns. The best red wines of Montferrant go to Holland. Those of inferior quality, used to go to the French colonies, or the western departments of the kingdom. The white wines of Grave, Carbonnies, Martillac, Loeggnau, &c. are sent to Denmark, Sweden, and the Baltic; but the best of these go in bottles to Paris. The red wines of St. Macaire, formerly went in part for the use of the French navy, partly to Brittany and Normandy, the rest to Bremen and Lubeck.

III. Throughout Provence and Languedoc, the souche, or stem of the vine, is never suffered to grow higher than about two feet from the ground. The shoots of the year are always cut down to the stem soon after the gueudoc vintage. The new shoots put forth every year, are of an amazing length. The grapes grow in a large cluster round the roots of them, and are shaded by the shoots as by an umbrella. The cuttings of the vine are made into faggots for fuel. The vintage begins about the middle of September. The ordinary wines of Provence are not held in much estimation; but there are some of a superior quality, the Muscat wines in particular, which are little inferior to Frontignac. Roquevarre, not far from Nans, is famous for Muscat grapes. Great quantities are dried for raisins. A wine is made in many parts of Provence, called *Vin cult*. It is not the produce of any particular kind of fruit, but made from any common white grape, the juice being boiled after it is pressed, till it is reduced about a fourth, which gives it a richness and sweetness, not to be obtained by any other process. The Muscat wines are boiled in like manner, as are also all the sweet wines. The process of wine-making is very negligently performed in Provence in general; there is no selection of grapes; red, white, ripe and unripe, are pressed promiscuously together. The method of pressing is very rude and simple. A man, and commonly two or three children, pull off their shoes and stockings, and jump into the vats, where they trample on the grapes till all the wine is pressed out. The only sort of grape used for drying, besides the Muscat, is a large white grape called the Panse. Four or five bunches of the fruit are tied together, and then dipped into a cauldron of ley of wood ashes and water; as it is boiling over the fire, till the grapes look streaky. Without this process, they would turn black and wither, when laid out to dry, instead of retaining their sweetness and moisture. After the dipping, they are hung upon a line for 24 hours, and then separated, and spread upon a sort of hurdle made of reeds, which is laid out in the sun all day, but taken in at night, to protect the fruit from the dew. An excellent sweetmeat is made in Provence, and in other parts of France, by boiling down the juice and pulp of the grape, freed from the skins and stones, till it becomes a rich syrup, when slices of melon, lemon, pears, &c. are preserved in it. It goes by the name of *confiture raisinée*.

IV. The province of Burgundy, in the opinion of many, produces the choicest of the French wines. The dry, best is made at Baon, Nuizis, Romanée, Premeau, Chambertin, Belz, Coulange, Chassagne, Volnay, Macon, and Clos-Vougeot.

V. Wine is also the produce of many other parts of France. A great deal of the wines made in the Beaujoilais, are sold under the name of Macon. The wines of Anjou and Orleannois are thick and heady. Auvergne, commonly called Cassé Taille, is made at Orleans, and is a full good wine. Another Orleans white wine is Génetin. Poitou produces a tolerably good white wine, which resembles Ithenish. Hermitage is the produce of a vine, which is grown upon the banks of the Rhone, between Valence and St. Vallerie. Near this also, the Cote roti is made. It takes its name from the hill on which the vines grow, being fully exposed to the warm rays of the south sun, which contributes so much to the excellence of the wine. The average yearly produce is nearly 1000 hogsheads. The true *Vin de Cahors*, which has a great reputation, is the...
produce a range of vineyards, very rocky, on a ridge of hills to the south of Cahors, and is called Vin de Grave, because growing on a gravelly soil. The wine of Condrieux, a small town in the Lyonnais, on the banks of the Rhone, about seven leagues from Lyons, is very much esteemed. The original plants from which this wine is made, were, according to tradition, brought from Dalmatia, by order of the Emperor Probus.

Luscious wines are common in other parts of France, as well as Provence, of which those of Crotat and St. Laurent are the most esteemed. Frontignac, a town in the department of the Herault, is remarkable for its excellent muscadine wines. They are the most perfect, and the best adapted for keeping. Lunel, an old town in the department of the Gard, is another place, in the vicinity of which muscat grapes are cultivated in great quantities, the soil being particularly suited to them. The muscadine of Lunel is of a more delicate flavour than Frontignac, but it will not keep so well. The muscat grapes grown here are also dried, and are sent all over Europe. They are called in the country passerilles. Aubagne, between Marseilles and Toulon, produces also muscadine wine. The Malvoisie d'Aubagne, as it is called, is particularly celebrated. The muscadine of Rivesaltes, a town in the department of the Eastern Pyrenees, is richer than either Frontignac or Lunel, and comes very near the Cape wine. Beziers is of a quality inferior to Rivesaltes, Frontignac, and Lunel. Liqueurs of various sorts are made in different parts of France. Those of Montpellier are most esteemed. In the beginning of the last century, France exported, upon an average of five years, from the year 1720 to 1725, annually wine to the amount of 20,850,000 litres; in 1778, the exportation amounted to 24,570,170; in 1788, to 39,082,100. The Revolution nearly annihilated the exportation of French wines.

Brandies. The brandies made in France, are esteemed the best in Europe. They are distilled in every part of the kingdom where wines are grown; and in the distillation, not only wines of an inferior, but also those of the best quality, are used. The brandies most celebrated, or made in the greatest quantities, are those of Bordeaux, Rochelle, Cognac, Charente, Isle of Rye, Orleans, the country of Bessois, Poitou, Touraine, Anjou, Nantes, Burgundy, Champagne, &c. Brandy is also a great article of trade at Montpellier. It is of a milder quality than most of the brandies of the south of France, and therefore better adapted for making the liqueurs, for which Montpellier is so celebrated. Of all the French brandies, those of Nantes, Cognac, and Poitou, which are nearly of the same quality, are the most esteemed, because they have a finer taste, and are stronger. The English, Dutch, Flemish, and Huggers, used to take off the greatest part of these brandies. The brandies of Anjou, Touraine, Orleans, which are not of so good a quality as those of Nantes, &c. are most commonly sent to Paris, and into Flanders. In the beginning of the last century, the value of the brandy exported, amounted annually to 5,823,900 livres; in 1778, to 4,689,621; in 1784, to 11,350,200; in 1787, to 14,689,600; and in 1788, to 14,657,300.

Vinegar. Vinegar is made in Provence, Guienne, the Orleans, Anjou, Amiens, Brittany, &c. The Orleans vinegar is esteemed the best. The flavour of the vinegar made in Provence is also good, but being of a red colour, from the hue of the grapes from which it is produced, it has a singular appearance to a person unused to it. The exportation of vinegar in the beginning of the last century, amounted annually to 8,400,000 livres; in 1778, to 141,893; in 1784, to 124,400; in 1787, to 130,900; and in 1788, to 201,700. Cider is made in most of those provinces, the climate of which is not favourable to the grape. Normandy is particularly celebrated for this liquor, where they also make brandy of it.

We shall conclude this Chapter with a few words respecting French horticulture. The fruit gardens at Montreuill are a curious instance of the accumulation of capital in a small space: These gardens are said to be worth 5,000 sterling an acre. All the occupants are proprietors. The environs of Lyons are celebrated for their excellent artichokes: They are carefully conveyed in great quantities to the tables of the rich all over the kingdom. Vegetables for the table are also cultivated in great perfection in Provence, and particularly about Aix. The country for some distance without the town, especially on the south side, is a continuoel scene of kitchen garden. The vegetable for which they are most famous, is what they called cardes; a plant, very much resembling the artichoke, but not growing to a head in the same way. The roots always make part of a Christmas dinner. Aix is so famous for them, that at this season presents are sent of them from thence all over the country. The salads of Aix also, particularly in winter, are esteemed uncommonly good. The tomato or love apple, the aubergine or fruit of the purple egg plant, gourds, and capsicums, are likewise much cultivated in the gardens of Provence. The inhabitants of Roscoff, a town on the northernmost point of the department of Finisterre, particularly apply themselves to the raising vegetables for the table; and in this they are so eminently successful, that Brest, Morlaix, and several other towns, draw their supplies almost entirely from them; and they are sometimes sent as far as L'Orient and Quimper, in the southernmost districts of the department. Cauliflowers, brocoli, cabbages, turnips, asparagus, and artichokes, are especially produced here in amazing abundance, and of an excellent quality.

But though France has made great advances in the useful branch of horticulture, she is far behind in the ornamental: The strait avenue, the terrace, and the parterre, with formal basons, and jets-d'eau, are still the only objects which, in the opinion of the generality of Frenchmen, can constitute real grandeur and beauty in a garden.

CHAP. V.

Manufactures of France—Historical notices of them and their situation and state previously to the Revolution—Effects produced on them by that event.

The consideration of the agriculture of France has detained us long. The account of the manufactures and commerce of that kingdom will not occupy nearly so much space; for France always has been, and probably always will be, more distinguished by the productions of her soil, than by the productions of her manufacturing and commercial industry.

In considering her manufactures and commerce, we shall, in the first place, present some historical notices respecting them, pointing out their origin and their principal eras, so far as they can be ascertained. In the second place, we shall give an account of their state and condition previously to the Revolution; And, lastly, we shall notice, in most cases briefly and gene-
rally, but in some instances more particularly, the effects which that event has produced upon them. We are induced to dwell more fully on their state previously to the Revolution than since it occurred, from two considerations: In the first place, even if their state since could be accurately and impartially ascertained, it would afford no just and permanent picture of them, on account of the great fluctuations, or rather the great depression, to which the Revolution must have subjected them; but, in the second place, it is impossible to gather correct details regarding the manufactures and commerce of France as they now exist: for, although annual exposés have been published, yet the falsehoods and exaggerations which they notoriously contain, peremptorily prohibit us from placing any faith in them. All that we know, in general, is, that by the revolutionary wars the commerce of France has been almost annihilated, and that many branches of her manufactures have been greatly depressed. As, however, her commerce will probably, when it revives, revert into the channels in which it flowed previously to the events which have nearly destroyed it, and as such also will probably be the case with her manufactures, we have deemed it proper to consider more particularly their state previously to the Revolution, sub-joining what information we have been able to collect regarding the effects that event has produced on them. And first, with respect to her manufactures:

1. The earliest notice which we can trace of any branch of the manufactures of France, occurs in the fourth century. It is afforded by St Jerome, in his second book against Jovinian, where he speaks of a manufactury of stuffs which was then at Arras, and which was much esteemed. But the first establishment of a cloth manufactory in France, a branch for which it has always been greatly celebrated, cannot be accurately traced. That they were extensive and important in the beginning of the 14th century, is evident from some letters which exist from the King of France to the King of England, in which he expresses great anxiety to procure English wool at St Omer and Lisle. In 1346, the King of France attempted to detach the Flemings from the interest of King Edward, by sending them the wool of France at a low price, and obliging his subjects to use no other wool, while their cloth made of French wool was to be procured: Thus offering to sacrifice the woollen manufacture of his kingdom. The next notice we have of the manufactures of France occurs in 1453, at which period some branches of them appear to have flourished considerably. This is evident from the account which her historians give of Jacques Coeur, who, by his loan of 200,000 crowns, greatly contributed to enable the King to expel the English. This merchant, at a time when trade was scarcely known in France, is said to have employed 300 factors to manage his vast commerce, that extended to the Turks and Russians in the East, and the Saracens of Africa, at that period the most remote nations known to the merchants of Europe. His exports consisted chiefly of woollen cloths, linens, and those of the principal manufactures of France; and his returns were silks, which proves that this manufacture was not then established, or at most only in its infancy, spiceries, &c. Indeed we know, from other sources, that the first considerable and regular attempts to establish the silk manufacture, occurred in the reign of Francis I. in the year 1521. This monarch took great pains to procure workmen from Milan, while he possessed that duchy. In this manufacture the French made a great progress, principally at Lyons, and other parts of the south of France, and soon supplied many parts of Europe with silk goods; yet it was long after this time, as we shall afterwards shew, before she got into the method of raising raw silk from the worms. In the reign of Henry III. some attention was paid to manufactures. At this period they were neither numerous, nor advanced to a state of any perfection. Articles of elegance and luxury were imported from foreign nations, and even such as were of general consumption had not attained beyond their infancy. Leather and parchment, however, were prepared with some dexterity at Troyes in Champagne; and this place was likewise renowned for the goodness of its dyes, in which occupation the inhabitants were principally employed. A manufacture of white paper was established at Brignolles, in Provence, about the beginning of Henry the Second's reign; and there seems to have been others in the kingdom. In the manufacture of iron and steel the French were then very deficient. Their fire arms they procured from Lombard. Charles IX. indeed, endeavoured to introduce among his soldiers musquets made at Metz and Abbeville, where manufactures of arms were established, but they were so heavy and awkwardly made that the attempt was laid aside. The same monarch brought to Paris, Italian manufacturers, who finished there the morions, or head-pieces, which were manufactured and purchased at Milan. In the reign of Henry III. gunpowder was made in France, but not in sufficient quantity to render the importation of it, as well as of saltpetre, unnecessary. Genoa, in particular, supplied the French with gunpowder.

But the first grand era of the manufactures of France must be fixed in the reign of Henry IV. The monarchs before him had occasionally encouraged particular manufactures; but their encouragement being partial and temporary, and not proceeding from any clear or profound views on the subject, went a little way in the completion of the object they had in view. Henry IV., on the contrary, maturely considered the best means for promoting and cherishing manufactures; and though we can hardly suppose that Sully, who greatly preferred agriculture to manufactures or commerce, entered very cordially into the views of his master, yet there can be no doubt that Henry profited by his penetration and good sense. Before this reign, the silk-worm and mulberry trees had been propagated only in the Lyonnois, Dauphiny, Provence, and Languedoc; and so destitute was France of articles of luxury, that in 1599, Henry issued an edict prohibiting the importation of foreign silks. The inhabitants of the city of Tours had extorted from him this prohibition by their importunities, undertaking to supply all the national demand for silk, as well as for gold and silver stuffs. But they could not perform their engagement; and in 1603, the King was obliged to rescind the edict. Sully entertained great and almost insurmountable prejudices against the silk manufacture, and was impressed with the belief that the climate of France was unfavourable to rearing the silkworm. Henry, however, was not to be discouraged. As we have already mentioned, in 1603, temporary buildings were constructed at Fontainebleau, at the castle of Madrid, and at the Thilleries, for silk-worms. Mulberry trees were planted in various provinces, in which they had not been previously cultivated, especially in the vicinity of Paris, Orleans, and Tours. The government caused pamphlets on the art of cultivating these trees, and preserving the
null
brought Vanrobais from Holland, granted him a patent, and settled him and his workmen at Abbeville. By this patent, which was dated in October 1669, Vanrobais obliged himself to act on foot thirty woolen looms, with as many fulling-mills as should be necessary, and procure fifty Dutch workmen to be employed in the manufacture. Encouragements and privileges, similar to those granted to Cadene, were also bestowed on him. In 1661, having punctually fulfilled his engagements, he obtained a renewal of his patent for fifteen years, on condition of setting up fifty looms instead of thirty. In 1668, a third renewal was granted for ten years, to the brothers and sons of the projector, who had now eighty looms in their manufacture. In 1708, the looms exceeded a hundred; and there were about six hundred men, women, and children, employed upon the spot, in picking the wool, winding, warping, weaving, shearing, &c. At this time, a fourth patent was granted, in which the King gave permission to all noblemen to enter into partnership, without derogation to their titles or honour; and, to encourage the sale of these and other French woollen goods in Turkey, he advanced money to the merchants of Marseilles out of his treasury, to be repaid after the return of their ships from Turkey.

3. We have already mentioned, that Henry IV. established a manufacture of tapestry in the suburbs of the metropolis, but that it does not seem to have succeeded. This manufacture was revived with more success by Colbert: it obtained the name of Gobelins, because the house where the manufacture is carried on was built by two brothers, whose names were Gobelins, who first brought to Paris the secret of the beautiful scarlet dye, which has preserved their name, as has also the little river Bievre, upon whose banks they first settled. Colbert purchased the ground from these brothers, for the purpose of establishing there a manufacture of tapestry, similar to that of Flanders. He was particularly anxious on this point, in order that he might procure suitable furniture for the royal palaces, which he had rebuilt and ornamented, particularly the Louvre and Thilleries. With this view, he collected together some of the most able workmen in the kingdom, in all sorts of manufactures and arts, particularly painters, tapestry-weavers, engravers, goldsmiths, and workers in ebony. The tapestry-weavers were procured from Flanders; separate superintendents of the raised and of the smooth tapestries were appointed; and another Fleming was vested with the management of the wool-dyeing department. The manufacture of tapestries commenced in 1663, but did not flourish till 1666, when it was endowed with many privileges, and denominated, in the edict, the Royal Manufactory of the Crown Furniture. At length, the celebrated painter Le Brun was appointed chief director of the Gobelin manufactures, to which he communicated that beauty and grandeur, which his admirable talents were so well calculated to introduce. The tapestries were brought to a high state of perfection during the administration of Colbert and Louvois. During the administration of the former, Alexander's battles, the four seasons, the four elements, and the history of the principal acts of Louis XIV. from his marriage to his first conquest of Franche Comté, were wrought at the Gobelins, from the designs of Le Brun. Louvois caused tapestries to be made, during his administration, after the most beautiful originals in the king's cabinet of Raphael, Julio Romano, and other famous painters in the schools of Italy, which were first drawn in larger dimensions by the most able French painters, such as La Fosse, the two Coppels, Jouvenet, Person, &c. The Gobelins manufacture, at one period, experienced a decline. Great abuses had crept into it; to remedy which, and revive the establishment, many committees were held at the house of M. Fagon, the financier, in 1737. At this time also considerable improvements were made in the mode of using the paintings, after which the tapestry was to be manufactured. There has always been an academy within the manufacture, in which the youths designed for artists are instructed in the various branches of the art, at the expense of the nation, and are also taught the other trades attached to the Gobelins. The wool and silk used in the tapestries are dyed in a part of the manufacture appropriated to that purpose, as it would be otherwise very difficult to procure the infinite variety of tints and shades, which are required. The materials are ready spun wools from the south of France, and the silks of Lyons.

4. Louis XIV. seems to have been particularly anxious respecting the complete establishment and the perfection of those glass manufactures, which had been introduced by Henry II. and Henry IV.; but his efforts at first were unavailing. Artists were brought from Venice, and the king, for their encouragement, granted the directors and proprietors many privileges and immunities, and supplies of money. He was not, however, disheartened by his failure at first, but by perseverance at length succeeded to such a degree, that the glass manufactured at St. Gobins was superior to that of Venice, both in quality and quantity. In order to facilitate and secure a good market for this manufacture, Louis, by an edict, laid a duty upon foreign glass imported into France to such an amount, as nearly to prohibit it; and a few years afterwards, finding that the home manufacture had still need of further protection and encouragement, he absolutely prohibited the importation of foreign glass. One circumstance in particular seems to have retarded the establishment and progress of this manufacture at first. We have already mentioned, that in the reign of Henry II. and Henry IV. it was established in the immediate vicinity of the metropolis; the consequence was that a scarcity of wood was felt; and it was removed into the neighbourhood of a large forest, with the advantage of a river, to ease the expense of carriage. This forest was that of St. Gobins, whence the manufacture took its name. The whole is situated at the top of a small hill, close to the village of St. Gobin, near La Fere and Chauny, two towns in Picardy. The very white sand used in the manufacture is brought from the neighbourhood of Creil, a place 11 leagues distant from Paris: the glasses are sent by water to the capital, where they are polished and silvered.

Louis XIV. encouraged other manufactures besides those which we have just mentioned. By an edict of the 19th of October 1668, he granted to Noel de Varennes different immunities, to encourage him to carry on the manufacture of Drap de Londres, or cloth made in imitation of what was sent from London to Turkey, in the province of Languedoc. Afterwards that province was obliged to furnish Magi and his partners with 30,000 livres to carry on the same manufacture at Clermont and Sette. It also appears by another edict that this Monarch yearly appropriated a million of livres, exclusive of indulgences in the customs, to engage and reward skilful masters and artificers, who undertook to set up fabrics of cloth, silk, camel and
The great Privilege of settling a tin manufacture in different parts of the kingdom. By an act of 1703, it appears that the manufactures of bays, perpetrators, and serges, which had been set up, after the union between the crowns of France and Spain, had already attained such perfection as to rival those of England.

Towards the close of the 17th century, the manufactures of France were not only very numerous, but many of them were carried on to very great extent, and supplied foreign nations. She supplied almost all Europe with all kinds of curious manufactures, toys, &c. England received from her a vast quantity of silk, linen, sail-cloth, canvas, beaver hats, glass, watches, clocks, paper of all kinds, iron ware, principally the manufacture of Auvergne, shalloons, tammies, &c. from Picardy and Champagne, wines, and brandies; and Holland received most of these articles, besides saffron, soap, wood, honey, &c. The revocation of the edict of Nantes in 1684, gave a fatal blow to some of the most flourishing and lucrative manufactures of France, and may be said to have done them far more mischief than they had received benefit, by all the measures of Louis in their favour. The people whom he thus violently forced out of his kingdom, were generally, throughout all France, the best merchants, artificers, and manufacturers of that kingdom. Those who had most money retired into England and Holland; but the most industrious part of them settled in Brandenburg, where they introduced the manufactures of cloth, serges, stuffs, druggets, crepes, caps, stockings, hats, and also the dyeing of all sorts of colours. The goldsmiths, jewelers, watch-makers, and carvers, settled in Berlin. From this account, and from the additional fact that England is indebted to the refugees for her silk manufactures, and also for improvements in the manufacture of paper, hats, glass, watches, cutlery ware, jack's, locks, surgeon's instruments, hardware, &c. we may form a pretty clear, and accurate opinion, both of the state of manufactures in France, at the period of the revocation of the edict of Nantes, and of the irreparable mischief which Louis inflicted on those manufactures by that revocation.

The most important circumstance in the history of the manufactures of France, during the 18th century, previously to the commencement of the Revolution, respects the establishment of the cotton manufacture. The precise era is not accurately known; but it was certainly carried on at Rouen in Normandy, a considerable time before the middle of the 18th century; and it is said to have been introduced by a Mr Holkar, probably an Englishman. Before the year 1747, the manufacture of cottons, or cotton-linens as they were then called, was established at Nantes in Brittany, where it was supposed it would succeed better than in Rouen, as cotton, wool, and indigo were cheaper. Such are the principal facts in the history of the manufactures of France; we shall now proceed to consider their state, before they were affected by the Revolution.

It may be proper to premise, that they are considered to have flourished most between the years 1650 and 1750; and that, subsequently to the last period, several causes, but chiefly the rivalry of English manufactures, acted unfavourably on them. The following are the principal manufactures which were carried on in France, before the Revolution, most of which still exist, though several of them are now very much depressed.

1. The woollen manufacture. Cloths of different qualities form the most important and extensive part of this manufacture; and the finest cloths are those for which France has always been chiefly celebrated. The very super fine French cloths are made at Louviers in Normandy; those of Abbeville, in Picardy, though fine, are not to be compared with them in quality. The Londrines, made at Carcassonne in Languedoc, which were formerly the most successful manufacture in France, so far as concerned the rivalry of England, and were manufactured expressly for the Turkish and Chinese markets, are also of fine quality. The cloths of Julienne, and the superfine fabrics of Sedan, as well in scarlet as in other bright colours, and in black, are fit only for the rich. Fine cloths are also manufactured at Rouen, Darental, Valenciennes, Montauban, in various places in Languedoc and Champagne; but these are of various degrees of fineness, and applicable to various purposes. Those of Andelis in Normandy are fine mixed cloths, similar to such as are made at Abbeville. There are fabrics of a second sort of cloth at Elbeuf in Normandy, and at Sedan; those of Elbeuf are best suited for workmen and mechanics. Chatanurouge, before the Revolution, furnished a great deal of livery cloth. Romarantin, Issoloren, and Lodève, furnish cloths for military clothing. There are still inferior coarser cloths, made for the wear of the paysans and country labourers. The fabrics at Rheims, before the Revolution, beside the sort called draps de Rêmes, consisted of an imitation of Silesian drapery, called Silesies, imitations of our Wilton's, called willtons, and casimères, which they called maroës. Ratteens were made at Roybons, Crest, and Saillans; cloths and ratteens at Romans; cloths for billiard tables at St Jean-en Royans. Cloths of different descriptions and qualities were also made at Grenoble, Valenciennes, Troyes, St Leo, Bayeux, Amboise, Niort, Coutange, Lisignon, &c. In the rank of coarse cloths, may also be placed the woollen stuffs of Aix, Apt, Tarascon, Oleron, Orthez, Bagneres, Pau, Auch, the valley of Aure; the cloths of Cevennes, Sommieres, Liesou, &c. The greater part of these cloths bear the names of the various places in which they are fabricated. Besides cloths, properly so called, camlets, callimancos, baizes, kerseys, wool and hair plusses, are made at Amiens; druggets, flannel, blankets, at Rheims; blankets in the suburbs of Paris; flannels at Beauvais; serge at Aumale, Bicoum, &c.; camlets and plusses at Margny; hosierly at Conques and Rheims.

In endeavouring to ascertain the state of the woollen manufactures, previously to the Revolution, other particulars regarding it will be noticed, as well as other places pointed out, where several branches were carried on with success. The above is only a general sketch of it.

In Picardy, it was calculated, that, in the city of Amiens only, they made 129,800 pieces of woollen stuff, besides 50,000 pieces brought from the adjacent parts, for which reason they were called cloths forgerone. The value of the woollen manufacture at this place was computed to amount to nearly 1,600,000 livres annually. The extent and value of the manufactures of Abbeville were little inferior to those of Amiens. At Beauvais, 500 looms were employed in making the two sorts of cloth manufactured there, and 40 fulling-mills; 68,000 pieces of cloth were manufactured of 745,000 pounds.
FRANCE.

Statistics.

Of French wool, and 115,000 pounds of Spanish. The wool grown at this period in the province of Picardy, and used along with Spanish wool in their manufactures, amounted to 284 milliers. In that division of Champagne, which, previously to the Revolution, was called the department of Rheims, there were, made, in the flourishing period of its manufactures, 54,000 pieces of stuff. In this department were included Rheims itself, Sedan, and Vervins. In the generality of Poitiers, principally at Poitiers itself, and Niort, were annually made from 25,000 to 50,000 pieces of stuff; in the Orleánois, about 25,000 pieces of cloth. Roumartin, in this district, already noticed, made nearly 600,000 pieces of stuff.

In Champagne.

In Poitiers.

In Anjou, Ar.

In Brittany.

In Normandy.

In Languedoc.

In French Flanders.

In the provinces of Anjou, Touraine, and Maine, about 18,000 pieces of stuff. In Berry, there were 58 places where cloth and other woollen stuffs were made; seven of which made from 3000 to 4000 pieces each; six from 2000 to 3000; and the rest about 800 or 900 pieces. The tapestry made in this generality amounted to 80,000 livres annually. In Brittany, 800 looms were employed, chiefly in making light stuffs. The principal places, Nantes, Rennes, St Brieux, &c. In Normandy, the woollen manufacture flourished extremely, in the generality of Rouen (that is, a division of the province over which an inspector of the woollen manufactories was placed), there were 12 looms, principally employed in manufacturing cloth, serges, and tapestry. The chief places for cloth were Darental, Eteluif, and Louviers. In the generality of Alençon, another division of Normandy, upwards of 60,000 pieces of cloth, and other drapery, were made; the principal places were Alençon and Aumale, in which latter place 1200 looms were employed in the manufacture of serge. Burgundy, Dauphiny, and Provence, were not very celebrated for their woollen manufactories. There was, however, a considerable manufacture of stockings at Dijon; about 1000 pieces of cloth made at St Jean-en-Royans, and about 6000 pieces at Romans. The manufactories of Languedoc were very important and flourishing. At Lodève, 45,000 pieces, white and grey, were made; at Beziers, Sept, and Carcassone, the manufactories were equally flourishing. In the middle of the last century, the annual product and manufacture of Languedoc, so far as it relates to our present topic, was as follows: sheep 1,000,000 livres; sustians and basins 90,000; blankets 230,000; bargames and tapestry 20,000; woollen stuffs, fine and coarse, 4,100,000; cloths, principally fine, 8,40,000; woollen stockings 40,000; hats 400,000; making a total of 14,300,000 livres. In French Flanders there were also pretty considerable manufactories of woollen goods, of various descriptions. At St Omer's, 350 looms were employed in making cloth, druggets, besides a great many stocking frames. At Lille there were nearly 1000 looms employed in making camblets, besides several hundred in making callimancoes, &c.; and 200 frames in making stockings and caps. Above 300,000 pieces of stuff were made annually at this place. At St Pour, between Marseilles and Toulon, there is a manufacture of red worsted caps, which are very much worn by the peasantry of Provence, and the fishermen of Marsilles. Hence arose the bonnet rouge during the Revolution. It was introduced by the Marseillais as the fashion of their country. To this account a few miscellaneous articles may be added. Carpets were made at Rouen, at Arras, and at Felletin, a small town in the Lower Marche: these were called tapestry carpets; those made at Tournay were called carpets of moucade; tapestry at Arras, as well as the other places mentioned above; blankets in Normandy, Auvergne, and Languedoc; at Darnétal in Normandy, the best and finest; at Vernon, in the same province, of an inferior quality.

Such is a sketch, necessarily brief and imperfect, of the principal branches of the woollen manufactories of France at the period of their most flourishing state. Long before the Revolution, however, many of them had declined to a considerable degree. A few years previous to that event, the woollen manufacture at Carcassone was by far the most important. In 1786, the following is the state and balance of the trade in cloth for exportation to the Levant, manufactured at this place.

They manufactured every year at Carcassone 64,800 pieces of cloth, of which 800 only were sold in the kingdom for home consumption: the remainder exported to the Levant. The whole amount of cloth exported was worth 11,156,000 livres. The greatest part of the wool used in that manufactory was French wool, chiefly from Rouillon and Languedoc. They used a vast quantity of tin and cochineal in their dyeing. The cost of the drugs was estimated at 6 livres each piece of cloth. The price of the 300 bales of wool, each of 300 lbs. imported from Spain to mix with the native wool, came to 270,000 livres. The price of the drugs to 334,000; making a total sum, paid for raw materials from abroad, of 654,000 livres. They sold to the merchants of Marseilles, for exporting into Turkey, to the amount of 11,156,000: Leaving a balance for the workmanship, and the price of the raw materials of the growth of the kingdom, of 10,482,000 livres, or £438,587, 19s. sterling. In 1784, France exported cloth to the value of 15,530,000 livres; stuffs to the value of 7,600,000; and plush, &c. to the value of 4,225,100. The exportation of cloth in the year 1787, had fallen to 14,242,460 livres; and that of stuffs, in the same year, to 5,615,800 livres. The produce of the whole woollen manufactories was rated, in 1789, at 140,000,000 of livres annually.

2. The next manufacture in importance and extent is the silk manufacture; but of the state of this, when it was most flourishing, we cannot collect such details as we have given relative to the woollen manufacture; because, under the old government, the part of the kingdom, where there was any woollen manufacture, was partitioned into several departments, or districts, called generalities, with an inspector to each, and a superintendent over the whole; and thus a particular account of this manufacture might be obtained. We shall, therefore, be obliged to specify the principal places where the silk manufacture is carried on, and afterwards to give such estimates of its value before the Revolution as we can collect. The quality of French silk, and particularly that of Languedoc, is very good. It is made into woof, and even very beautiful organdize. Since the establishment of the silk mills at Vaucanson, the French organdize has obtained a superiority over that of foreign countries. The woof made in Languedoc and at Alais is preferred. The annual export of raw silk from the latter, in the most flourishing state of its trade, was 1,200,000 lbs.

The most considerable manufactories of silk are those established at Tours, Lyons, Nismes, Avignon, Marseilles, and Paris. The silks of Tours and Lyons are esteemed of the best quality: Those manufactured at Nismes are far inferior. Florentine taffetas, English taffetas, and damask, are manufactured at Avignon. There are also silk manufactories at Rouen, Thoulous, Auch, Narbonne, Amiens, and several other places.
The best gold and silver laces are made at Paris and Lyons; and some of inferior qualities at Montmorency, Sarcelles, Estrepagny, &c. Ribbons are chiefly made in Paris and Lyons: There are also large quantities manufactured at St Etienne and St Chamont. Silk stockings, gloves, and mittens, are manufactured at Paris, Lyons, Nismes, Montpellier, Dourdans, &c.

During the most flourishing period of the silk manufacture of Lyons, it is computed that 18,000 looms were constantly and regularly at work, of which about 12,000 were employed in the manufacture of figured silks. The state of the manufacture in 1786 was as follows: There were 2,589,200 raw silks used, of different kinds, independent of the silks of the growth of the kingdom. They imported at Lyons, chiefly by the way of Geneva, raw silks from Piedmont to the amount of 698,480 livres; from Naples, to the amount of 263,490; and they employed native silks to the amount of 447,700; making the total value of the raw silks 1,393,450 livres.

The fourth part of this amount was sent to different parts of the kingdom to be manufactured; the three other parts were employed at Lyons,—which gives an amount of 1,049,661 livres. Upon this computation it results, that they manufactured yearly in that city 349,887 pieces of stuff of all kinds. It was computed, that each piece brought a benefit to the manufacturer of 36 livres, or 12 livres for each pound of silk; which gives 12,595,932 livres. In the year 1787, the manufactures of Lyons employed 15,000 looms; in 1788, 14,777; and the number of workmen was 58,300.

In the most flourishing state of the silk manufacture, it was computed that nearly half the looms of the kingdom were employed at Lyons. There were besides at Nismes about 5000; at Tours from 1200 to 1500; and about 2900 at Paris. There were besides about 20,000 used for the making of silk stockings, and 10,000 for that of ribbons, galloon, and lace. In 1775, an inspector of the manufactures of Languedoc estimated the quantity of native silk in the whole kingdom at 30,000,000 livres. Some years afterwards, however, a much lower estimate and valuation was given, by which it appears that the native silk was worth 56,000,000 livres. The value of the silk manufacture, including all descriptions, was 125,000,000; the raw material of which being of the value of 33,000,000; there remained for wages and profit 42,000,000.

The annual value of the various kinds of silk articles sent out of France were estimated as follows: Silken stuffs, taffetas, satins, &c. 14,884,100 livres; ditto, mixed, 649,000; silk gauzes, 5,432,000; handkerchiefs, 118,000; ribbons, 1,831,500; galloon 2,589,200; various other articles, 445,300; making a total of 25,370,100 livres.

3. Linen is manufactured in most of the provinces, but principally in Brittany, Normandy, Picardy, Hainault, Cambresis, Flanders, Maine, Dauphiny, Auvergne, Beaujolais, Champagne, Gascony, and Anjou. Brittany and parts of Normandy are most celebrated for this manufacture. The principal articles of linen cloth made in Normandy are those called low cloths, made in the vicinity of Fecamp, in the department of the Lower Seine; hemp-tow cloths, made in the valley of Longueville, in the adjacent villages, and near Ronen; cloths used in the formation of oil cloths and umbrellas are made at Ourville; a particular sort of linen, formerly sent to the Brazils, at St George's; toiles a veste in the vicinity of Bascqueville; strong flaxen cloths at Dieppe, Havre, Fecamp, &c.; tickings at St Loo, Evreux, and other parts in Lower Normandy; coverings for mattresses at St Valery, St Laurent, &c.; linen cloth with blue and white grounds, for sailors' shirts, at St Laurent, Toqueville, &c.; damasked linens at Rouen, St Valery, and Bolbec; in the article of printed linens only, the sale at Rouen, when the manufacture flourished, was computed at from £20,000 to £25,000 sterling per week. The quantity sold in the hall annually, averaged about 35,000,000 millions of livres. The principal linen manufactures of Brittany are sailcloth and canvass at Rennes, Angers, Agen, (also at Marseille and Mont de Marsan,) and what are called Crez et Bretagnes. In the middle of last century, 6000 bales of Crez and Bretagnes, were annually exported from Marsilix alone; 20 years afterwards the exportation fell to about 4500 bales; and at the commencement of the Revolution it fell below 4000. The annual value of these cloths made in Brittany, in the flourishing state of the manufacture, was about 1,200,000 livres.

In several of the villages of this province, particularly at Vitry, the women and children used to be much employed in knitting thread stockings and gloves, which were sent to Spain, and even to the East Indies. They sold about 20,000 livres worth of them every year. Before the Revolution, France exported linen cloth to the amount of from 12,000,000 to 13,000,000 livres; and lawn and cambric, manufactured principally in the French Netherlands, to the amount of 6,000,000.

4. Though the cotton manufacture is of comparatively late establishment, yet it had begun to flourish considerably before the Revolution. The principal scene of it was then, and indeed still is, Rouen and its vicinity, which has not inaptly been called the Manchester of France. Here cottons, made from materials called tuctolin, brought to France by way of Holland; cotton handkerchiefs; a sort of coarse cotton cloth, called stamnose; besides fabrics of mixed cotton and thread, were manufactured. There were also small manufactures of cotton goods in some other parts of France, at the period of the Revolution, particularly in Beaujolais, Languedoc, and Flanders; but we are not acquainted with any data on which to estimate the value of this manufacture. The quilts of Marseilles, which are still as much in use as ever in that part of France, where a blanket is a rare thing; the muslins of Rouen, Nismes, Bezieres, and Rheims; and the dimities and futians of Alençon, Lyons, Troyes, and Toulouse, may be classed under this head.

5. As the laces manufactured in France are made Laces, both of silk and thread, we shall consider them separately. Before the Revolution, they were a flourishing and important branch of trade. They are manufactured at Lisle, Vaucavilles, Dieppe, Puy, Paris, Caen, Arwas, Alençon, and Argentan, in the greatest quantity, and of the best quality. At Paris are made black and white laces of thread; and also at Vaucavilles, Dieppe, and Puy. At Arwas, milanette and entoilage laces, great quantities of which were used to be brought to England. The point lace of Alençon has long enjoyed a great reputation through France, England, Germany, &c. The point lace of Argentan, called point d'Argen-

6. In the beginning of the last century, there were seven provinces in France where the paper manufacture was chiefly carried on: Champagne, Normandy, Brittany, Angoumois, Perigord, Limousin, and Au-

vol. ix. part ii.
imported a great deal of paper from France; towards the middle of that century, however, the paper trade of France declined, in consequence of these countries making paper nearly sufficient for their own consumption. Previously to the Revolution, the chief paper manufactories of France were at Ammonay, in the department of the Ardche, very fine paper is manufactured there; at Montargis, in the department of the Loiret; at Esone, Courtalin; Ramberviller, in the department of the Vosges: Besancon, Ornain, Villafaut, Arbois, Arches, Archettes, and St Bresson. The total number of manufactories before the Revolution was about 200. Three classes of white paper for writing and printing are made; each class is divided into eight or ten different sorts: different colored papers and pasteboards are also made; and paper hangings, executed with considerable taste, at Paris. Before the Revolution, the paper manufactured in France amounted to the annual value of 8,000,000 livres; 1,350,000 of which were exported to foreign countries, and 350,000 to the colonies.

7. The best hides are those of the oxen of Avergne, Limosin, and Poitou. Leather is prepared at Bayonne, Lectoure in the department of Gers, and St Germaine. The best tan-yards are at Paris, Dijon, Troyes, Coulommier, Rheims, Mezieres, Luon, Soissons, Rouen, Caen, Bayeux, Vcmeuil, Perche, Chartres, Orleans, Tours, and Beauvais: leather for harness is manufactured at Nemours, and Louviers. Goat skins are prepared at Paris, under the name of maroquin. Chamois leather is made, or imitated, at Niort, Strasbourg, Grenoble, Amnonay, &c. Buffalo hides are also manufactured in France; and parchment in Poitou, Languedoc, Flanders, Alsace, and at Paris. The parchment made in France is esteemed the best in Europe, and in time of peace is frequently imported into this country.

8. Hats are chiefly manufactured at Lyons, Marseilles, Rouen, and Paris. Before the Revolution, considerable quantities were exported to the French colonies, and also to Spain and Spanish America, by the way of Cadiz; at that time, there were about 70 hat manufactories in the kingdom.

9. Nails are made in almost every province in France; but the most considerable forges are in Normandy, Champagne, and Limosin: at Limoges, great nails of particular quality, particularly for horse shoes, were made, and sent to Paris, previously to the Revolution. Pins and needles are made at Paris, Rouen, Bourdeaux, Limoges, Evreux, and Aigle. Cutlery at Montargis, Chateaurault near Poitiers, where it is made with scarcely any division of labour, being in the hands of distinct and unconnected workmen, who go through every branch on their own account, and without assistance, except from their families; at Cosne, Moulins, &c. Steel is chiefly manufactured at Amboise, where it was established by the Duke de Choiseul; at St Etienne, Colmar, and Grenoble. Works in bronze and or-moulu are carried to great perfection in Paris. Clocks and watches are made in different parts of France, particularly at Paris, Cluse, and Carouges; the coarse movements are made at Dijon and its vicinity. The number of watches sold annually in France, before the Revolution, was supposed to be 200,000. At Paris and Lyons, at the same period, 70,000 workmen were employed in the manufacture of jewellery; in the capital, every article of this kind, as well as all kinds of expensive and tasteful toys, are carried to great perfection. A few years before the Revolution, the art of casting cannon solid, and then boring them, was introduced by W. Wilkinson, who established a manufactury for that purpose, in an island in the Loire below Nantes.

10. China is principally manufactured at Sevres, China, where it has long been carried to a high degree of perfection. Several manufactories of earthen ware, chiefly of the coarse kind, are carried on at Aubagne and other places; imitations of our Staffordshire ware are made at Chantilly and Paris; they are called terre de pipe; stone-ware is made at Moulins, and delft at Marseilles.

11. The glass manufacture of St Gobins still retains its pre-eminence for large and beautiful mirrors; there are also glass manufactories at Moulins; at Baccarat in Lorraine, where three kinds were made, plate-glass, common glass for windows, and table-glass, the wood used in this manufacture amounted to between 8000 and 10,000 cords; it was brought down the Meurthe, and in other parts of the kingdom. A considerable trade in curious works of enamel was carried on at Nevers before the Revolution.

12. Under this head we shall notice all the principal remaining manufactories of France, which flourished previous to the Revolution. Soap of the first quality is made at Marseilles, where, and at Paris, great quantities of wash balls were also made: inferior soap was manufactured at Toulon, Bourdeaux, Rouen, Lisle, Abbeville, Amiens, and St Quintin. The amount of this manufacture was 60 millions, only two of which were exported. The principal manufacture of starch is at Paris. The manufacture of tobacco and snuff amounted to 22,000 cwt. of the former, and 2000 cwt. of the latter. Verdeligris, chiefly at Montpellier; alum and Epsom salt in the neighbourhood of Mezieres; Glauber salts, which are esteemed of excellent quality in the provinces bordering on the Mediterranean. The refining of sugar was principally carried on at Marseilles and Nantes. Cables and ropes at Brest, Rochefort, Toulon, Abbeville, Dunkirk, and Havre de Grâce. Bleaching is carried on to a great extent in Picardy, principally in the vicinity of St Quintin. Dying of course is carried on at the seats of the principal silk, woollen, linen, and cotton manufactories. The waters of the Saone are excellent for scouring, containing, it is said, a soapy quality; those of the Rhone, from their purity, are equally adapted for dyeing; the waters of the little river Sornin are also reckoned remarkably good for dyeing; and it is generally supposed that the superior excellence of the French cloths, with respect to colour, especially with respect to black, results in a great measure from the purity of the waters which are used in dyeing.

111. A revolution, such as that which for upwards of 25 years has afflicted and depressed the political and moral state of France, could not fail to press very severely on her manufactories. Most of them have suffered in a very great degree; others have passed through the trial not so much hurt; and some appear even to have been extended and improved during the Revolution. Of course, those suffered most which principally depended on foreign demand; for the commerce of France being in fact annihilated, the articles of home manufacture, which supplied that commerce, no longer being in equal demand, were no longer made in equal quantities. Another cause of the decline of the manufactories, especially during the last years of Bonaparte's reign, must be sought for in the conscription, which, in many instances, absolutely strips the manufactures of
nearly all their workmen. But though the general fact is sufficiently well established, that the manufactures of France are at present, almost universally, far inferior to what they were previously to the Revolution; yet the precise degree of deterioration cannot be ascertained, and even with respect to the most important of them. We shall therefore be under the necessity of confining ourselves to a few brief and unconnected notices on this point.

The silk manufacture seems to have suffered the most. The number of looms employed at Lyons in 1788, has been already stated at 14,777. In 1801, according to Peuchet, author of the Statistique de la France, there were but 7000 looms, and many of them were unemployed. The exposition of the French government rates them at nearly the same number in 1814. The woollen manufactures of Carcassonne were languishing previously to the Revolution; and that event has still further depressed them. Mr Birkbeck visited the fine cloth manufacture of Louviers, in 1814. He represents the establishment there for spinning woollen yarn as being on a large scale; and mentions that their cropping or shearing machines were performing their office with great rapidity. The manufacturers, according to him, are all wide awake to mechanical improvements. Hence it would appear, that whatever injury this important manufacture may have suffered from the Revolution, with respect to the demand for its goods, it has been advancing in improvements during that time. The cotton manufacture undoubtedly has extended during the last 25 years; though, by the immense drain on the population which Napoleon's wars with Russia, and from that period till the peace of Paris, occasioned, it has latterly been in a declining state. Probably the scarcity and the enormous price of the raw material also contributed to their depression. Mr Birkbeck visited a cotton mill at Deville, near Rouen, which employs 600 people; and he describes the machinery as good. Indeed, it is well known, that all the inventions and improvements in the cotton machinery with which we are acquainted, are used in the French manufactories at Rouen. Cotton manufactures have lately also been established at Lille, in French Flanders; and it is worthy of remark, that the same complaint is made with respect to the influence of this manufacture on the morals of the work people, as has long been made in this country. The linen manufacture of Brittany, and the manufacture of stuff and tobacco which is carried on there, especially at Morlaix, have suffered greatly during the Revolution. The Gobelins manufacture began to decline before that event; tapestry was not so much in fashion; and that branch of it which was confined to the dyeing of scarlet cloth, is now almost entirely at an end, in consequence of cloths of that colour being very little worn in France, and the Swiss regiments, the officers of which formerly consumed vast quantities of cloth dyed of the Gobelins scarlet, being no longer employed. We shall conclude this chapter with a brief enumeration of those manufactures which at present are the most important in France. Mineral acids at Paris, Montpellier, and Rouen. Alum at Paris and Montpellier. Baracces, for lining pelisses, at Lisle, Amiens, and Valenciennes. Damasks, (saddar,) at Troyes, Lyons, Toulouse, Chaillot, and Alençon. Lawn and cambrics at St Quentin, from which place formerly there were exported to Russia annually a million pieces, and Cambray, Russian blue at Paris. Silk hosiery at Paris, Lyons, Nimes, Montpellier, Ganges, and Douard; worsted hosiery in the departments of the Aisne, and of the Somme, and particularly at St.-terre. Cotton hosiery at Rouen, Troyes, Arcis-sur-Aube, and Sens. And in the departments of the North, and of the Maine and Loire, thread stockings are manufactured. Sweetmeats at Paris, Rouen, Tours, Orleans, Dijon, Sedan, Bourdeaux, &c. Cotton velvet at Amiens. Muslin, and other cotton goods, at Rouen. Cutlery at Paris, Monlins, Langres, Chatellerault, Thiers, Lisle, &c. Crapes at Lyons and Avignon. Gold and silver lace at Paris and Lyons. Silk lace at Fontenai, Purseaux, Louvre-en Parisis, Saint Denis, Montmorency, Gisors, &c. Lace made of flax, at Lisle, Valenciennes, Charleville, Sedan, Besançon, Dieppe, Havre, Caen, Puy, Arras, &c. At Dieppe, about 4000 women, chiefly wives and daughters of the seamen and fishermen, are employed in this manufacture; and at Puy about 6000. Cloth at Abbeville, Elbenf, Louviers, and in Languedoc. Brandy at Bourdeaux, Rochelle, Cognac, the department of the Charente. Isle of Rie, Orleans, Blois, Poitiers, Angers, Tours, Nantes, &c. Imitations of Holland's gin at Calais and Boulogne. Artificial flowers at Paris and Lyons. Gloves at Paris, Vendôme, Grenoble, Avignon, Blois, Montpellier, Grasse, &c. Olive oil in the departments of the mouths of Rhone, of the Gard, Var, &c. Serges at Aigale, Seine-valley, Gournay, Auxerre, Sedan, Abbeville, Beauvais, &c. Liques at Montpellier and Rouen. Writing and printing paper at Angouleme, Montargis, Amnon, &c. Stained paper at Paris and Lyons. Perfumery at Montpellier, Grasse, Lyons, and Paris. Porcelain at Sevres and Paris. Ribbons adorned with gold and silver at Paris and Lyons. Other ribbons at Paris, Lyons, Tours, St Etienne, St Chamont. Ferret-ribbons at Amiens and other places in Picardy. Ribbons made of flax at Amberg. Silks at Nismes, Lyons, Tours, &c. Silk and cotton stuffs at Rouen. Tapets at Lyons, Nismes, Avignon, &c. Carpets at La Savonnerie, Aubusson, Beauvais, Rouen, Arras, Felletin, &c. Linen cloth at Rouen, and other parts of Normandy, Brittany, Couray, Arras, Beauvais, Conquegnis, St Quentin, Noyon, Peronne, &c. Velvets at Lyons. Velour at Montpellier. Vinegar at Orleans, Blois, Angers, Nantes and Paris. Glass at St Gobins.

CHAP. VI.

Commerce—Shipping—Coasting and Inland Trade—Fisheries—Total Produce of all kinds of Industry.

As the commerce of France has been nearly annihilated by the Revolution, we shall give a statement of it at the commencement of that event; and, in order that some estimate may be formed of its previous progress, we shall prefix a statement of it as it existed at the end of the reign of Louis XIV.

I. The importations from Spain into France, at the end of the reign of Louis XIV., amounted to the value of 17,600,000 livres. Of this value, a great part consisted in specie. There were three methods principally, by which the French, at this period, obtained part of the money or precious metals, which the Spanish vessels brought from their South American possessions. In the first place, French merchandise was carried to Cadiz, and exported thence in the galleons; in the second place, the productions and manufactures of France found a ready and extensive sale in Spain; and, lastly, the inhabitants of Auvergne, Limousin, and Gascony, annually went into Spain, where they assisted in the
harvests, or in other occupations, and returned, when they had obtained a competency, into their own country. At the period of the Revolution, the imports from Spain into France amounted to the sum of 33,300,000 livres in merchandise alone, without counting piasters, &c. to the amount of 62,500,000 livres. The imports from Spain, at this period, consisted principally of anchoves, olive oil, cocoas, almonds, lemons, oranges, raisins, brandies, luscious wines, chinchona, saffron, jasap, liquorice, dyewoods, inlaid work, ashes, iron, copper, wool, silk, leather, hides, skins, indigo, cochineal, alum, vermiilion, beasts of burden principally mules, silk handkerchiefs, toys, jewellery, household goods, and clothing for the marines. This value of 33,300,000 livres may generally be arranged into the following classes: 1. Raw materials, principally wool, ashes, and beasts of burden, to the value of 20,000,000; 2. Estables, as well animal as vegetable, to the value of 7,000,000; 3. Wines and liquors, to the value of 4,000,000; and 4. upwards of 2,000,000 in manufactured articles.

The exportations from France to Spain, at the end of the reign of Louis XIV. amounted to the sum of 20,000,000; at the period of the Revolution, they had increased to the sum of 44,400,000 livres. In this latter period, the exports chiefly consisted of the following articles: grain, vegetables, flour, cod, salted fish of other kinds, provisions of various descriptions, brandies, wines, sheep, mules, pigs; cinnamon, pepper, sugars of all sorts; pitch, tar, wool, cotton, silk stockings, hats, laces, woollen cloths, stuffs, handkerchiefs, gauzes, ribbons, linen, leather and skins, books, stationery, mercery, ironmongery, household goods, woollen works and metals. The manufactured articles amounted to the value of 26,500,000 livres; the raw materials, and beasts of burden, about 5,200,000 livres; the estables about 11,000,000; and the wines and liquors about 1,500,000 livres.

II. The importations into France from Portugal, at the end of the reign of Louis XIV. amounted to the trifling sum of 340,000 livres, and consisted chiefly of hides in the hair, Brazil tobacco, olive oil, and dried fruits. At the period of the Revolution, the value of the imports had increased to the sum of 10,400,000 livres. They consisted chiefly of olive oil, cocoa, lemons, oranges, sweet wines, cinnamon, pepper, cloves, cotton wool, ivory, undressed goat skins, indigo, dyewoods, inlaid work of the East and West Indies, India cotton, and Brazil tobacco. The exportations from France into Portugal, at the end of the reign of Louis XIV. amounted to the sum of 740,000 livres, and consisted of woollen goods, linen goods, earthen ware, paper, &c. At the period of the Revolution, the exportations amounted to the sum of about 4,000,000, and consisted chiefly of grain, vegetables, hams, cotton, woollen stuffs and stockings, laces, ribbons, paper, skins, hides, mercery, glass, books, &c. The manufactured articles amounted to about 2,300,000 livres; the raw produce and provisions to about 1,600,000 livres.

III. The importations from France into Italy, Piedmont, Savoy, and Switzerland, at the end of the reign of Louis XIV. amounted to the sum of 10,700,000: at the period of the Revolution, they had increased to 82,000,000, and consisted chiefly of corn, rice, vegetables, flour, olive oil, lemons, oranges, raisins, figs, cheese, lemon juice, liqueurs, mauna, opium, senna, fresh fish, silk, goats and camels hair, hares wool, wood for fuel, ashes, sulphur, alum, galls, stumac, tartar, saffron, indigo, cochineal, lac, silk, stuffs, gauzes, perfumery, essences, mercery, hardware, ribbons, white and coloured cottons, muslins, linen, and sackcloth. These importations may be divided into three classes: 1st, Manufactured articles to the amount of 16,500,000 livres; principally the silk ribbons of Padua, the eraps of Bologna, the stuffs and silk velvets of Genoa and Florence, and more especially the white and coloured cottons of Switzerland: 2d, Raw materials to the amount of 37,400,000, of which upwards of two thirds was of raw silk: 3d, Estables to the amount of 28,300,000, of which 11,500,000 was for olive oil employed in the manufacture of fine soap at Marseilles and other places.

The exportations from France to these countries, at the end of the reign of Louis XIV. amounted to the sum of 23,400,000. At the period of the Revolution, they had increased to 78,500,000, and consisted principally of rye, cod, oil, wives, brandies, oxen, sheep, pigs, goats, coffee, and other West India produce, copper, lead, cotton. raw and spun, dye woods, inlaid wood, salt petre, linseed, gun, red lead, copper, stockings, hats, woollen cloth, laces, gauzes, handkerchiefs, ribbons, linen cloth, leather, skins, mer- ceries, millinery, hardware, toys, jewellery, soap, glass. They may be divided into five classes: 1st, Manufactured articles to the amount of 30,800,000 livres: 2d, Raw materials, or such as had undergone only the first preparation, as cotton thread principally for Switzerland, to the value of 11,800,000 livres; 3d, Estables to the value of 10,700,000 livres: 4th, Wines and liquors 5,000,000; and 5th, Colonial produce 20,000,000.

IV. In 1686, the actual value of the importations from England into France, amounted to 18,000,000 livres; viz. 8,400,000 of manufactures; 6,300,000 raw materials; and 3,200,000 in other articles. At the end of the reign of Louis XIV. the importations from England into France, amounted to the sum of 13,876,000 livres; viz. 6,000,000 in woollen and cotton goods, prepared skins, earthenware, and other manufactu- res; 4,100,000 in metals, coal and horses; 3,700,000 in estables, &c. At the period of the Revolution, they amounted to about 58,500,000 livres; and consisted principally of butter, salted meat and fish, colonial produce, corn, flour, rice, coal, copper, iron, lead, pewter, woolen goods, cotton goods, hardware, earthenware, leather, ivory, whalebone, alum, copperers, white lead, horses, leaf tobacco,tablename, glass, &c. They may be arranged under three classes: 1st, Manufactured articles to the amount of 33,100,000 livres; 2d, Raw materials, particularly the metals, and coal, 16,400,000 livres; 3d, Estables, &c.

In 1686, the exportations of France into England amounted to 23,300,000 livres; viz. 1st, Manufactures to the value of 11,700,000; 2d, Raw materials about 2,000,000; and 3d, Estables, wines, liquors, &c. 9,600,000. At the period of the end of the reign of Louis XIV. the exportations had greatly declined, not amounting to more than 18,000,000; viz. 12,000,000 of silk goods, cumbries, laces, &c.; 1,000,000 in raw materials, principally leather, cochineal, and indigo; and 5,800,000 in estables, wines, liquors, &c. The exportations from France into Great Britain and Ireland at the period of the Revolution, amounted to about 38,000,000; consisting principally of plums, salt, wines, brandies, treacle, cotton, indigo, Spanish wool, laces, cumbries, lawns, glass, perfumery, gloves, millinery, vinegar, oils, cork, toys, jewellery, &c. They may be divided into four classes: 1st, Manufactured articles to the value of 7,300,000 livres; 2d, Raw materials 11,100,000 livres, of which two-thirds consisted of cotton from the French
England and France.

Statistics.

West India islands; 3d, Wines, liquors, &c. 13,500,000.

Between France and Holland.

The imports from Holland into France, at the end of the reign of Louis XIV, amounted to about 12 millions; viz. 2,500,000 manufactures; 4,700,000 raw materials; and 4,800,000 cattles, &c. At the period of the Revolution, they amounted to about 32,100,000; and consisted of corn, salted provisions, cod, salmon, cheese, butter, spices, Geneva, beer, wood, dye woods, ashes for manure, copper, ivory, steel, brass wire, lead, tallow, flax, linseed oil, skins, hogs bristles, madder, red and white lead, tobacco, linen cloth, paper, and hardware. They may be arranged as follows:

- 5,500,000 manufactured articles;
- 15,000,000 raw materials;
- 12,000,000 for provisions and liquors.

The exportations from France into Holland, at the end of the reign of Louis XIV, amounted to 30,700,000; viz. 2,900,000 manufactures; 6,000,000 raw materials; 22,500,000 in wines, liquors, colonial produce, &c. At the period of the Revolution, the exportations to France amounted to about 49,000,000; consisting of colonial produce, corn, honey, rice, wines, brandies, plums, jujupi berries, hops, tar, wool cards, Spanish wool, tobacco, galls, ocher, wood, turpentine, raw cotton, wax,瑟, raw sugar, pepper, paper, soap, glass, lead, gloves, millinery, &c. It may be divided into five classes:

1st, 6,700,000 manufactured articles; 2d, 7,100,000 raw materials; 3d, 3,200,000 wines, brandies, &c.; 4th, 23,000,000 colonial produce, particularly sugar and coffee; and 5th, 5,600,000 cattles, &c.

VI. At the end of the reign of Louis XIV, the importations from Germany, the Austrian Netherlands, Poland, and Prussia, into France, amounted to the sum of 49,000,000, principally in three classes: 1st, 3,500,000 manufactures; 3,000,000 raw materials; and 9,300,000 cattles, &c. At the period of the Revolution, the importation from these countries amounted to about 51,000,000; viz. about 31,000,000 for manufactured articles, principally the stuffs and laces of Flanders, and the tapes, linens, mercery, and hardware of Germany; 19,000,000 for raw materials, principally coal from Austrian Hainault, hemp and flax from Flanders, brass ware and potash from Germany, Poland, and Prussia; 15,700,600, principally for the horses and cattle of Germany and Flanders. The exportations from France to these countries at the end of the reign of Louis XIV, amounted to the sum of 14,100,000 in three classes: 1st, 5,100,000 of manufactures; 2d, 2,000,000 of raw materials; 37,000,000 of cattles, wines, liquors, &c. At the period of the Revolution, the exportations amounted to the sum of 55,600,000 livres, and may be divided into five classes: viz. 1st, 59,100,000 livres for manufactures of various sorts, especially silk stuffs, embroidered with gold and silver, for the different princes in Germany, and the rich nobility of Poland, lawn and woolen stuffs for the hereditary possessions of the house of Austria in Germany and Flanders; 2d, 12,900,000 livres in raw materials, principally wool and coal, a re-exportation for Austrian Flanders and Germany; 3d, Upwards of 10,000,000 in wines, brandies, and vinegar, for Germany, Poland, and the Prussian ports of the Baltic; 4th, 22,000,000 of colonial produce, particularly sugar and coffee, for the states of Austria and Germany, and the Prussian ports in the Baltic; 5th, 11,000,000 in vegetables and animals for Flanders and Germany.

VII. At the end of the reign of Louis XIV, the importations into France from Hamburg, Bremen, Lubeck, Dantzic, Denmark, Sweden, and Russia, amounted only to 300,000 livres, and consisted principally of timber, hemp, iron, and other metals. At the period of the Revolution, these importations amounted to 31,600,000 livres, and may be divided into three classes: viz. 1st, About 5,000,000 of manufactured articles, principally those manufactured of flax and hemp, and India muslins, brought by the Danes from their possessions in the East Indies; 2d, 24,000,000 of raw materials, particularly copper and lead, through the Hanse towns, timber from Russia and Denmark, iron, pitch, and tar from Sweden, and hemp and tallow from Russia; 3d, 1,800,000 livres, principally for dried and salted fish from Denmark and Sweden. The exportations from France into these places at the end of the reign of Louis XIV, amounted to the sum of 6,800,000; viz. about 856,000 in woollen and linen goods; about 450,000 in copper, cork, &c.; and about 5,400,000 livres in cattles, wines, liquors, &c. At the period of the Revolution, the exportations from France to all these places, amounted nearly to the value of 80,000,000, and may be arranged in five classes: viz. 1st, 3,000,000 in textiles, and manufactures, chiefly for the Russian market and the Hanse Towns; and a small quantity for Sweden and Denmark; 2d, About 71,000,000 in raw materials, particularly indigo, and other drugs for dyeing and cooking, for the Hanse towns, Sweden, and Denmark; 3d, About 12,000,000 in wines, brandies, &c.; and about one-half of this went to the Hanse towns, about a fourth each to Denmark and Russia, and only about one-eighth to Sweden; 4th, About 2,000,000 in vegetables, minerals, and animals; and 5th, About 55,000,000 in sugar and coffee from the French West India islands; of which 47,000,000 was sent to the Hanseatic towns, threes-fourths for Hamburg, and the remainder in nearly equal proportions to Sweden, Denmark, and Russia.

VIII. The commerce between the United States of America and France, owes its existence entirely to the rupture between them and Great Britain, which terminated in their independence. During the three years after the treaty of amity and commerce between the United States and France, concluded in January 1778, the importation from them into France averaged annually the sum of 2,460,000 livres, viz. 136,000 in iron and dried cod; 357,000 in wines, brandies, &c.; 130,000 in other raw materials; and 1,900,000 in leaf tobacco. The exportations from France at this period amounted to 3,000,000; viz. 191,000 in spiceries; 79,000 in wines and liquors; 53,000 in raw materials; and 2,900,000 in manufactured goods, particularly woolen cloths, linen, silk, cotton velvet, hosiery, hats, mercery, earthen ware, East India goods, copper utensils, and warlike stores. The importations from the United States to France, from 1781 to 1783 inclusive, averaged 3,494,000 livres; viz. 60,000 in rice and salted cod; 192,000 in raw materials; and 3,233,000 in leaf tobacco. The exportations from France at the same period amounted to 11,500,000 livres, and may be arranged under four classes: 1st, About 825,000 livres in provisions and groceries; 2d, About 437,000 in wines, brandies, &c.; 3d, About 378,000 in raw materials; 4th, About 9,800,000 in manufactured articles, principally of the same description as those exported during the former period. Taking the average of the three years which preceded the French Revolution, the importations from the United States into France amounted annually to 9,600,000 livres, and may be arranged under four heads: viz. 1st, About 600,000 in rice, and other articles of food; 2d, About 900,000 in raw materials; 3d, About 700,000 in fish; and 4th, About
X. The commerce between France and China was established in 1694. At the end of the reign of Louis XIV., the French possessions in the East were few, and of little moment; consisting only of some country houses at Pondicherry, Surat, and Mazulipatan; an establishment at Canton, and a third at Bandar Abbas, in Persia; but there was so little trade, that, between 1699 and 1719, not more than one or two vessels were annually employed in it; their cargoes, however, must have been valuable, since, at the end of the reign of Louis XIV., the imports from the East Indies amounted to 6,300,000 livres, consisting principally, 1st, of pepper and coffee, to the value of 2,757,000; 2d., of muslin, 2,790,000; and lastly of gold in ingots, 400,000 livres. The exports from France to Asia, at the same period, amounted to 2,852,000 livres, of which there were 2,173,000 in piasters, 542,000 of wrought coral, and 107,000 in metals, &c. At the period of the Revolution, the cargoes brought from Asia into France were valued at 34,700,000 livres, on the average of 1785, 1786, and 1787, consisting, 1st., of manufactured commodities, such as plain and printed cottons, muslins, handkerchiefs, malacca, and silken stuffs, to the value of about 26,600,000 livres; 2d., of cinnamon, pepper, tea, and Mocha coffee, to the value of 6,000,000; 3d., of pearls, coral, raw silk, ivory, &c. to the value of 1,150,000 livres; 4th., of porcelain, fans, and shells, to the value of 492,000 livres; and, 5th., of drugs and dye-woods, to the value of 307,000 livres. The exports from France to Asia, at the same period, amounted to 17,400,000; and consisted, 1st., of 15,253,000 livres, in piasters; 2d., of manufactured articles, to the value of 654,000 livres; 3d., of wines and liquors, to the value of 745,000 livres; 4th., of wood and metals, to the value of 700,000; and, lastly, of various other articles, to the value of 72,000 livres.

XI. At the end of the reign of Louis XIV., the imports into France, from the western coasts of Africa, amounted to about 500,000 livres, chiefly in gums, elephants' teeth, hides, &c.; the number of slaves annually bought was about 2000. The merchandise exported from France, at this period, to this part of Africa, amounted in value to about 650,000 livres. At the period of the Revolution, the exportations for the western coasts of Africa, amounted to 18,000,000, of which nearly 10,000,000 consisted of foreign commodities re-exported; and about 8,000,000 of the produce or manufactures of France. The importations, on an average of 1785, 1786, and 1787, from this part of Africa, amounted to about 1,400,000 livres, in gums, elephants' teeth, and hides principally. At this period about 50,000 slaves were annually bought. No trade was carried on to the isles of France and Bourbon, previously to the year 1735, when La Bourdonnais was sent out as governor. At the period of the Revolution, the exportations from France to these islands amounted to 4,600,000 livres, chiefly in metals, wood, wines, brandy; and some manufactured gowns, cloths, and gilt toys. The returns amounted to 2,700,000, principally in Bourbon coffee.

XII. The importations into France, from their West between India and North American possessions, in the reign of Louis XIV. amounted to 16,700,000 livres, viz. 11,000,000 in sugar and chocolate; 4,081,000 in indigo; 775,000, in cotton, hides, skins, &c.; and 990,000 in tobacco. The exportations from France, at the same period, amounted to about 9,000,000; viz. 4,160,000 in manufactures; 1,500,000 in provisions; 1,501,000
in wines, brandy, &c.; and about the same amount in timber for building, metals, &c. At the period of the Revolution, France received from her West India and American possessions, about 185 millions; viz. from about 134,000,000 in sugar and coffee alone; 2d, about 26,000,000 in cotton; 3d, about 11,600,000 in indigo, and other drugs for dyeing; 4th, about 10,000,000 in cocoa, chocolate, ginger, &c. The exports from France, at this period, were about 77,000,000 livres, which may be arranged in five classes; 1st, 42,447,000 in manufactured goods; 2d, about 19,611,000 in flour, pulse, salted provisions, cheese, &c.; 3d, about 7,885,000 in wines and brandy; 4th, about 6,518,000 in wood, metals, &c.; and, lastly, about 2,057,000 in articles of less importance.

It must be obvious, that perfect accuracy respecting the value of the particular or total exports and importations cannot be obtained; we need not, therefore, be surprised to find them estimated differently by different authors. According to some, the exportation in 1787 amounted in all to 542,604,000 livres; of which, 311,472,000 were the raw produce of the soil, metals, &c.; and 221,183,000 the produce of French manufactures. Arnould, author of the treatise De la Balance du Commerce de la France, is of opinion, that, about the same period, the value of the exports of the produce and manufactures of France was 364,000,000, which he supposes to be thus divided among the different parts of the kingdom. The maritime districts partook to the amount of 228,000,000; the frontier districts to the amount of 77,000,000; the interior districts only to the amount of 11,000,000; the cedevent generality of Paris, to the amount of 18,000,000; and the district round Lyons, preponderating the department of the Rhone and the Loire, to the amount of 29,000,000.

The imports of France, upon an average of the years 1785, 1786, 1787, are calculated at 611,008,200 livres. In 1792, the average imports amounted to no more than 319,000,000, according to the report of Roland to the Convention. By an official report laid before the Consuls, 22d September 1800, it appears, that the value of the imports was 325,116,400 livres; of which, 114,190,100 was in provisions, liquors, &c.; 123,501,500 in raw materials; upwards of 35,000,000 of this being cotton wool, and 29,265,500 was in foreign manufactures. The exports that year amounted to 271,575,600; of which, 87,562,500 consisted of provisions, wines, liquors, &c.; 33,699,500 of raw materials; and 149,854,200 of manufactured goods; of these last, the silk amounted to 41,222,000, the linen and hempen cloth to 34,856,000, the woollen drapery to 23,146,000, and the cotton stuffs to 12,335,000. In the same year, the imports from Spain were valued at 64,446,500; the exports to Spain at 62,441,400: The imports from the Batavian republic at 50,783,500; the exports at 57,751,600: The imports from the Ligurian republic were 26,501,600; the exports 25,010,700: The imports from the Helvetic republic 17,008,600; the exports 38,809,100. Making the total imports from friendly and allied powers 188,505,000; and the total exports to them 162,012,800. The total imports of neutral powers were 84,783,300; of which, upwards of 82,000,000 were from Denmark, Sweden, Prussia, and the Hanse towns; and only about 2,000,000 from the United States. The exports to the same powers were 53,527,400; of which, only 557,700 were to the United States.

There are no data on which an estimate of the number or tonnage of the French shipping, at the end of the reign of Louis XIV. can be formed; but in 1669, Colbert reckoned that France employed only 600 in foreign commerce; and it is supposed, that at the beginning of the 18th century this number had not increased to much above 800 vessels, of from 100 to 120 tons burden. If this latter supposition be correct, they must have declined in the middle of this century; for the anonymous author of a pamphlet, entitled the Present State of the Revenue and Forces of France and Spain, compared with those of Great Britain, 1740, asserts, that in France there were not then more than 600 sail of merchant ships at the most, of all sizes; and that, reckoning 25 sailors to each, one with another, all the seamen of France did not exceed 30,000, including 11,000 seamen classed by the king, who had leave to serve aboard the merchant ships, till they were wanted for the king's service. At the period of the Revolution, the number of ships employed in long voyages, either to the East and West Indies, or to the whole and cod fisheries, amounted to 1000, averaging 250 tons each. The exports to different countries in France employed, at this period, about 580,000 tons; of which, little more than one-fourth, or 122,000 tons, were French. In 1792, an official report was made by Roland to the National Convention; from which it appears, that in that year there entered into the ports of France, 7607 vessels, amounting to 693,255 tons; of which, 1823 vessels, or 147,821 tons, were French; 1940 vessels, or 145,012 tons, were English; and 334 vessels, or 346,402 tons, belonged to other nations; and in the same year there cleared outwards 6618 vessels, amounting to 54,935 tons; of which, 1940 vessels, or 147,410 tons, were French; 3111 vessels, or 90,662 tons, were English; and 3307 vessels, or 306,626 tons, belonged to other nations. From an official report laid before the Consuls in 1800, it appears, that at that time the total number of ships employed in foreign commerce, that entered inwards, amounted to 7581, or 275,177 tons; of which, 2975 vessels, or 98,304 tons, were French; the rest belonged to foreigners: That the number of vessels cleared outwards, amounted to 8696, or 512,907 tons; of which, 3353 vessels, or 104,687 tons belonged to France. That the coasting trade between the ports of France employed about 26,000 vessels, (including repeated voyages,) or about 700,000 tons, nearly the whole of which were French. The colonial and fishing vessels entered inwards were 71, or 4769 tons; and cleared outwards, 296 vessels, or 10,000 tons.

The coasting and inland trade of France, before the Revolution, were both very considerable; indeed, it has been calculated, that the bringing the products of the south parts of France along the coast, to those of the north, for the supply of the capital, and the northern provinces, constituted a coasting trade only inferior in magnitude to the coal trade of England. The ships loaded at Bordeaux, with wines and fruits of all sorts, used to set out in a fleet, and under convoy in time of war, and stop near the Isle of Rye, where they were joined by the ships from Rochelle, laden with wine, tallow, and corn; hence they proceeded to the coast of Brittany, where they were joined by another fleet from Nantes and St Maloes, laden with brandy, corn, &c. The fleet thus collected used frequently to amount to 160 or 200 sail. The very supplying of the city of Paris with wood for fuel, employs an immense number of boats, carts, &c. A large portion of the inland trade of France is still carried on by means of the numerous shipping.
FRANCE.

The French fisheries, as they existed previously to the Revolution, naturally divide themselves into two branches. The first branch comprehends the distant cod fishery on the banks of Newfoundland, Iceland, &c., and the whale fishery in the Greenland seas and the Southern Ocean; the second branch comprehends the near fisheries, on the coasts of France, in the Mediterranean, and in the ocean. These consist of the fisheries of the herring, the mackerel, the sardine, the anchovy, the tunny, &c.

Cod fishery. The French government does not appear to have paid any attention to the cod fishery on the banks of Newfoundland till the year 1660; and then a monopoly of it was granted. A few years after the peace of Utrecht, that is to say, about the end of the reign of Louis XIV. the whole produce of the cod fishery did not amount to more than a million of livres. When France lost Newfoundland, she established these fisheries at Cape Breton; and, in 1745, more than 100 vessels arrived there from the mother country to engage in them. There were, besides, at this period, from the Gut of Causo, down along the shore to Louisbourg, and thence to the N. E. part of Cape Breton, annually employed at least 500 shallops, containing in all 2500 men; and 60 brigs, &c. containing 900 men; in all, 3400 men. The total number of fish annually caught and salted at Cape Breton was estimated at 186,000 quintals.

There were also cod fisheries at other harbours on these coasts; so that, on the most moderate estimate, it was reckoned that there were 1,149,000 quintals of salted cod brought to France from all her North American fisheries; the value of which, and of the oil made, was estimated at upwards of £500,000 sterling. The war of 1756 was ruinous to this fishery; nor did the treaty of peace in 1783 quite re-establish it. In 1786 there were cured 426,400 quintals of fish, and upwards of 1000 tons of oil were made. In the following year, the quantity of both had greatly diminished, there being only 128,590 quintals of fish, and 323 tons of oil. In 1788 and 1789, the quantity of both increased; but, during the first years of the Revolution, both had fallen almost completely away. At the period of the Revolution, the produce of the French cod fishery was valued at 15,731,000 livres. In this sum is included the value of the sedentary fishery, as it is termed, of the inhabitants of the isles of St Pierre and Maquéline, which is rated at 1,500,000 livres; that of the inhabitants of Dunkirk, near Iceland, which is rated at 1,200,000 livres.

With respect to the whale fishery, it was carried on, in the beginning of the 16th century, by the inhabitants of Biscay, to a considerable extent, and with great skill, enterprise, and success; and, towards the middle of the 17th century, was very productive. The inhabitants of St Jean de Luz, Bayonne, and Ciboure, sent there between 50 and 60 ships, the Dutch not having yet embarked in it. In 1690, it wore a different aspect: the Basques scarcely sent out 20 vessels, while the Dutch sent out more than 300. At the end of the reign of Louis XIV. the Basques sent out from 12 to 15 vessels annually to this fishery. Since that period, this branch of fishery has been almost totally lost to the French; towards the middle of the last century, indeed, the government made some efforts to re-establish it at Bayonne and St Jean de Luz; but their efforts were unavailing. After the peace of 1763, the minister of the marine brought over to Dunkirk some Nantucket whalers, to assist and instruct the inhabitants in that fishery. At the commencement of the Revolution, there sailed from that port 15 vessels to Greenland and the South Seas; which is about the number that usually sailed towards the end of the reign of Louis XIV. The produce was valued at 700,000 livres. In 1794, 40 vessels were employed at Dunkirk in this fishery, but soon afterwards it was totally ruined by the war.

The herring fishery was pursued by the French in the 11th century, chiefly on the coasts of the Channel. At the end of the reign of Louis XIV. the produce of this fishery appears to have been about 1,200,000 livres; and at the commencement of the Revolution, 4,300,000 livres. The fishery of mackerel and sardines were established by the superintendent Fouquet, towards the end of the 17th century, principally at Belleisle, on the coast of Brittany. Like the herring, the sardine is a fish of passage, appearing upon the French coasts at certain seasons in shoals; but it is never found in any of the rivers. They are met with both in the ocean and the Mediterranean, especially in the latter. The small sardines caught on the coast of Provence, are esteemed by epicures as being superior to all others of this species. From 1000 to 1200 fish, swimming with and boats are engaged in catching these fish on the coasts of Brittany, Provence, &c. from the month of June to the middle of October. The French frequently cure their sardines in red wine, and when thus prepared, call them by the name of anchovettes, or anchovies. Fresh sardines are conveyed on board ships from the ports of France to the inland cities and towns of that country. Anchovies are fished for on the coast of Provence in the months of May, June, and July, at which season shoals of this fish come regularly into the Mediterranean. They are sent to Paris from Cannes, Antibes, St Tropez, and other places in Provence. Vast quantities of them are also exported to foreign countries. Pilchards are taken on the coasts of Brittany, and employ annually about 300 small vessels. The tunny fishery of the Mediterranean is a singular and important branch of industry: the manner in which this fish is caught, has been called a sort of hunting at sea; the best and most certain methods are the thonnaire and the madrague. The former in many places is only an inclosure formed by nets for catching the tunny; but at St Tropez, and on the coast of Provence, the thonnaire is a net placed in
a spiral form, in which the tunnies, when caught, are almost always dead, because it closes their gills, and chokes them, for which reason the madrague is preferred. This is, in fact, a vast inclosure, composed of three large nets, divided by others into many chambers or compartments; before the net, towards the open sea, is a large passage, formed by two parallel nets: the tunnies, running in between them, enter the madrague, and passing from chamber to chamber, they arrive at last at what is called the chamber of death, or the corpus, or corpus. After every thing has been made ready, the fishermen draw up the nets of each chamber, in order to force the fish to enter that, which must prove fatal to them. The fishermen are in the habit of throwing some drops of oil into the sea, and entirely covering their heads with cloths, to enable them to perceive whether any fish are in the inclosure. They also fasten at the bottom of their boat an ass's head, to entice the tunnies, which generally go to the edge of the corpus to see this head. The tunnies have great force in their tails, so that much caution is required in getting them into their boats. They come in such shoals, that in the height of the season, that is, in the months of May and June, from 500 to 600 are sometimes taken in a day, at one madrague only. They commonly weigh from 10 to 20 or 25 lb. each; but they have been known to weigh 50 lb. The tunny is eaten fresh in all places to which it can be conveyed sweet. The flesh, for so it may be called, is not less solid than that of the sturgeon. Pies are made of it, which are so celebrated, as to be sent all over France. When it is pickled, it is cut into slices, which are dipped in oil, after they are impregnated with the salt. The oil which comes from these fish when they are washed, and which is pressed out when they are seasoned, is used by tanners. The tunny fishery has been too productive since the war, for they are easily frightened; and the friction of the batteries of the coast appears to have kept them at a great distance. There are four madragues at Marseilles, which are rented out to the fishermen by the town, at a considerable advantage. There are also two at St Tropez, which are rented by the government at 10,600 francs. Two nets are necessary to each, and each net costs about 2000 francs. For the net of the corpus, 250 lbs. of cork are required. This net sometimes remains for a year or two in the sea; but those which form the internal chambers and the entrance passage, are changed every six months. The sea, in the spot in which the madrague is placed, is generally 40 fathoms deep. When Louis XIII. visited Marseilles in 1662, he was invited to a tunny fishery, at the principal madrague of Margion, and found the diversion so much to his taste, that he often said it was the pleasantest day he had spent in his whole progress through the south of France. Vernet, among his other sea-pieces, has a very good one of this fishery. The other fish caught on the Mediterranean coast of France, are the poulpe, which, though much smaller than the tunny, is probably of the same species; it is mentioned by Gibbon, in his description of Constantine, as, at the time of the foundation of that city, the most celebrated among the variety of excellent fish taken in the Propontes; the d'orade, the pageau, the loup, &c.

Coral.

Red coral is found in the Mediterranean, on the shores of Provence, from Cape de la Couronne to Cape St Tropez. They use two machines in fishing for it. The one, which pulls it from the rocks, is a large wood en cross, in the centre of which is a heavy leaden ball; at each extremity is fixed a round net. The divers push one or two arms of the cross into the cavities of such rocks as contain coral, and the boatmen draw it up. The other machine is used for drawing coral out of the deepest waters. It is a long beam, at the end of which is fixed an iron ring, having a reticular bag, with two round nets at each side. The ring breaks off the small branches, and the nets entangle and retain the others. A company has long been established at Marseilles for this fishery. There are seven or eight men to a boat, one of whom is the patron or proprietor. When the fishery is ended, which produces on an average 25 quintals of coral to each boat, it is divided into 18 parts, of which the proprietor has four, the caster two, and the other six men one each; the remaining one belongs to the company. Coral is part of the traffic of Marseilles. Bracelets and necklaces are made of it there and at Genis, and sell very well up the Levant.

Oysters are found in various places on the coast of Oysters France. At the mouth of the Seine, they are few in number, but of excellent quality. On the coast of Caen in Normandy, there is a bank six miles in length and one in breadth. They are also found in the bay of Isigny, and in the neighbourhood of Cherbourg. Those in particular are highly valued which are collected at the mouths of some streams, where the sea water is sometimes thrown entirely back, and which are called huîtres de pied. Granville in Normandy gains 50,000 livres by this fishery. On the coast of Brittany there are very large oysters, particularly at Courcelles, where a great many are preserved in places inclosed for that purpose. The oysters of Roscoff are also particularly celebrated; they are brought in great abundance to Morlaix, and are by some preferred to those of Courcelles. The bank at Painpol is almost entirely exhausted. At the mouth of the Loire, between the rocks on the coast of Poitou, on the coast of Annis and Saintonge, where those who make bay-salt transplant oysters to marshy places, also à la tète de Buch, near Bourdeaux, oysters are found. In Languedoc, near Cape Leucate, there is an oyster bed at the depth of 20 feet. There is also one at the mouth of the Rhone. At Paris, those oysters are most esteemed which come from Brittany, Rochelle, Bourdeaux, and particularly from Medoc, so celebrated for its claret. The principal fish which the rivers of France yield, are salmon, carp, trout, pike, and eels.

The importance and value of all these branches of home fishery are very considerable: At the end of the reign of Louis XIV. their value was at least 1,700,000 livres; at the commencement of the Revolution, it had increased to 9,300,000 livres.

Having thus given a detailed account of French industry, as exercised in agriculture, manufactures, commerce, &c. we shall conclude with laying before our readers an estimate of the value of the annual productions in these branches, or their gross produce at the close of the 17th century, and at the commencement of the Revolution; premising, however, that such an estimate must necessarily be only an approximation to the truth, and that it is interesting and important, not so much from its general result, as from the comparison which it presents between the value of different branches of industry.

In 1698, D'Avenant reckoned the general produce of the land, and of the interior and external commerce produce of France,—in short, the produce of all the occupations of her citizens,—at £81,000,000 sterling, or
The economist, some years previous to the Revolution, valued the annual reproduction at between 
8,154,000,000 and 4,000,000,000 livres.

In 1789 there appeared in France a memoir on the commerce of that kingdom and her colonies, which supplies the following details on this subject.

1. Agriculture.

**Total of manufactures, &c.** 584,950,000

| Produce of the agriculture of the colonies | 200,000,000 |
| Houses and other buildings             | 300,000,000 |
| Articles omitted                       | 149,050,000 |

**Total of agriculture, manufactures, colonial produce, &c.** 3,000,000,000

In this general result, M. Arnold, in his treatise *De la Balance du Commerce de la France,* M. le Trose *De l'Administration Provinciale,* 1788, and M. Dupont *Lettre a la Chambre du Commerce de Normandie,* nearly agree: the first gives the total at 3,400,000,000; M. le Trose calculates it at 3,154,000,000; and M. Dupont at between 3,200,000,000 and 4,000,000,000.

**CHAP. VII.**

There are scarcely any data, on which we can calculate the extent of the population of France, previously to the Revolution; yet it may be proper to notice some of the conjectures on this head. In 1577, the Duke of Nevers calculated that in the dominions of France, there were 3,000,000 of hearths; if we estimate each of them at six persons to a family, it will give a population of only 18,000,000. But at this period, neither French Flanders, Artois, Alsace, nor Lorraine, nor the counties of Burgundy, Roussillon, Ardeche, nor Bearn, were included in the monarchy. In 1581, the whole kingdom contained 96 bishoprics, and 133,000 parishes and hamlets. At the conclusion of the 17th century, it would appear from the reports of the intendants of the several provinces, that the population of France had not increased, since by them it is rated only at 26,093,000; and at this period great additions had been made to the territories of France. In the year 1754, the Marquis de Mirabeau rated the whole population still lower, viz. at 18,000,000. In 1772, the Abbé d'Expilly estimated it at 22,140,357; and nearly at the same period, Buffon estimated it at 21,672,777. In 1785, Necker rated it at 24,676,000. In 1789, M. Bouvallet Desbrouges estimated it at 27,057,267; and in 1791, the Committee of the National Assembly, from a more accurate calculation, stated it to be 26,563,074. In 1798, according to M. Prony, the population of France, including Corsica and the conquered countries, amounted to 31,123,218; viz. 26,014, 254 in the territories of ancient France; 3,511,055 in the Venaisin, Savoy, Nice, Geneva, the Austrian Netherlands, &c.; and 1,563,909 in the countries situated between the Rhine and the Moselle. In 1799, M. Dejeure, in his report to the Council of Five Hundred, stated it at 33,501,094. The senatus consultum of the 4th of August 1802, made the whole population of France amount to 33,111,902. This number, however, does not include Piedmont and the Isle of Elba. From these and other data, we may safely conclude, that the population of the kingdom of France, within the limits now prescribed to it, is nearly 26,000,000; or, if the destruction caused by the ambition of Bonaparte has reduced it below that amount, it will soon rise to it again.

Of the 26,563,074 inhabitants which, according to the report of the committee of the National Assembly, constituted the population of France in the year 1791, 5,709,270 were inhabitants of the cities, towns, &c. and 20,521,308 were inhabitants of the country. From this it appears, that at this period less than one-fourth of the people inhabited towns; and from Mr Birkbeck’s remarks, it is evident that this is the case at present, at least to an equal degree. His observations deserve to be quoted. ‘The population of France seems to be arranged thus: a town (Mouins for instance) depends for subsistence on the lands immediately surrounding it. The cultivators, individually, have not much to spare; because, as their husbandry is a sort of gardening, it requires a large country population, and has in proportion less superfluity of produce. Thus is formed a numerous but poor country population. The daily supply of the numberless petty articles of French diet, employs and therefore produces multitudes of little traders. It must be brought daily from the country; and the number of individuals whom this operation employs is beyond calculation. Multitudes, again, make a scanty living, by retailing through the streets these low-priced and perishable articles. The cultivator receives for his surplus produce in sous, and he expends only sous. The tradesman is on a par with the farmer; as they receive, so they spend. And thus
The following Table exhibits the population of different districts of France, as it existed at the end of the 17th century, and a few years previous to the Revolution; with the number of people to the square league, at each period, and the increase in the latter period. It may be proper to premise, that the population of the former period is taken from the report of the Intendants, and that of the latter period from the book of the administration of the finances of France.

Assuming the population in 1800 to have been 23,111,962, including all the territories at that time annexed, except Piedmont and the Isle of Elba, French and Austrian Flanders, which comprised the departments of the Scheldt, the Lys, and the North, contained 1,748,669 inhabitants within a territory of 4136 square miles, which is somewhat more than 422 inhabitants per square mile. The population of the country round Paris, notwithstanding the weight of that city in the scale, was inferior. If we take the two departments of the Seine, and the Seine and Oise, the department of the Marne, exclusive of the district of Fountainebleau, and besides the two districts of Beauvais and Senlis, which belong to the department of the Oise, we shall find in 1802 only a population of 1,496,223 over an extent of 4198 square miles. Next to Flanders, Normandy is the most populous district in France. The five departments of which it is composed, exhibit a population of 2,465,507 souls, in 1802, over a surface of 9175 square miles, equal to 2684 inhabitants per mile. The population of the southeast of France, on the contrary, is very small. In the three departments of the Alps there was not in 1802 more than 80 inhabitants per mile. The population of the Pyrenees was also very thin, though montane; that of the Pyrenees and that of the Arriege contained 900,167 inhabitants over an extent of 6552 square miles, or nearly 138 square mile. The most populous of all the departments, to the south of the 48 degree of latitude, is that of the Months of the Rhone, which, however, in 1802, contained only 320,072 inhabitants over a territory of 1550 square miles, or about 205 inhabitants per square mile. The population of most of the rest of the departments in this portion of France was very considerable; if, for instance, the eleven departments of Aude, Aveyron, Cher, Drome, Indre, Landes, Loire and Cher, Logere, Niévre, Var, and Vienne, be taken together, their population in 1802 will be found to be only 2,599,911 inhabitants over 25,778 square miles; that is, 109 inhabitants per square mile, which is little more than one-fourth of the population of Flanders. If the population of these eleven departments be added to that above stated of the Alps and the Pyrenees, it will appear that in 1802, there were only 2,017,320 inhabitants over a territory of 196,809 kilometers; whence it appears that this southern part of France contained then only the seventh part of its inhabitants, notwithstanding it is one-fifth of its extent. Thus it appears, that although one third part of France, as it existed in 1802, only lay on the north of the parallel of Paris, yet the population of the northern part, Paris included, was not much inferior to the southern division. Taking the whole population of France as it was in the beginning of 1802, when its territorial extent was 80,505 square leagues, it gives 1086 inhabitants for the square league. Estimating the acres at 191,729,295, and taking the population to be, as it was in the beginning of the Revolution, 26,363,074, there will at present be nearly five acres a head.

In 1802, Paris was calculated to contain 546,856 inhabitants; there were 3 cities, that contained above 100,000 each, viz. Bourdeaux, Marseilles, and Lyons; 8, from 100,000 to 50,000; but in these were included Antwerp, Brussels, Ghent, and Liege; 12, from 50,000 to 30,000; and in these also were included Cologne and Bruges; 22, from 30,000 to 20,000; 24, from 20,000 to 15,000; and 45, from 15,000 to 10,000. In short, at this period there were calculated to be 500 towns in the French republic as it then existed, containing 5,405,19 inhabitants. The annual number of births in France is as 1 to 25: and of these every 47th child in 1780 was illegitimate; the proportion of illegitimate children since the Revolution has very much increased, the calculation being that every 11th child is now illegitimate. The number of marriages is as 1 to 110. The number of deaths is as 1 to 30. The prefect of the department of the Doubs, on comparing the accounts of the children that died under 10 years of age in 1800, and of those that died under 10 years of age in 1802, found that 939 more children had died in that single department in 1800 than in 1802, and ascribed the difference to the great progress which vaccine inoculation had made in the latter period. In 1801, M. Morgues published a statistical Essay, containing the result of 21 years observations on the relative and actual number of births, deaths, and marriages at Montpellier, from 1771 to 1792. The average of the whole population, during the whole 21 years, was 32,897; during the three autumnal months there were one-fourth more births than during the three spring months; yet the greatest number of births was in January, and the least in June. The average annual births were 1197 or 1/7, one-half of
the whole population. The number of males born was to
that of females as 20 to 21. The illegitimate children
formed 4th of the whole annual reproduction, whereas
in Paris they formed 4th. The number of marriages
was 282, which to the whole population was as 1 to
118; of these that were born, 1 in 21 was married.
The number of deaths each year was 1412; and their
proportion to the whole population was as 1 to 293; of
these 546 were children under 10 years old. Win-
ter and spring were the healthiest seasons. The bur-
rials in August were to those in May, as 3 to 2. In
1777, 1779, and 1783, the small-pox was epidemic, and
in those years the annual mortality was increased by
429 children. In the 21 years above mentioned, three
men and 13 women died at the age of 100 and up-
wards; and one person in 74 arrived at the age of 70.
The condition of the great mass of the people in
France, with respect to their pecuniary circumstances,
since the Revolution, may be regarded as on the whole
improved; but at the same time, it indicates a state of
society by no means far advanced. The peasantry in
most places, as well as the small class of farmers, and
even the more extensive class of farmers in some parts
of the kingdom, grow, or make within themselves,
and all that their families consume, or wear; the
same comparatively little advanced state of society is
indicated by the not uncommon mode of paying for
labour by a part of what it produces or performs.
With respect to pecuniary wages, they are nominally
lower, not in fact higher than they are in England;
for though the money given is less, yet from the cheap-
ness of provisions, &c., it commands more of the
necessaries and comforts of life. In France, however, as
probably in all countries, at least in Europe, not only
the nominal but the real rate of wages has increased
gradually for a considerable length of time, and per-
haps in a greater proportion, within these last 30
years. In 1756, the price of labour at the places
mentioned below, was as follows: At Lisle, the wages
of journeymen stocking and camlet weavers, was
about 24 sous per day, that is about 13d. English:
The journey men weavers and cloth-workers at Abbe-
ville gained, according to the nature of their work,
and their dexterity, from 20 to 50 sous a day; where-
as women, at the same place, engaged in the
same manufacture, did not gain more than 12 sous a-
day. Hedgers and ditchers in the country only 10 sous
a day. At Nantes, the journeymen ship carpenters,
about 30 sous a day. At Castelmainard, labourers,
mending the canal of Languedoc, by the job, earned
about 12 sous a day. At Nismes, journeymen weavers
in the silk and cotton trade, from 30 to 32 sous a day.
At Marseilles journeymen tailors 30 sous a day.
At the same place, carpenters 30 sous; silk weavers from
30 to 35 sous. At Torlon, journeymen carpenters, in
the King's yards, 30 sous per day. At Lyons, jour-
ney men workmen had several prices, according to the silks,
velvet, gold stuffs, laces, &c. from 50 to 100 sous a day.
Land carriage of goods, from Marseilles to Lyons,
230 miles, from six to seven livres, per 108 lbs. Eng-
lish, (Tucker's Essay on Trade, p. 75.) When Mr
Young travelled in France, immediately before the Re-
ervation, he averaged the earnings on all the fabrics
manufactured in that kingdom, at 26 sous for the men,
and 15 sous for the women; the wages of the spinners
being nine sous. At the same time he calculated the
wages of the men employed in the manufactures of
England to average 20d. a day, or rather more than
20 sous; the women 9d. or rather more than 18 sous;
and the spinners 6d. or about 13 sous. On a compari-
on of these prices, it appears, that, at this period, the
wages of the men in England was nearly double the
wages of the men in France, whereas the wages of the
women in the former country was little more than what
it was in France. The average earnings of men through-
out the kingdom, employed in all sorts of work, Mr
Young estimated at 19 sous; masons and carpenters,
however, got 30 sous: He considered that the price of
labour had risen about 20 per cent. in the course of
25 years. The same author calculated the average rate
of wages for all kinds of labour in England, to be, about
1760, 1s. 3d. a-day; and in 1789, when he travelled in
France, about 1s. 4d. a-day. The result of his enqui-
ries respecting the comparative price of meat and bread
and the rate of wages in the two countries, in 1789,
was, that labour in England averaged 33 sous, while
meat was 85 sous, and bread 34 sous per pound; whereas
in France, labour averaged 19 sous, and meat was
7 sous, and bread 2 sous the pound. Hence it appears,
that the nominal price of labour was nearly 76 per
cent. cheaper in France than in England; and the real
price, considered with reference to its command over
meat, was less, while its real price, considered with re-
gard to its command over bread, was nearly the same
in both countries. In 1814, Mr Birkbeck seems to
have taken a good deal of pains to ascertain the com-
parative price of labour and provisions in France. He
found that, at Rouen, women who attended the looms
earned 15d. per day, equal to 11 pounds of bread; the
labourers employed by a small farmer in the neigh-
bourhood of that place, had 10d. per day, and their
board; and 20d. per day without board. On this he
remarks, that, "as all provisions, every article of ex-
penditure, may be taken at something under half the
English price, by doubling their wages, we may find
the proportion they bear to ours." In the south of
France, near Vienne, the French labourer received three
bushels and one-third for harvesting and thrashing, for
every 18 bushels threshed; the English labourer re-
ceives for the same work only about a tenth: money
wages are nearly in the same proportion. About Lannet,
the wages were 20d. per day for the men, and from
10d. to 15d. per day for the women employed in agricul-
ture; the former rate, considering the price of pro-
visions, Mr Birkbeck considers as equal to 3s. 4d. in
England.

Before the Revolution, the poor in France were uni-
versally supported, either by the ecclesiastics, or by
begging. Not long after the seizure of the ecclesi-
astical estates, the National Assembly publicly declared,
that they would consider the care of the poor as one of
their primary duties. They appointed also a commit-
tee of mendicati, whose business was to enquire into,
and report to the Assembly, the state of the poor, and
the best means of extinguishing indigence in France.
Of this committee the Duke of Lioncourt was the chair-
man. Four reports were laid before the Assembly;
in their third report, the committee examine the idea
of establishing a poor's rate, but with great wisdom ab-
solutely reject it. In their fourth report, however,
they declare that the poor have a right to pecuniary
assistance from the state; that the National Assembly
ought to consider such provision as one of its first and
most sacred duties; and that an expense, with this
view, ought to be incurred, to the amount of 50 mil-
ions of livres a-year. The unsettled state of France,
however, seems to have prevented the execution of any
plan founded on this report; and, at present, the poor

Statistics are supported in the following manner. In large towns there are generally two hospitals, one for the indigent sick; the other for the aged poor; these are supported by a small duty paid at the entrance of these houses, on all kinds of provisions, called l'Ocre d'Henfàissance; or rather, these octrois provide for the whole public expenditure, and part of the receipt is applied to the maintenance of the hospitals. A contribution, purely voluntary, is also made for the same purpose. In country communes, there is no regular provision; but, in cases of extraordinary distress, the mayor and council of every commune are authorised to apply relief.

Wood is the common fuel throughout France, and in some parts, especially in Paris, is a very expensive article. Coal, though, as we have already seen, it is by no means scarce, is seldom used, a prejudice existing against it: where turf or peat is found, it is used. The common people in general consume but little meat; bread made of rye, of rye and wheat, or of barley and wheat, chestnuts, maize prepared in different ways, and fruit, are their usual food: they drink but little wine, even where it is cheap and abundant. Their clothes being mostly made of materials grown by themselves, but they are generally supplied specially with linen, than the peasantry of England. To a person who has been accustomed to see nearly the same mode of dress in all parts of England, even the most remote, it seems singular to observe in France such a diversity of fashions: so little is the intercourse even between the capital and the adjacent provinces, that, in the latter, modes of dress are seen which have not prevailed in the former probably for nearly a century. The cottages of the peasantry are in general small; but in many parts of France by no means destitute of convenience or taste. In many of the vine provinces, the Vigneron inhabit cottages dug out of the sides of the chalk hills.

Before the Revolution, there were 18 archbishops and 112 bishops in France, besides six suffragan bishops. The number of parishes at that time was 40,000. There were 800 convents of monks, 261 nunneries, and 679 chapters. The number of religious of all kinds was estimated at 120,000, but there were nearly 200,000. There were also nearly 1,800,000 religious of both sexes. The whole number of clergy in 1799, was 3,543,750.

At present, the Roman Catholic religion is declared to be the only one allowed by the state; but the state provides equally for the ministers of the reformed church, either of the Lutheran or Calvinistic confession, and superintends even the synagogues of the Jews. The difference in religion is no bar to the advancement of any French citizen to the highest offices in the state.

By a decree of the National Assembly of the 12th July 1790, the archbishops were reduced to 10, and the bishoprics to 83; but, in conformity with the cordat concluded on the 25th July 1801, a new ecclesiastical arrangement was adopted which established 10 archbishops and 51 bishops in France proper.

As the constitution of France is yet unfixed, or, at least, is liable to alteration, we shall not pretend to give even a sketch of it; but as the arrangements for the internal government of the country will probably be per-

mitted to remain, they may be shortly mentioned: premising, that there are ten ministers and one secretary of state, viz. a minister for the department of the administration of justice, called the Great Judge; a minister for the foreign department—for the home department—for the financial administration of the kingdom—a chancellor of the exchequer—a war minister—for the administration of the war department—for the administration of naval and colonial affairs—for the general police of the kingdom—and for the religious institutions of the country. There is an inferior court of justice in every district, and a justice of the peace in every canton. There are a number of courts of appeal, and two supreme tribunals. Each department is administered by a prefect, and as many subprefects as it contains districts. The details of the administration descend from the subprefects to the mayors, who are not chosen by the people, but by the government.

The taxes paid before the Revolution may be classed under the five heads of direct taxes, monopolies, duties of excise, custom and transit duties, and stamps. The produce of the direct taxes amounted to about one-third of the whole revenue. One of these, the capitation tax, which fell very lightly on the nobility, and not at all on the clergy, yielded about one-fifth of this sum. The other direct taxes were the vingtiemes, which nearly resembled the English land-tax, and the taille, another species of land-tax, so unequally levied, that it fell almost exclusively on the poorer proprietors. The monopolies were that of salt, which, under the name of gabelle, was levied by government on about two-thirds of the kingdom; that of snuff, and that of brandy and other spirits, which was levied only in certain provinces. The excise comprehended taxes on leather, on the manufacture of starch, and of cards, on iron, oil, &c., besides other contributions. The transit duties included not only the customs payable on the export and import of merchandise at the sea ports, but also those which were levied at the gates of the towns, and a variety of tolls of different kinds. The stamp duties were levied on almost all kinds of contracts, and affected all changes of property. Under the old monarchy, according to Necker, the expenses of collection amounted to 10½ per cent. on all the taxes paid by the people. At this period, the farmers-general, the general and particular receivers, and all the subalterns in the service of the treasury, advanced sums to the government as securities for the faithful discharge of their trust. For these securities they were paid an interest of 5 per cent. and in some cases of 7.

The following were the taxes on land under the old government, according to Mr Young.

At the Revolution, the taxes of excise were completely abolished, and all the other indirect taxes materially simplified. The present regular revenue is derived from a land-tax, which is about 15 per cent. both for landlord and tenant; a personal tax; a tax on moveables and sumptuaries; on houses and windows; on patents; on the privilege of exercising any profession; additional centimes or hundreds; from the produce of the national domains and forests; customs, post-office, lottery, salt mines, &c. All these taxes in 1808, produced a total sum of 569,500,000 francs. The expenditure the same year amounted to 589,500,000 francs. The expenditure of collection was between 15 and 16 per cent. It was calculated by the minister of finance in this year, that the capital value of the real property of France was at least 50 milliards of francs.

Every village and commune of France has a collector or tax gatherer, who pays over the amount of his receipts to a treasurer, called a particular receiver, of whom there is one for every district. There is also a receiver-general for each department, into whose hands the particular receiver pays the sums drawn from the collectors, and who communicate directly with the treasury. They are all under the superintendence of an administration, entitled the Direction of the Taxes. In 1805, the number of chief officers belonging to the direction of taxes, amounted, throughout the empire, without including Piedmont, to 1,044.

It must be evident, that it is scarcely possible to gain an accurate idea of the revenue or expenditure of a country situated as France has been since the Revolution, and especially during the latter part of Bonaparte's reign; for, in the first place, the annual reports were evidently made up for the purposes of deceit; and, in the second place, had they been impartial, no conclusion of general importance could have been drawn from them, as so much of the wealth of France, or rather of the means of defraying her enormous expenditure, was drawn from plunder. Even the finance report of 1814, after the abdication of Bonaparte, must be received with caution; since the framers of it undoubtedly wished to exaggerate the evils his tyranny had caused, and, besides, hardly gave themselves sufficient leisure to gain an accurate knowledge of the real state of the finances. Premising these reasons for caution, we shall give some of the details of this report for 1814. The budget of the minister of the interior, states the mass of all the funds appropriated to the different services of that department, amounted, in 1811, to 145,000,000; in 1812, to 150,000,000; and in 1813, to 146,000,000. The public treasury never contributed to this mass of funds more than 60,000,000; the remainder arose from special duties and imposts. Till the accession of Louis, it was not known that the budgets of 1812-13 presented a deficit of 312,000,000. Till the commencement of the war in the Peninsula, all deficiencies were more than covered by foreign pillage: after that, while the expenses increased by the wars, the revenue fell off; so that, in a very few years, there was an addition to the national debt of 1,645,469,000 francs; the perpetual annuities alone, which he found it necessary to give, amounting to 47,000,000, equal to a capital of 300,000,000. One half of these, however, were employed in paying off former debts. The whole of the demandable debt, at the accession of Louis, amounted to 759,000,000 francs; at the time of the Revolution, it exceeded three milliards, or 3,000,000,000 of francs. The receipts of 1814 were calculated by the minister of finance at 520,000,000; the expenditure at 827,415,000, leaving a deficit of 307,415,000. The expenses of 1815 were calculated at 547,700,000; and the following were the ways and means proposed to meet these expenses. Direct contributions, 540,000,000; registry, domains, and woods, (the dominial forests still amounting to 1,400,000 hectares,) 120,000,000; posts, lottery, salt-works, tolls on navigation, and incidental receipts, 28,000,000; indirect contributions, 190,000,000; making a total of 618,000,000. We have given these calculations, though subsequent events rendered it impossible that they should be realized, because they exhibit a probable picture of what will be the resources and expenditure of France, when that kingdom is restored to tranquillity.

The amount of specie existing in France before the Revolution, was estimated by Neckar at 2,200,000,000 francs. In the year 1789, it is stated by Bouvallet Desbrosses, in his Table des Richesses de la France, at 2,474,254,960 livres, 350,000,000 of which consisted in notes of the Caisse d'Escompte. In the year 1807, Peulet, in his Statistique de la France, supposes it to have amounted, within the limits of the old territory, to 1,850,000,000. In 1789, it was calculated, that, in the maritime departments, the circulating medium amounted to 1,053,838,350 livres; and the business transacted by its means, to 4,485,600,000 livres. In those on the boundaries of France, the money in circulation amounted only to 385,227,000 livres, and the
statistics.

Bank of France.

business done with it to 4,283,600,000. In the central
departments, the circulating medium was 1,035,189,600
livres; and the trade carried on with it amounted to
11,874,600,000 livres.

The bank of France was established in 1801, or
rather it was new-modelled then, with a capital stock
of 30,000,000 of francs in specie, made up of 30,000
shares of 100 francs each. The amount of its notes
in circulation was generally about 4,000,000 sterling;
it dividend has always exceeded 5 per cent.; but only
that sum was paid, the surplus being reserved as a
stock when the dividend might be under 5 per cent.
Its notes are not a legal tender: it discounts the
acceptances of government and individuals; and
receives deposits of sums not below 50 francs, for which
it gives recognizances bearing interest. Its general as-
sembly is composed of 200 holders, each of five shares
or above, who elect fifteen directors and three censors,
each of whom must be holders of at least thirty shares.
Between 1783 and 1803, the bank of France was ex-
posed to four temporary suspensions, viz. in 1783, 1787,
1793, and 1795. In 1806, a much more serious stop-
age took place; and again, in 1814, when the allies
entered France, and just before Bonaparte left Paris, to
put himself at the head of his army.

The public funds of France consist of, 1st, Bank
shares, or actions de la banque, as they are called; and,
2d, Third consolidated, or tiers consoli-dés. The latter
is a 5 per cent. stock. The bank stock is disposed of
in shares, or actions of 1000 francs each.

On the 1st of May 1814, the land forces of France
amounted to more than 320,000 men, including all de-
scriptions. Besides this force, there were 125,957 mil-
itary of all ranks enjoying half pay: in Prussia, Rus-
sia, Austria, and England, there were 160,000 prisoners.
The pay of men in active service for the year
1814 amounted to 202,000,000 francs; the half pay to
34,000,000; making a total of 236,000,000 francs.
The war of 1812-13 destroyed, in artillery and ammi-
nition, 250,000,000; and the fortified places in the coun-
tries ceded by France, in the treaty of Paris, cost, since
the year 1806, 1,500,000,000 francs. Although we may now hope that the army of France,
that dreadful engine by means of which Bonaparte in-
flicted on Europe so many evils, is put beyond the power
of farther mischief, yet it may not be uninteresting to
notice its constitution during the period of its most
formidable strength. There were generally 90 infan-
try regiments, each at 3250 men each; 27 regiments
of light infantry, at the same number of men each; 2 re-
giments of carabiniers; 12 regiments of cuirassiers;
30 regiments of dragons; 24 regiments of chasseurs;
10 regiments of hussars; 8 regiments of artillery on
foot; 6 regiments of horse artillery; 22 battalions of
the artillery train; 16 companies of artillery labourers;
2 battalions of pontooneers; 9 companies of miners;
5 battalions of sappers; 1 battalion of gardes du genie.
These were commanded by 15 marshals of the empire,
150 generals of division, 500 generals of brigade, and
135 adjutants-commandants. The army was recruited
by voluntary enlistings, and by a rigorous conscrip-
tion, which comprised all Frenchmen from the age of 20
to 25, without any distinction of rank, fortune, or busi-
ness. Every soldier might rise to the highest rank;
no commission could be sold. The military spirit was
also animated by the decoration of a military order,
called the Legion of Honour, which is still retained.
It was originally composed of 16 cohorts, possessed each
of national domans to the amount of 200,000 francs
annually. Each cohort consisted of 7 great or superior
officers or dignitaries, 20 commandants, 50 officers, and
320 legionnaires. The great officers had an income
of 5000 francs; the commandants 2000; the officers
1000, and the legionaries 250. The knights of the
legion of honour amounted to between 6000 and
7000.

In the reign of Louis XIV. the French navy was
Naval strong enough to equip a fleet of 69 ships of the line, 7 frigates, 36 vessels armed en flotte, and 14 cutters, under
the orders of Toulouse, in the year 1690. In 1704, the
French fleet that fought the combined English and
Dutch fleets consisted of 50 ships of the line, 8 frigates,
and 9 fire-ships. In 1791, the French navy consisted of 73 ships of the line, 67 cutters, 19
sand 29 armed brigs, 7 gun-boats, besides several
hospital ships, galliots, &c. But the war with Eng-
land annihilated the navy of France. The efforts of
Bonaparte, however, were incessantly directed to its
re-establishment. According to the expose for 1814,
the most absurd of Bonaparte's schemes were those
which related to the establishment of a numerous and
territorial navy. Paris itself sawers had an emporium
within its walls. And what now remains of all these
armaments? The wrecks of some of the vessels and ac-
counts, which prove that for the successive creation and
destruction of this monstrous and useless flotilla,
uwards of 150,000,000 francs have been sacrificed since
1803. The grand works executed at Cherbourg, and
the fine squadron of Toulon, alone present useful re-
sults. All the arsenals are completely dilapidated; the
immense naval stores collected by Louis XVI. are squan-
dered; and during the last 15 years, France lost 43
ships of the line, 82 frigates, and 76 corvettes, which
could not be replaced at an expense of 200,000,000.
In 1814, the total debt of the navy amounted to 61,300,000
francs.

During the republican government, a system of uni-
form weights and measures was established upon a sim-
ple plan. The elementary measure is connected with
the dimensions of the terrestrial globe. This measure,
which is called metre, or mesure par excellence, is the
seven millionth part of a quarter of the terrestrial men-
dian, that is, of the distance of the equator from the
pole; it is equal to 3 feet 11.44 inches. The are
serves to measure the surface of the soil, in the same man-
ner as the arpent; it is equal to 100 square metres, or
948.44 square feet. The stere is equal to a cubic me-
tre, or $^{56}$,$^{12}$,$^{12}$ cubic feet. The litre is the measure
of capacity; it is equal to a cubic decimetre, or 30.425
cubic inches, or $^{12}$ part of the former pint of Paris. The
gramme marks the weight; it is equal to the weight of
a cubic centimetre of pure water, at its maximum
density. It has been found equal to 18.827 French
grains, of which 5.76 make 57.5 English; and 489.5058
grammes make a pound of the standard of the mint at
Paris.

These five primitive measures are successively mul-
tiplied or divided by 10, in order to form the greater
or smaller measures, by analogy to the decimal sys-
tem of arithmetic. The three divisors are deci, centi, and
milli, expressing the tenth, hundredth, or thousandth
part; thus decimetre is the 10th part of the metre, de-
ci metre the 10th part of the decimetre, and milli-
metre the 10th part of the centimetre, and the gramme
of a cubic millimetre. The multipliers are deca, heko, kilo,
and myria, denoting ten times, hundred times, thousand times, and ten thousand
times: thus the decimetre is 10 metres, the hectare
100 acres, the kilometre 1000 metres, the myriagramme
10,000 grammes.
Statistics.

The standard coin of France is a piece of silver of the weight of five grammes, or five times 18.4 grains, containing \( \frac{1}{4} \) th of alloy and \( \frac{3}{4} \) ths of pure silver, and very nearly the 34\(^{th} \) part of the pound sterling metallic value, being nearly the same with the livre tournois: it is called a franc, and divided into decares and centimes. There are pieces of 5 francs, 2 francs, \( \frac{3}{2} \) and \( \frac{1}{2} \) franc. The gold coins, like the silver coin, contain \( \frac{1}{4} \) th of alloy and \( \frac{3}{4} \) ths of pure metal. They are called Napoleons d'or or octo grammes: an octo gramme of gold is worth 25 francs.

Language.

The basis of the French language is Latin, on which are engrained Celtic and Gothic words and idioms. It is more remarkable for refinement and precision, than for energy or dignity. Their writers have rendered their language familiar to the lovers of literature throughout Europe; and in the value of their productions, they have no equals among the moderns, with the sole exception of the English. Even the mathematical sciences have been cultivated by them with a success, certainly not inferior to that of any other nation. Their taste in letters is purer than in the fine arts, in which there is a superabundance of ornament and an affected manner. Before the Revolution, there were 21 universities, and 89 academies and literary societies in France. During the Revolution a regular system of schools has been repeatedly decreed, though it does not appear that they have been actually established, or have at least proceeded so successfully and usefully, as the official reports represented. On the whole, however, education is more general now than it was previous to the Revolution.

The essence of the French character is an exuberance of animal spirits, producing excess of mobility, and a perpetual restless activity. They are quick, ingenious, fertile in expedients, buoyant against difficulty or adversity; but mutable, trifling, confident, vain, credulous, and incapable of moderation. With much that renders them amiable in society, as readiness to oblige, delicate attentions, kind sympathy, and lively sensibility, they are often of insecure commerce, from laxity of principle, unmeaning professions, jealous irritability, and a strong propensity to intrigue. Their feelings of every kind verge to excess; and there is nothing either good or bad, of which they are not capable, under the influence of their impetuous ardour. No cabinet has excited so much disturbance among the neighbouring states, from ambition and the spirit of intermeddling, as that of France; and we have seen, that no change of political system at home has made an alteration in their foreign policy. The French, beyond all people, are the creatures of society: by it their manners and sentiments are fashioned, and in it are centred their chief pleasures and gratifications. They would excel all nations in the art of conversation, were not the desire of shining too universal. The love of glory operates upon them with extraordinary force, and stimulates them to great exertions; but it is often attended with empty ostentation and gasconade.

FRANCHE COMTE. The name of one of the provinces into which France was divided before the Revolution. It now forms the departments of Doubs, Jura, and Saone. See France, p. 676.

FRANCIS. See France, p. 556—563.

FRANCONIA, a circle in the centre of Germany, and anciently a part of Thuringia, is situated between 14° 45' and 50° 50' North Latitude, and between 9° 20' and 12° 10' East Longitude from Greenwich. It extends in some places 140 miles from north to south, and between 90 and 115 from west to east. It contains 774,440 geographical miles, and 1,000,000 of inhabitants. It is distributed into different states or principalities, namely those of ecclesiastical princes, of secular princes, and of imperial cities.

I. The states of the ecclesiastical princes are the bishoprics of Aichstadt, of Wurzburg, of Bamberg, and the territories of the Grand Master of the Teutonic Order.

The bishopric of Aichstadt, or 'Eichted, is situated in the south-east corner of the circle, and is a tolerably fruitful country, watered by the Altmuhl, Anlauter, Schwarza, Sulz, and Retzat. Its principal towns are, Aichstadt (see Aichstadt), the episcopal residence, about 45 miles south of Nuremberg, remarkable chiefly for a curious piece of workmanship, in the church, called the sun of the holy sacrament, made of mosaie gold, and enriched with the most precious stones; Nassenfels, a borough and citadel, three leagues west of Ingolstadt, and in the south-east corner of the country where the ancient Aurenheim was situated; Abenberg, a small town and castle, where the counts of the same name formerly had their residence, and near which is at present a glass foundry for mirrors; Herreeden, Ohrenbue, Spalt, and several other small towns.

The bishopric of Wurzburg, situated towards the west part of the circle, extends about 90 miles from north to south, and 50 from west to east, and contains 262,000 inhabitants. It is watered by the Mayne, the Saal, the Tauber, and the Jax; abounds in grain, fruits, and pastures; and yields the best wine in Franconia. Its principal towns are, Wurzburg, a well-built and well-fortified city, containing a cathedral, an episcopal palace, an university, an observatory, several monasteries and churches, and about 16,000 inhabitants; Heydinsfeld, a little town on the Mayne, surrounded with vineyards; Veits-Hocheim, a small place about four leagues below the capital, containing a palace of the bishop; Kissingen, a little town on the Saal, having several salt springs and medicinal waters in its neighbourhood; Nunnerstadt, a small town on the river Lauer, containing a gymnasium, a cloister of the Augustine hermits, and a commandery of the Teutonic Order; Koenigshofen, a small fortified town on the Saal; Gerolshoven, an ancient town on the left of the Mayne, near to which are the ruins of the castle of Zabelstein; Volkach, a town on the Mayne, four leagues north-east of Wurzburg, which exports considerable quantities of wine; Thofen, Kilsingen, Ochsenfurt, all celebrated for good wine, and situated on the Mayne; Homburg, Dettelbach, and a great number of small market-towns.

The bishopric of Bamberg, situated east and south of Wurzburg, stretches upwards of 65 miles from southwest to north-east, is between 40 and 50 miles in breadth, and contains 195,000 inhabitants. It is divided into two equal parts by the river Rednitz, running from south to north, and falling at Bamberg into the Mayne, which waters the northern parts. The soil is generally fertile, producing abundance of grain, fruits, and wine; and near the capital there are so many trees of the laurel, fig, lemon, and orange, that it is sometimes called the little Italy of Germany. The principal towns are, Bamberg (see Bamberg), or Bohemian Bamberg, the capital of the district, a tolerably well built city, containing a magnificent cathedral, a large episcopal palace, an university, several monasteries, &c. and about 16,000 inhabitants; Forchheim, a fortified town, about 20 miles south of Bamberg, defended by a strong castle, and containing 4000 inhabitants; Schenslitz, a neat town with a castle, two leagues north-east of the capital; Cronach, a meanly built but fortified town, situated on an eminance, and containing 4000 inhabitants; Lichtenfels, a trading place on the Mayne, 20 miles north-east of Bamberg; Upper Scheinfeld, Vilsberg, &c.

The territories of the Teutonic Order, or Knights of the Virgin Mary, would form a considerable principality, if lying contiguous; but their estates are scattered throughout Germany, and consist of the masterdom of Mergenstein, and 12 bailiwicks. The bailiwicks of Franconia are divided into 15 commanderies, named from the places where the property of the order is situated, Ellingen, Wiernsberg, Nuremberg, Wurzburg, &c.

II. The states of the secular princes are chiefly those of Bayreuth, or Kulmbach; Ansbach, or Onolfsbacht; Limburg, Schwarzenberg, Wertheim, Erbach, Henneberg, Hohenlohe, and several others of trifling extent.

The principality of Bayreuth or Kulmbach, belonging to the house of Brandenburg, borders on Bohemia, and extends upwards of 30 miles eastward, and 25 from north to south. It is generally fertile and well cultivated, diversified with mountains and plains, but in some tracts remarkably hilly, rugged, and barren. The elevated ridge of Fichtelberg, or Mons Pomiferus, nearly 16 miles in length, and one of the highest mountains in Germany, contains mines of iron; copper, lead, antimony, &c. crystals and marbles of various colours, and gives rise to a number of rivers, especially the Mayne, Saal, Eger, and Nabi. The whole principality contains about 205,000 inhabitants. Its principal towns are, Bareith or Bayreuth (see Bareith), the capital, and the residence of the Margrave, a considerable town, containing a palace, castle, academy, &c. and about 10,000 inhabitants; St George, a town situated on the small lake Weyher, and containing an elegant palace recently built; Kulmbach, formerly the Marigave's residence, a small town, pleasantly situated, slightly fortified, and containing 2800 inhabitants; Himmelkron, a large village, with a palace of the prince, in a pleasant valley on the White Mayne; Hof, an ancient town on the Saal, containing 4700 people; Wunsiedel, a neat trading town on the Fichtelberg, containing 2400 inhabitants; Weisenstadt, a small town near the source of the Eger, in a wild and barren tract, formerly much famed for its mines of tin and copper; Creuzen, a small place, remarkable for its fine earthen ware; Erlangen, (see Erlangen,) near the influx of the Schwabach into the Rednitz, eleven leagues south-west of Bayreuth, consists of two small towns, the most recent of which was built by the French refugees after the revocation of the edict of Nantes, and contains several handsome streets, an elegant palace of the Margrave, an university, manufactures of hats, stock-
The principality of Ansbach, or Oeselbach, is bounded by the territories of Bayreuth, Bamberg, and Wurtzburg. It is generally fertile; but some parts are remarkably mountainous and sandy. It is watered by the Jaxt, the Rednitz, and the Altmühl; and near the village of Graben, some remains may still be traced of the canal between the two last of these rivers, by which Charlemagne opened a communication, in 793, between the Danube and the Rhine. The principality contains 215,000 inhabitants; and its chief towns are, Ansbach, or Anspach, (see Ansbach,) the residence of the Margrave, a well-built town containing 13,000 people, and situated in the centre of the country; Schwabach, a manufacturing town, situated on the river of the same name, about 18 miles east of the capital, containing 6000 inhabitants, and noted for its hardware, stockings, and tapestry; Wendelstein, a handsome town, seven miles east of the last mentioned place; Cadolzburg, a considerable town surrounded with walls, and defended by a castle; Furth, a well-built and trading borough, about five miles north of Nurnberg; Roth, a little manufacturing town seven leagues south-east of Ansbach, famed for its weavers of stocking and lace, and for an imperial asylum for persons guilty of manslaughter; Uffenheim, a handsome and flourishing manufacturing town, with several good public buildings, about 25 miles north west of Ansbach; Heilsbrun, Feuchtwang, &c.

The principality, or rather lordship of Limburg, lying south-west of Nurnberg, extends about 20 miles from north to south, and 18 from east to west. It contains 15,000 inhabitants; and its principal towns are, Upper Sonthem, Gaidorf, Markt-Einersheim, defended by a castle, and Sommerhausen, fortified with a rampart and ditch.

The county of Schwarzenberg, north-west of Nurnberg, and in the interior of the circle, is about 20 miles long and 5 broad. It contains 24,000 inhabitants; and its principal towns are, Markt-Schainfeld, Geiselwind, Markt-Brat, &c.

The county of Wertheim is situated between the territories of Mentz and the bishopric of Wurtzburg, and is traversed by the river Mayne. It yields a considerable produce of wine; and its chief places are, Wertheim, Remlingen, Freudenberg, Hochst, Helbach, and Brabant, formerly celebrated for its aqueducts, which were destroyed by Turenne in 1675.

The county of Erbach, nearly surrounded by the territories of the Lower Rhine, is about 20 miles in length and 16 in breadth; mountainous, but well cultivated, provided with quarries of stone and marble, and several good mines of iron. Its chief towns are, Erbach, an old town with a citadel and wall; Michelstadt, which has an iron foundry in its vicinity; Freienstein, Forstena, &c.

The county of Henneberg, in the northern part of the circle, is about 40 miles from east to west, and from 20 to 30 from north to south, and is traversed by the river Werra. There are several forests and mountains, mines of iron, salt, and mineral springs in the country. Grain and tobacco are raised in the more level districts. It is divided into several portions belonging to the electoral houses of Saxony, Saxe-Weimar, Saxe-Gotha, Hesse-Cassel, &c. Its principal places are, Schleusingen, near the forest of Thuringia, containing 2000 people; Sulfa, a manufacturing town three leagues farther north, containing 6000 inhabitants; Ilmenau, on the eastern border, with several mines of copper and silver; Meiningen, in the centre, seven leagues west from the last mentioned, containing 3500 people; Salzungen, near the north border, celebrated for its salt springs; Schmalkalden, a considerable manufacturing town, three leagues northward from Meiningen, and famed in history for the league of the Protestant princes in 1531.

The principality of Hohenlohe, of a very irregular figure, is about 40 miles from east to west, and 25 from north to south. It is watered in the western part by the Kocher, and in the eastern by the Tauber and Wurtitz. Its mountains afford various kinds of timber; its valleys are covered with excellent pastures; and its southern hills are clothed with vineyards. It contains 80,000 inhabitants. Its principal towns are, Ochringen, in the south-west corner, containing 3900 people; Frankenau, a considerable manufacturing place near the source of the Wurtitz; Kunselsau, situated in a hilly quarter, and containing 2100 inhabitants; Ingelingen, Kirchberg, &c.

Besides these, are the counties of Reineck and Castell, and the lordships of Hausen, Welsheim, Seinsheim, Reichelsberg, and Wesentheil, which are of very little extent, each containing only a small town, or a few villages.

The imperial cities are Rotenburg, an old and well-built town in the county of Ansbach, containing 8000 inhabitants, surrounded by walls and strong towers; Windsheim, a small fortified place in the same county, containing 2500 people; Scheinffurt, a small fortified town on the Mayne; Weissenburg, a small place in the bishopric of Aichstadt; and Nurnberg, or Nuremberg, which will form the subject of a separate article. The more remarkable also of the towns here mentioned, will be found under their respective titles.

The districts of Bamberg and Wurtzburg, contain some of the best land in Germany, and abound in all the necessaries of life. The inhabitants are skilful in agriculture; but in manufactures, are very far behind their more northern neighbours. In the vicinity of Bamberg, the art of gardening is practised to a great extent; and immense quantities of small pickled girkins, the best onions in Germany, and especially liquorice roots, are carried as far as Holland as articles of trade. The common people believe that there is no liquorice in any other part of the world, and that the possession of this root was given to them as an exclusive privilege by St. Cunigunda, who is interred in their cathedral. Notwithstanding, however, of the excellence of the soil, and the gentleness of their ecclesiastical rulers, the people in these two rich bishoprics are in general extremely poor; and more beggars are to be seen among them than in many of the less favoured districts. This has been ascribed partly to the dissipated and luxurious manners of the inhabitants, and to the numerous acts and institutions of charity, which the Roman Catholic system (the prevailing religion of the country) is supposed to produce.

In the territories of Bayreuth and Ansbach, the bounties of nature are less liberally bestowed; but a greater spirit of industry prevails among the people; and the inhabitants, though loaded with taxes, are in much better circumstances than in the fertile districts of the southern states. In the smaller principalities, the people in general are subject to great oppression, especially those whose masters reside in the greater courts. They are not only thus deprived of the advantages which would arise from
the rents and revenues being expended on the spot, but are also subjected to the tyranny and exactions of despotic deputies. See Playfair's Geography, vol. iv. and Reisbeck's Travels through Germany, vol. iii. (q)

FRANKEKER, a town of Holland in West Friesland, situated in the district of Westero, and in the canton of Franekeradeel. It stands about two leagues from the Zuider Sea, near the canal which stretches between Leuwarden and Harlingen. Franeker is the second town, and one of the nearest in Friesland, being adorned with very fine buildings, both public and private. It is celebrated for its university, which possesses a fine library, and which was established in 1585 by the states, and by William Louis, Count of Nassau. It possesses also a castle, which was erected in the 15th century, and served as the residence of the governors of Friesland. Between Franeker and Harlingen, there are many tile-kilns, where varnished tiles of a deep colour are fabricated. About a league from the town is Kleins-Lankum, the residence of the celebrated Camper, and where one of his sons continues to increase the splendid collection of minerals and petrifications begun by his father.

The mean temperature of this town, according to five years observations, was 52° 6'. The maximum heat was 82°, and the greatest usual cold 12°. East Longitude 5° 28'; and North Latitude 53° 11'. (q)

FRANKFORT, on the Mayne, an imperial city in the circle of the Upper Rhine, is about 36 miles eastward of Menz, and is situated in the centre of the finest district of Germany. It was anciently the residence of the Frankish monarchs, and is still the place where the electors of the empire hold their meeting for choosing an emperor. The city is large, and contains about 60,000 inhabitants, including the Jews. It is divided into two unequal parts by the river Mayne, over which there is a bridge composed of 14 arches. The town is well fortified, and is surrounded with a broad ditch very full of water. The ramparts are planted with limes, and afford agreeable walks to the inhabitants. Most of the houses are built of timber, lath, and plaster, and constructed in the antique form, having the upper stories projecting over the lower; but they are kept in good repair, and have always a fresh appearance. The principal houses are built of red or white stone, and many of them are splendid edifices. The principal streets are wide, and there are three spacious squares, which add greatly to the beauty of the place, and in which are situated the houses of the opulent merchants, and the palaces of the neighbouring princes. Considerable additions have lately been made to it, comprising a square and 18 streets, which are filled with inhabitants. The public buildings most worthy of notice, are the cathedral church of Bartholomew, and the Römer, or Stadhuis. The cathedral belongs to the Catholics, and is a large ancient Gothic structure, said to have been erected by Pepin of France, and enriched by Charlemagne; but it was completely plundered by Louis of Bavaria; and has neither statues, paintings, nor ornaments. The Römer, or town-house, is an immense Gothic pile, bearing the marks of great antiquity, and containing various chambers for the transactions of public business. In the chamber of the electors, are several good paintings; and the grand hall contains a regular series of portraits of all the German emperors, from the time of Conrad in the year 900. Among the archives, is deposited the famous golden bull of Charles IV, which contains the fundamental laws of the Germanic constitu-

tion, written on parchment, in High Dutch, says Bishop Burnet, (who confesses, however, that he did not see it,) but, according to Cogan, in the Latin language. The Lutheran church of St. Katharine, is also a magnificent building, ornamented, says the prelate just quoted, with as much painting as any Popish church, and having a huge carved crucifix over the high altar. The pulpit is extremely fine, constructed of marble of different colours, nicely polished and joined. The city is not encumbered with suburbs; but is surrounded with the country seats and pleasure gardens of the richer inhabitants, intermingled with public houses and tea gardens, for the entertainment of the ordinary citizens. No town in Germany, or perhaps in Europe, is more celebrated for excellent inns; but there exists a very oppressive law, by which the innkeepers, except at the time of the fairs, can prevent strangers from occupying private lodging, and compel them both to eat and to sleep in the taverns. Frankfort is one of the principal commercial towns in Germany; and many of its merchants are possessed of considerable wealth. Riesbeck reckons that there are 200 houses or companies, who have annual incomes of 100,000 guilders, or £10,000 sterling and upwards; and in furniture, equipage, and dress, there is a great appearance of luxury among the higher rank of citizens. The trade, however, is of a description unfavourable to the country; and Frankfort has been termed "the great canal by which the gold of the empire runs out." There are considerable manufactures of silk, cotton, linen, woollen, carpeting, porcelain, tobacco, iron ware, &c.; but the principal traders are little better than brokers, commissioning articles of internal consumption. The export of German commodities from this channel, scarcely amounts to one-tenth of the imports from other countries, which consist of all kinds of spices, female ornaments, handkerchiefs, silks, and the various articles of luxury, furnished by Italy, France, and Holland. As the way to the principal high roads of Germany lies through the direction of Frankfort, there is always a conourse of fashionable company in the town; and several thousands of strangers are attracted to its great fairs, where the southern parts of Germany are supplied with various commodities. Of these fairs, there are two in the year, one in the spring, and another in the autumn season. Its situation on the Mayne, and its proximity to the Rhine, renders it the magazine of all the merchandise which is conveyed by these rivers, to the different parts of Germany. Besides the number of traders (about 1600) and private purchasers, by whom these fairs are frequented, multitudes are attracted by the love of gaiety and amusement; and the city becomes, during their continuance, as much a scene of licentiousness as a mart of business. The municipal government of Frankfort is of a very mixed and intricate description; and warm contests are continually carrying on between the aristocratical and popular interests. The spirit of litigiousness is described as unusually prevalent in the place; and the annual expense of the law suits, in which the magistrates are uniformly engaged with the burghers of the city, or with the neighbouring princes, is estimated at 50,000 rix-dollars. The annual revenue is about 600,000 guilders, or L. 30,000 sterling, which is raised chiefly from the customs and excise; but partly from the contributions of the burghers. There are two rates of contribution, one of 50 and the other of 25 guilders per annum. The former is imposed upon those who have an annual income of 30,000 guilders and upwards; and
FRANKFORT. the latter upon smaller incomes; but every person esti-
mates his own property, and consequently taxes himself, which it sometimes becomes the interest of the merchants to fix at the higher, rather than the lower rate. The ci-
tizens who are not Lutherans, have greater taxes to pay, while they possess fewer privileges. The Calvinists are wholly excluded from the rights of burgesses; and the Catholics, though admitted to that distinction, are not allowed to take any share in the government. The inhab-
habitants of this city have a peculiar institution, called col-
leges, or associations of persons of the same rank or pro-
fession, colleges of nobles, colleges of lawyers, colleges of physicians, colleges of booksellers, colleges of all orders and artists; so that a stranger, upon being introduced into any of these, finds himself instantly acquainted with the most re-
spectable persons of his own station. Many of the wealthier inhabitannts possess considerable private collec-
tions of paintings, and of natural curiosities. These they take great pleasure in exhibiting to strangers; but are apt to exhaust both the patience and politeness of the vis-
itors, by their tedious description of the minutest arti-
cles. Many of the principal literary characters of Ger-
many, and well-informed men in every branch of the arts and sciences, may be found in Frankfort; but the low state of religious toleration, indicates a tardy pro-
gress in the path of real civilization, and in the spirit of 
true Christianity. While in manners and conversation there is too great a degree of licence; there are, in the exercise of public rights, many partial and preposterous restrictions. The established religion is the Lutheran; but both the Catholics and Calvinists are nearly equal to them in number, and the latter rather superior in point of wealth. The Catholics enjoy their principles and ob-
servations in full liberty, and have numerous chapels, mo-
 nasteries, and nunneries; and the Calvinists, who about 20 years ago were obliged to resort to Saxenhauen, a village on the opposite side of the Main, in order to 
observe public worship in peace and tranquillity, have now two handsome places of worship within the city, one German, the other French. There are 10,000 Jews in 
Frankfort, who have a considerable synagogue, and en-
joy a precarious toleration. They are found too useful to be totally eradicated, but are often subjected to such oppressions, as the self-interest of their persecutors will permit. The streets, to which their residence is re-
stricted, were formerly inclosed with walls in such a man-
er, that, if thought necessary, they could be imprisoned in a body by locking the gates; and their habitations were so crowded, that in seven of the houses, which scarcely occupied a space of fifty yards, and which happe-
ned to be burned down, there were found to have dwelt twelve hundred individuals. There is a law, which pro-
hibits them from residing in any other part of the city, and even from appearing out of their own enclosure; but it is only occasionally enforced, and sometimes in order to extort money for the exemption. At other times they are forced out of their retreat, to perform the more ser-
vice offices, such as to carry water in cases of fire, &c. They are a most industrious people, and some of them possess considerable wealth. They are chiefly employ-
ed in selling toys, and dealing in old clothes, of which they receive vast quantities from England; but they re-
fuse no kind of occupation, however degrading or dis-
honourable. "Those who go into their streets," says 
Riesbeck, "are in danger of being pressed to death by 
them. They fall upon strangers by dozens, and compel 
them to buy their wares. It is very difficult for a man to disentangle himself from them without the help of a good stick; and they call to strangers from the distance of three or four hundred paces." Since their quarter of 
the city, however, was nearly consumed by fire, they have been dispersed over all the town, which they great-
ly prefer to their old habitations. East Long, accord-
ing to solar observations, 8° 36', and North Lat. 50° 7' 29'. See Küttners Travels through Denmark, and 
through Germany, vol. iii. Cogan's Journey on the Rhine, 
vol. ii. Bishop Burnet's Travels; and Letters on a 
Tour through Germany. (q)

FRANKFORT, on the Oder, a city of Germany, in 
the circle of Upper Saxon, and middle mark of Brand-
denburg, is a well built and trading town about 15 leagues 
south-east of Berlin. It contains a cathedral, a bishop's 
palace, two colleges, and several churches. The churches 
are large and well built, and the bridge over the Oder is 
about 280 feet in length. A simple monument has been 
erected to the memory of the poet Kleist, by the lodge 
of free masons in this city, in 1778; and the place where 
Prince Leopold of Brunswick perished, in generously 
attempting to save a fellow-creature from the waves of 
the Oder, is distinguished by a beautiful monument of white 
marble. In one of the churches, the same humane act 
is commemorated by a painting from the pencil of Rode. 
There is also an academy, a society for promoting the 
arts and sciences, and a Calvinistic university, which was 
established in 1506 by the Elector Joachim and his bro-
ther Albert. There are three annual fairs in this city, 
and it draws considerable advantages from the naviga-
tion of the Oder, and the canal of Muhlrose, by which 
it has an indirect communication with the Baltic. The 
number of inhabitants is 10,000. East Long, accord-
ing to sidereal observations, 14° 33' 15'; and North 
Lat. 52° 22' 8". (q)

FRANKING OF LETTERS. See Post-Office.

FRANKINCENSE. See Guns.

FRANKLIN, BENJAMIN, the celebrated American 
politician and philosopher, was born at Northampton, 
in the year 1706. He was the youngest son of Josiah Franklin, a silk dyer in Northamptonshire, who 
removed to America in 1682, where he embraced the 
occupation of a soap-boiler and tallow-chandler, reared 
a numerous family by honest industry, and was distin-
guished among his townsmen as a person of sound judg-
ment, and sober piety. His other sons were put ap-
prentices to different trades; but Benjamin was destined 
for the church; and, at the age of eight years, was sent 
to a grammar school. He was removed, however, at the 
end of the first year, to a school for writing and arith-
metic; and at ten years of age, was taken home to as-
sist in his father's occupation. From his earliest years 
he discovered a passionate love of reading, especially the 
 accounts of voyages; and he mentions Plutarch's Lives, 
and De Foe's Essay on Projects, as among the few books 
of general information to which he had access. This 
 inclination for books, and the strong aversion which he 
shewed to the occupation of his father, suggested the 
plan of binding him apprentice to one of his brothers, 
who had established a printing-house at Boston. In this 
situation, he had an opportunity of procuring better 
books, and pursued his studies with such avidity, that he 
frequently spent the whole night in reading. He soon 
began to commit his own thoughts to writing; and by
making summaries of papers from the Spectator, which he afterwards endeavoured to expand, from recollection, into their original form, he laboured to improve his style without any other instructor. When about 16 months of age, he adopted, from some work which fell into his hands, the fancy of adhering exclusively to a vegetable diet; and proposed to his brother, that, if he would allow him per week one half of what was paid for his board, he would undertake to maintain himself. Out of this little fund, he contrived to purchase books, as well as to pay for his subsistence; and, by his new mode of living, saved much time for his favourite pursuits. When my brother and his workmen left the printing-house to go to dinner, I remained behind; and dispatching my frugal meal, which frequently consisted of a biscuit only, or a slice of bread and a bunch of raisins, or a bun from the pastry-cook’s, with a glass of water, I had the rest of the time, till their return, for study; and my progress therein was proportioned to that clearness of ideas and quickness of conception, which are the fruit of temperance in eating and drinking. By perusing the works of Shaftesbury and Collins, he became a sceptic in religion, and began to adopt the Socratic method of reasoning, especially on that topic, as at once the safest to himself, and the most embarrassing to his opponents, obtaining often in this manner victories, which, by his own confession, “neither his cause nor his arguments merited.” Having sent to the newspaper, printed by his brother, several anonymous pieces, which were very favourably received by the critics of the place, he became a little more sensible of his own attainments, and could less easily brook the severe treatment which he frequently experienced as an apprentice. His brother, being of a passionate temper, and his own impertinence sometimes serving as a sufficient provocation, he was often punished with blows. Having, besides, given offence, by the freedom of some of his pieces in the newspapers, both to the friends of government and of religion, he determined to quit at once the service of his brother, and the place of his nativity; but, despairing of being able to gain his father’s consent, he secretly sailed to New York at the age of 17 years, without the aid or approbation of his friends, and with no more money than what the sale of a few of his books could enable him to raise. Being disappointed in his hopes of employment in that city, he proceeded to Philadelphia, where he arrived after a fatiguing journey, weary and hungry, without an acquaintance in the place, and with no greater stock of money than a Dutch dollar in his pocket. He soon found employment as a journeyman printer; and his literary attainments having attracted the notice of the governor, Sir William Keith, he was encouraged, by the flattering promises of his patron, to conceive the design of commencing business on his own account; and at last, after a short delay, he accepted the offer of the governor to advance the necessary sum for his establishment in business, and sailed for London to purchase the materials of his intended printing-office. Upon his arrival in London, he found himself the dupe of false professions; and discovered that his friend Sir William Keith was either unable, or had never intended to furnish him with those letters of credit and recommendation upon which he relied. He therefore employed himself as a journeyman printer in London, that he might improve his knowledge of the profession; and never failed to recommend himself to those whom he served, by his assiduous application to business. After spending about 18 months in this manner, and increasing considerably his stock of knowledge by means of the acquaintance which he made with several literary characters, and the opportunities of reading which he enjoyed, he engaged himself as clerk to Mr. Denuit, a merchant of Philadelphia, and returned with him to that city in October 1726. But, in the beginning of the following year, he was deprived of this excellent friend by death, and was once more obliged to resume his occupation of printer, under his first employer in Philadelphia. In a short time, however, he opened a printing office in partnership with one of his fellow printers; and, by indefatigable industry, soon acquired a sufficiency of funds and of friends to undertake the whole of the business. About this time, he mentions, in his Memoirs, that he had for several years been completely unsettled in his belief of religious principles, and even of moral obligations; but having witnessed in many of his companions, the demoralising influence of such opinions, he became practically convinced of the importance at least of truth and probity in the transactions of human life; and, though uninfluenced by any respect for revelation, he was preserved by the good effects, it may be supposed, of his pious education, from gross immorality or injustice, and confirmed in a serious resolution to pursue a course of undeviating uprightness. He soon acquired the reputation of a most industrious and punctual tradesman, and his friends and employers daily increased. He instructed, in 1728, a literary society named the Junto, which subsisted during the space of 40 years, and became the foundation of the American Philosophical Society. At the same time, he published a new periodical paper, to which he drew the attention of the public by his own ability in writing; and particularly brought himself into notice, by a pamphlet on the Nature and Necessity of a Paper Currency.

In 1730 he entered into the married state, and continued to prosper in business, to improve in knowledge, and to advance in public usefulness. He was chosen, first, printer, then clerk, and at length member of Assembly, in which he represented the city of Philadelphia for 14 years successively. He was indefatigable in suggesting various useful improvements and institutions for the benefit of the community; and particularly contributed to the formation of a “Library Company” in 1731; the establishment of an insurance office against damages by fire, in 1738; the enrolment of volunteers for the defence of the country in 1744; the foundation of an academy and charitable school in 1749, which afterwards was erected into a college or seminary of general learning; and the endowment of the Pennsylvania Hospital in 1750. He accomplished a beneficial reform in the police of the city; ministered to the daily comfort of his fellow citizens, by his improved plans of chimneys and fire places; and essentially promoted the interests of frugality and industry among the lower orders, by the publication of Poor Richard’s Almanack. In the midst of these humble labours, he gave abundant evidence of his penetrating philosophical genius, by prosecuting a course of interesting experiments and discoveries on the subject of electricity, which, about the middle of the last century, had engaged so much of the attention of scientific enquirers: (See Electricity.) But, from the time that he became a member of the Assembly of Pennsylvania, in 1747, his attention was so much directed to public affairs, that the greater part of the remainder of his life...
was devoted to political pursuits. Keen contentions were then carrying on between the Assembly and the proprietaries of the provinces; and he soon became a leading character in opposition to the latter. He seldom spoke in the course of the debate which took place; and when he did rise to address the house, his speeches often consisted only of a single sentence or a well-told story, and were always expressed in the most concise and simple style. But his judgment was unusually penetrating; and he has frequently been known by a single observation, delivered in his plain manner, to decide the fate of an important question.

In 1754, when a meeting of commissioners from the northern provinces was held at Albany, in order to concert measures of mutual defence against the French settlements and Indian tribes, Franklin attended as delegate from Pennsylvania, and produced a plan which has generally been called the "Albany plan of Union." Though unanimously approved by the commissioners, it was finally rejected both by the provincial Assemblies and the king's council, upon principles which seem to establish its excellence as a just medium between political extremes. By the ministry of Great Britain, it was considered as giving too much power to the representatives of the people; while it was rejected by every assembly as giving to the president-general, the representative of the crown, a disproportionate and dangerous influence.

In the alarm which followed the defeat of Braddock in 1755, Franklin introduced a bill into the Assembly for organizing a kind of voluntary militia, and for some time acted as colonel of a regiment raised in Philadelphia; and, in 1757, he was chosen agent for the province of Pennsylvania to present a petition on the part of the Assembly to his Britannic Majesty, against the measures of the proprietaries.

After much discussion before the Privy Council, the prayer of the petition was partially granted upon condition that Franklin would solemnly engage, that the assessment should be so levied as to bear equitably upon the estates of the proprietaries; a proposal which testified at least the high opinion entertained of his honour and integrity. He still remained at the court of Great Britain as agent for the province of Pennsylvania; and, in consequence of the knowledge and fidelity with which he conducted the interests of the colonies, he was soon appointed to the same office for the provinces of Massachusetts, Maryland, and Georgia. He was now in a situation where his merits were sure of being duly appreciated, and where his claim to literary honours was fully acknowledged.

He was admitted a member of the Royal Society of London, and of similar institutions in other parts of Europe; and the degree of Doctor of Laws was conferred upon him by the universities of St Andrews, Edinburgh, and Oxford. He was soon engaged in a correspondence with the most eminent philosophers of Europe, and never desisted entirely from philosophical studies. It was during his residence in London that he directed his attention to the electrical properties of the tourmalin, the effects of cold produced by evaporation, the causes of the north-east storms in North America, and the construction of the musical glass instrument the *harmonica*. But his time was chiefly occupied with political objects; and a pamphlet which he published, on the importance of Canada to Great Britain, is supposed to have suggested the expedition under Wolfe for the conquest of that province.

After his return to America, in 1762, the disputes between the proprietaries and the Assembly were again revived, and increased to such a degree, that, in 1764, a resolution was adopted by the latter, which Dr Franklin supported with all his ability, to petition the King for an alteration of the proprietor into a regal government. In the election which took place in the end of that year, the party of the proprietaries having gained a small majority in the city of Philadelphia, Dr Franklin lost his seat in the Assembly; but his friends in that house still holding the superiority, he was again appointed provincial agent at London. After his return thither, he was examined at the bar of the House of Commons on the expediency of the stamp act; and, on that occasion, gave a striking proof of the accuracy of his information, and the facility of his expression. In 1766, he made a visit to Holland and Germany, and, in the year following, to France, experiencing every where the most friendly reception from men of literature and science. In the progress of the disputes between Great Britain and the American colonies, he exerted himself to the utmost, both in his conversation and correspondence, to effect a change of measures, and to point out the evils which a perseverance in those that were adopted must ultimately produce. Finding all his endeavours to restore harmony entirely ineffectual, he returned to America, in the year 1775, immediately after the commencement of hostilities, and continued to bear a leading part in the memorable struggle, which terminated in the political independence of the colonies. He acted as envoy of the States, in all their most important negotiations with Britain, with France, and other European powers; and, after his return to Philadelphia, in 1785, was elected president of the supreme executive council of that city. About three years afterwards, he withdrew from all concern in political affairs; but, under all the infirmities of age, aggravated by a painful disease, he was ready to co-operate in every measure of public or private good. He was president of the Philadelphia Society for alleviating the miseries of public prisoners, and also of the Pennsylvania Society for promoting the abolition of slavery. One of his last public acts, was the signing of a memorial from the last mentioned association, to the House of Representatives; and the last production of his pen was an ironical defence of the slave trade, in the form of a speech, supposed to have been delivered in the Divan of Algiers; an inimitable parody of the arguments of the anti-abolitionists, and a striking evidence of the strength of intellect which he possessed to the last. During the concluding twelve months of his life, he was confined almost entirely to bed, by a calculous complaint, which had afflicted him for several years; but died at last of an imposthume in his lungs, in April 1790, in the 83d year of his age.

The life of Dr Franklin affords a striking proof of the influence in society of a sound understanding, united with steady industry, and supported by candid integrity; and presents a useful lesson to all young persons of unsteady principles and showy accomplishments. His writings and discoveries also, on so many subjects of practical utility, produced, without any advantages of regular education, or literary society, forcibly illustrate how far a vigorous and well-directed mind may carry its possessor, without the minutiae of learning, and the theories of science. He has distinguished himself in various departments of knowledge, in natural philosophy, in political economy, in general literature, and in practical morality. His physical speculations were almost uniformly suggested by views of utility, and are distinguished by the unparalleled facility with which he conducts his reader from one step of the en-
FRASERBURG, a town of Scotland, in the county of Aberdeen, is situated on the south side of the point called Kinnaird's Head. The streets, which are spacious, intersect each other at right angles; and the houses, which are neatly built, are covered with slates and tiles. The prison and town house stand near the centre of the town. The cross is a fine hexagonal structure, with three equidistant hexagonal abutments. The ground area is about 500 feet, and a stone pillar, 12 feet in height, surmounts the whole. In the west end of the town stands an old quadrangular tower, of three stories, which is part of a large edifice, intended for a college, which Sir Alexander Fraser was empowered to erect by a charter from the crown in 1509. The harbour of Fraserburgh, though small, is nevertheless good, having from 11 to 16 feet of water, and admitting vessels of 300 tons. There is good anchorage in a bay contiguous to the harbour, of about three miles long, and one broad. Linen yarn is manufactured here to the extent of three or four thousand pounds annually. A light-house has lately been erected by government on the top of the old castle, situated on the promontory of Kinnaird's Head.

* The latest and most complete edition of the Works of Dr Franklin is that which was published in London, in 3 vols 8vo. 1806.
The following is an abstract of the population of the town and parish in 1811:

See Statistical Account of Scotland; and Stark's Gazetteer of Scotland. *(w)*

**FRAUENFELD** is the name of a small town of Switzerland, and the capital of the canton of Thurgovia. It is situated upon the banks of the Mourg, a river which rises in the mountains of Allmann, and in a country where there are only a number of low hills. The annual assembly of the Confederates was formerly held in this town. There are here manufactures of figured stuffs; and about the end of the 18th century, there was discovered near the town a mine of pitchcoal. *(w)*

**FREDERICK III.** King of Prussia, generally distinguished by the appellation "Great," was the eldest son of Frederick William II. of Prussia, and of Sophia Dorothea, daughter of George I. of Great Britain. He was born at Berlin on the 24th of January 1712, and was baptized by the name of Charles Frederick, but afterwards entirely omitted the former of these names, both in his private letters and public state papers. He was committed, in his infancy, to the care of Mad. de Rocco, who spoke only in French; and this circumstance has been considered as the origin of his extreme partiality to that language. At seven years of age, he was provided with more appropriate tutors; but, as his father's great object was to inspire him with a military spirit, he seems to have received little instruction in literature or science. He applied himself, however, in early youth, to the study of the belles lettres, particularly to poetry; and soon discovered a strong propensity to music, to which the king his father had an extreme aversion. He was strictly prohibited either to practise or to hear it, and was obliged to meet his musical instructors in a forest or a cavern. Harassed by the austerity and violence of his father,—dissatisfied by the difficulties thrown in the way of his favourite studies,—and perhaps moved by some other reasons which have never been distinctly ascertained,—he adopted a resolution, in the year 1730, secretly to quit the Prussian dominions, and to travel as a private individual in France or England. His intentions having been discovered, he was arrested, together with his travelling companions; one of whom, Lieutenant Catt, a youth of amiable dispositions, was condemned to lose his head on a scaffold; and the young prince was compelled, by his brutal father, to witness the untimely end of his friend. By the same paternal care, he was himself imprisoned in a dungeon for the space of six months; and, had not the Emperor of Germany interposed in his behalf, would also have suffered death. He was then permitted to enjoy greater liberty, but was still required to reside at Custrin, till, about 18 months after his arrestment, a formal reconciliation took place between him and his father. But, as if only partially restored to favour, he seldom appeared at court, and resided chiefly at the retired castle of Rheinsberg—a circumstance which enabled him to prosecute his studies with greater assiduity, and which probably contributed in no small degree to his future greatness. In 1733, he was compelled, by his father's despotic command, to marry the princess of Brunswick Wolfenbatttle, niece to the Empress of Germany; but was so utterly averse to the match, that, though he submitted to the ceremony, and received the lady into his palace, he refused to cohabit with her as long as he lived. He was attended in his retirement by many literary characters, particularly by M. de Suhn, privy-counselor to the Elector of Saxony; and in 1736 he commenced a correspondence with Voltaire, to whose writings he became peculiarly attached. In 1738 he accompanied his father on a tour to Holland, for the purpose of visiting the Prince of Orange; and in consequence of a conversation which took place at the table of their host, Frederick resolved to join the fraternity of free masons. He was then in the 27th year of his age, and is described by one of his biographers, who was present at the ceremony of his initiation, as possessing at that age a very youthful appearance, large blue eyes, pleasing features, a sprightly look, and noble air, and the greatest politeness of manner. He continued, with a number of sprightly and literary favourites, to spend his time at Rheinsberg in a succession of refined and studious pleasures; and the most flattering pictures have been drawn by those who shared his pursuits, of the intelligence of his mind, and the attractions of his society. "All the employments," says Baron Bielfeld, "and all the pleasures of the Prince, are those of a man of understanding. His conversation at table is charming. He talks much, and excellently well. His mind seems to be equal to all sorts of subjects; and his imagination produces, on each of them, a number of new and just ideas. His genius resembles the fire of the vestals, that was never extinct. A decent and polite contradiction is not disagreeable to him. He possesses the rare talent of displaying the wit of others, and of giving them opportunities to shine on those subjects in which they excel. He jeasts frequently, and sometimes rallying, but never with asperity, and an ingenuous retort does not disable him. He was much employed in exercising the troops under his command, in attendance at reviews, and in occasional journeys with the king; but generally resumed his literary pursuits with renewed ardour, upon returning to his retreat at Rheinsberg, and often spoke of his residence there, as the happiest period of his life. The greatest interruption of his tranquillity arose from the want of money, which his parsimonious father was always reluctant to grant; and he was obliged to borrow considerable sums from the Empress of Russia, and Duke of Courland. On the 1st day of June 1740, he succeeded his father, as king of Prussia, and his accession to the throne was welcomed by the unanimous acclamations of his subjects. Immediately after the funeral of the deceased monarch, he applied himself to public business with the utmost assiduity; and, among other regulations, instituted a new order of knighthood, called "the order of merit," with the professed design of rewarding meritorious individuals, without distinction of birth, religion, or country. Soon after his accession, he invited many learned and scientific characters to his capital; and adopted measures for establishing an academy of sciences in that city. He next proceeded to visit different parts of his dominions, in order to receive the homage of his subjects; and set out incognito to Strasburgh, that he

---

*This Prince is frequently designated Frederick II. his father being in that case marked as a William, and not a Frederick.*
might take a view of the French frontiers. He intended to have proceeded to Paris, under his famed name of the Count du Pom, but, having been recognised on his way, he turned aside to Cleves, where he had his first interview with Voltaire, whom he employed to publish his refutation of Machiavel, at the very moment when he was exemplifying the principles which he condemned, by levying a contribution on the city of Liege, and enforcing a questionable claim to the surrounding district. From the very commencement of his reign, he seems to have formed a plan for the increase of his territories; and, by the death of the Emperor of Germany, an extensive field was opened for the operations of his ambition. Disregarding the Pragmatic Sanction, by which all the powers of Europe had guaranteed the Emperor's hereditary dominions to his eldest daughter the Archduchess Maria Theresa, he revived some obsolete claims to the duchy of Silesia, and took immediate possession, with an army of 30,000. He made himself master of Glogau by surprise, defeated the Austrian army at Molwitz, reduced the cities of Briesg and Neiss, entered Breslaw, the capital, without opposition, and having publicly received the homage of the Silesians, returned in triumph to Berlin, about the end of the year 1741. Early in the following year, he again joined his army; gained the hard contested battle of Czaslau over the Austrian General, Prince Charles of Lorraine; seized the favourable moment for securing the territory which he had conquered, by negotiating a separate peace with the Queen of Hungary; and resumed, amidst the acclamations of his citizens at Berlin, the internal administration of his kingdom. With a small retinue, and with his usual rapidity, he went through a great part of his dominions, inquiring into grievances, inspecting his revenues, and ascertaining the condition of his troops. But, in the midst of apparent peace, and while externally occupied in the institution of a new academy in his capital, and the celebration of his sister's marriage with the Prince Royal of Sweden, he was making the most active military preparations; and, under pretence of preserving the Germanic constitution from the encroachments of the House of Austria, he issued the most artful mandates, and at the head of 60,000 men suddenly entered the kingdom of Bohemia. He took the city of Prague, and was pursued his conquests with more than ordinary vigour; but, by the able and rapid exertions of Prince Charles of Lorraine, a stop was put to his progress, and he was compelled, with immense loss, to make a precipitate retreat into Silesia. He was so extremely mortified by the disastrous result of this campaign, that he is said to have forbidden all conversation on the subject at his court; and hastening to retrieve his lost honours with an army of 70,000, he came upon the Austrians unexpectedly at Hohen Freiberg, where he gained a complete victory, as much by his own crafty generalship, as by the valour of his soldiers. Marching forwards into Bohemia, he was suddenly met and attacked in his camp at Sohr, by his enterprising adversary the Prince of Lorraine; but though thus taken at great disadvantage, and assailed by superior numbers, he took his measures with so much promptitude and skill, and received such able support from his officers and men, that, besides repulsing the attack with spirit, he routed the enemy with great slaughter. Sending his army into winter quarters, he entered Berlin in a triumphant style, with the cannon and colours which he had taken from the Austrians; but, hearing that the Prince of Lorraine still continued his movements, he returned rapidly to the field; and, after a series of successes, entered the city of Dresden, where he concluded a treaty of peace in 1745, securing the possession of Silesia, and receiving a million of German crowns from the Elector of Saxony. Returning to his capital with all the pomp of victory, he displayed the utmost affability towards his applauding people; and, while making the circuit of the city in the midst of the illuminations, he halted in his progress to take a last farewell of one of his early preceptors, who was lying at the point of death.

In the year 1746, a season of general peace among the powers of Germany, Frederick was wholly occupied with matters of domestic policy; and adopted various regulations for the prosperity of commerce, literature and the arts. He directed his attention particularly to effect a thorough reform in the courts of justice, especially to lessen the delays and expenses of legal proceedings; and at length produced the famous Frederician Code, which was adopted in all the Prussian dominions. In concurrence with the President Maupertuis, he framed, about the same time, several additional rules for the Royal Academy; but he treated his philosophers rather like a regiment of soldiers, and attempted too much to regulate matters of taste and opinion by kingly authority. During the same period of peace, he published his "Memoirs of the House of Brandenburg," and his "Poem on the Art of War," the former, a work written with spirit, and full of valuable information, though not always free from mistakes and misrepresentations; and the latter, a performance neither destitute of poetical merit, nor deficient in sound principles of military science, but remarkable for the extraordinary omission of the name of Marlborough, while the generals whom the British commander frequently defeated are furnished with their respective portions of fame. He employed himself much in embellishing some of his principal cities, and among other measures, which he adopted for the benefit of his subjects, he asserted their right to navigate the seas without interruption from belligerent powers, so that he has been considered as the author of the system of maritime neutrality. He exerted himself by every method to increase the population of his dominions; and, in this view, expended large sums of money in clearing waste lands and forming navigable canals; gave great encouragement to French Protestants and other industrious emigrants to settle in his territories; and particularly succeeded by these means in populating and fertilizing the deserts of Pomerania.

In 1749, he was visited by the celebrated Mareschal Saxe, whom he treated with every mark of distinction; and in the year following, after various applications, he prevailed upon Voltaire to reside at his court, whom he created one of his chamberlains, and provided with an annual pension of 20,000 livres. But their friendship was not of long duration; and they were both too ambitious of despotic power in the republic of letters to exist harmoniously in the same circle. The king was disgusted by the familiarity with which the French wit behaved to him in public, and with the sarcastic remarks in which he sometimes indulged even upon his royal person. His majesty also was much offended.

* This work was first published in the German language, and afterwards in French. An English translation was printed at Edinburgh, in 1761, in two volumes 8vo.
by a money transaction of rather a dishonourable description, in which Voltaire had engaged with the aid of a Jew; and the other wits at the Prussian court, envious of his high favour, took care to report to the monarch's ear the most offensive of his sayings. But the principal cause of their greatest misunderstanding and final separation, was the decided part which Voltaire took against Frederick in a dispute between Maupertuis and Koenig. Even this open dissension was in some measure composed, when his majesty sent a message to Voltaire, requesting him to write an apology to Maupertuis, the Frenchman burst into a violent rage, and desired the messenger to tell the king that "he might go to hell." Still, it is said, they had another interview, in which they were seemingly reconciled, and Voltaire received permission to go to Plombieres for the benefit of his health; but the king having afterwards discovered, that Voltaire had written a satirical piece against him, he sent a letter dismissing him from his service, and requiring him to return the contract of their engagement, with a volume of poetry, with which he had been entrusted. Voltaire immediately left Berlin, but retained possession of the contract, which bound Frederick to pay him 20,000 livres a year, and of the poetry, which he considered as a present; but he was arrested at Frankfort on the Maine at the king's instance, and treated in a most unworthy manner, till he made the required restitution.

In 1753, Frederick exerted all his influence to prevent the election of a king of the Romans, which was considered as a measure highly conducive to the peace of Germany; but which, as tending to aggravize the house of Austria, he was anxious to obstruct; and, by his persevering opposition, prevented its execution for many years. In 1756, he concluded a treaty with his Britannic Majesty, in which they mutually stipulated for the defence of their common country, to prevent all foreign troops from entering on any pretence into Germany. But the great army which Frederick maintained, his indefatigable diligence in exercising his troops, and his well known enterprising spirit of ambition, having long excited a general apprehension among the neighbouring powers, an extensive confederacy, or partition treaty, was at length concluded, between Russia, Austria, Poland, the Elector of Saxon, and the court of Versailles, to restrain his projects and retrench his power. Dissatisfied with the explanations which he had demanded of Austria, respecting her military preparations, and which the Empress had assured him were entirely defensive, he resolved to commence hostilities without delay, and precipitately involved himself in a long and hazardous war, in the course of which he acquired, indeed, a high degree of military fame, but reduced his kingdom to the eve of destruction. In 1756, he published his declaration of war against the Empress of Germany; entered the Electorate of Saxon with an immense army; seized upon its revenues, magazines and archives, and proceeded to administer its offices of government, by persons of his own appointment, as if it had already been incorporated with his own dominions. By his active and skilful manoeuvres, he forced the Saxon army to surrender, after defeating the Austrians under Marechal Brown, who had advanced to its relief; but he tarnished the glory of his victory, by cruelly compelling the Saxon troops to enter into his service, and to fight against their own sovereign. His ambitious and unjustifiable measures called forth the strongest declarations from the principal governments of Europe; and, as Elector of Brandenburg, he was, by a decree of the Aulic council, put under the ban of the empire. He opened the campaign of 1757, with an army of 200,000 men; and, though the Russian, French, and Austrian forces, united against him, amounted to more than three times that number, he poured his soldiers into Bohemia, before the Austrians were aware of his approach; and, joining his columns with extraordinary rapidity, unexpectedly and completely defeated the enemy at Prague. By a strict blockade of destructive, he reduced the city to the utmost extremities; and, by the joint effect of his calculating cruelty and military skill, was on the point of compelling 50,000 Austrians, within its walls, to surrender, when his good fortune sustained a fatal reverse, and his own impetuous confidence subjected him to a defeat. Attempting with an inferior force to dislodge Marechal Daun, who had advanced to Collin for the relief of Prague, he was routed with dreadful slaughter, and obliged to retreat with all his troops towards Saxony. His favourite brother, William Augustus, a prince of great abilities, and singularly amiable character, devotedly attached to his person, who had repeatedly distinguished himself in his service, having suffered some loss in bringing off the division with which he was entrusted, and having ventured to remonstrate with Frederick upon the calamities of the war, was dismissed with the most humiliating reproaches, and driven, by the harshness of his treatment, to a state of the deepest melancholy, which terminated his life in the course of the following year.

The difficulties of the Prussian Monarch now began to multiply with fearful accumulation. The loss of some of his ablest generals, the junction of the Swedes with his enemies, the capture of Memel by the Russians, the successes of the French against the Electorate of Hanover, the progress of the Austrians in Silesia, and their entrance into Berlin, where they levied a contribution on the inhabitants, reduced his affairs to a situation of the most critical nature, and drove him at one time to form a design of committing suicide. He communicated his intention to his most intimate confidant the Marquis D'Argens, in what he called his farewell letter; but received from his friend an immediate reply, so expressive of affection, and convincing by its reasons, that he was roused from despair, and animated to further efforts. Collecting his troops, he attacked the French at Rosbach; and, with very little loss on his side, gained a splendid victory over an army, which was double the number of his own. Hastening by forced marches into Silesia, where his troops were hard pressed by the Austrians, he gave battle to the enemy at Leuthen, and, by a disposition of his line, coinciding with that which was made by Eparimondes at Leuctra, gained a most signal victory, which put 40,000 prisoners into his hands, and gave him complete possession of Silesia. The resolute resistance which he maintained against his numerous enemies, the rapidity with which he recovered his losses, the greatness of his enterprise, the splendour of his victories, the military skill, mental fortitude, and personal courage, which he had displayed in the whole of this memorable and eventful campaign, attracted the attention of surrounding nations, and gained him the applause even of his opponents. Aided by a large subsidy from Great Britain, where the fame of his exploits had acquired him extraordinary popularity, he opened the campaign of 1758 with the happiest prospects. Entering Moravia, he attempted, without success, to reduce the city of Olmutz; and hastening to the Oder, where the Russians were committing the greatest ravages, he routed them with
great slaughter at Zorndorf. Having returned to the
Elbe, he sustained a severe repulse from Marshal
daun at Hochkirchen in Lusatia, where he lost
marshal Keith, and was himself slightly wounded, but af-
terwards succeeded in forcing the enemy to retire from
Saxony; and in one campaign twice made the circuit of
his dominions, relieving them all in their turns from
their formidable invaders.

In 1759, his operations were so extremely unsuccess-
ful, that, had his enemies known as well how to im-
prove as to obtain victories, he must have been utterly
undone. After watching, for some time, the motions of
Marshal Daun, he hastened in person to oppose the
Russians on the Oder, and engaged them at Kunes-
dorf, at first with great advantage; but having, contra-
ry to the advice of all his generals, attempted to crush
their reserve with his exhausted troops, he suffered of
his severest of his defeats, after having two horses killed
under him, and his clothes penetrated in several places
with musket balls. Never, however, did the resources
of his genius, and the fortitude of his spirit, appear
more remarkably, than after this adverse stroke; and,
aided by the dissensions which prevailed between the
Russians and Austrians, he covered his capital, and kept
his powerful opponents by bay during the winter. Af-
ter several unsuccessful overtures respecting peace, in
which he shewed no inclination to cede an inch of his
territories, and in which he was no farther sincere,
except in hoping to detach one or more from the confe-
deracy, he renewed the unequal contest with his usual
spirit and perseverance. In 1760, he had occasion for
all his ingenuity, and was obliged to employ his tactics
more than his firelocks. Nearly surrounded by three
armies, each superior in number to his own, he baffled
all their plans of attack, by incessantly changing his po-
positions; and succeeded at length in extricating himself
from his difficulties, by surprising and defeating Lau-
dohn at Paßendorf, while Daun was expecting to over-
whelm him at Lignitz. He removed the Russians out
of his way, by causing a letter with false intelligence
to fall into the hands of their commander; and thus
opened his communications with Breslaw; but was un-
able to prevent a body of Austrians and Russians from
occupying Berlin, and pillaging his palaces. Still
threatened by hostile masses in every quarter, and per-
ceiving his only safety to lie in preventing their junc-
tion, he determined to commit his cause to the fate of
a battle; and, after a desperate and sanguinary conflict
with Daun at Torgau, he gained a victory which re-
moved the most formidable and most immediate of his
dangers. Unable, however, though sufficiently lavish
of blood, to bear the loss which every victories required,
he resolved, in the campaign of 1761, to act solely on
the defensive; but, at the same time, by often threaten-
ing an attack, to conceal the purpose which he had
adopted. He therefore entrenched his army in a camp
of singular strength near Bunzelwitz, in Silesia, on
which he set at defiance the numerous divisions of the
enemy, by which he was threatened on every side.
Obliged by want of provisions to change his fortified
posts, he often contrived, by distributing ammunition
and preparing his arms, to impress his opponents with
the persuasion, that he designed some daring assault;
and on one occasion he actually kept a superior force
of Russians and Austrians in such a state of alarm, that
they slept eight nights on their arms, in the expecta-
tion every moment of being roused by his approach. In
1762, though the assistance of Great Britain was with-
drawn, yet, having engaged the Tatars to make an
irruption into Hungary, and acquired a zealous ally by
the accession of Peter III. to the Russian empire, he
was enabled to gain ground upon his enemies, and to
threaten them with invasion in their turn. Though
speedily deprived of his Russian auxiliaries by a new
revolution at St Petersburg, he availed himself so ex-
peditiously of their presence, that he entirely recovered
Silesia and Saxony, ravaged the frontiers of Bohemia,
sent detachments to Bamberg and Nuremberg, and
spread terror to the very gates of Ratisbon. Favoured
by a variety of circumstances, which disposed the
courts of Vienna and Versailles to open proposals of
peace, he readily entered into negotiations for a gen-
eral pacification, which was concluded at Hubertusburg
on February 15, 1763; and thus, after a seven years
sanguinary struggle, to which his unprincipled projects
had given rise, and in which independent of other suf-
ferers, more than half a million of combatants had fal-
len in the field, every thing was replaced on its ancient
footing, and the only gainful result was simply this,
that Frederick of Prussia had been furnished with an
opportunity of proving himself a consummate com-
mander, animated by an unconquerable spirit of mil-
tary heroism, and ended with one of the coolest heads
and hardest hearts in Christendom.

Returning to his capital, after an absence of nearly
six years, Frederick applied himself, with all his ta-
lents and perseverance, to the internal improvement of
his kingdom; rebuilt the towns and villages, and remu-
erated the individuals who had suffered during the
war; and afforded every encouragement to agriculture,
manufactures, and commerce. But he always regarded
the army as the principle object of his attention; and
in a very short time after the peace of Hubertusburg,
his regular force amounted to 200,000 men. Little
scrupulous in the means by which he accomplished his
schemes, he defrayed much of his expenditure by is-
suing base money, which he compelled his subjects to
take in payment; but which he ordered his commis-
sioners to refuse in collecting the taxes. For the
purpose of populating his own territories, he carried from
the neighbouring provinces of Poland many thousand fa-
milies; and, in order to round his dominions, he was
the prime mover and most active perpetrator of the in-
famous partition of that country in the year 1777. He
was not disposed, however, to tolerate similar acts of
robbery, in which he had no share; and, when the Emperor
Joseph took possession of Bavaria, he resisted his un-
just pretensions, and conducted in person the cam-
paign, which was terminated by the peace of Teschen. The two last
of his public acts were the establishment, in 1785, of the
Germanic union for preserving the constitution of the
empire; and a treaty of amity and commerce, in 1786,
with the United States of America.

Frederick was now seventy-four years of age, in full
possession of all his mental powers, but extremely debi-
litated in his corporeal frame. He began to suffer much
from dropsy, without being sensible, (or at least with-
out being willing to allow,) that he was afflicted with
that disorder. He nevertheless continued his attention
to public business, without the smallest interruption.
Rising at four o'clock every morning, he employed him-
self several hours with his three principal secretaries,
reading dispatches, dictating answers, and directing the
most minute transactions of his government. The go-

dernor of Potsdam then a third o'clock to receive his orders respecting the daily duty of the gar-

dison. He next admitted a physician for a few minutes-
to give direction respecting his health. He then conversed with his friends until mid-day, when he generally dined alone. In the afternoon he signed the dispatches and letters, which he had dictated in the morning. He joined his friends again in conversation from five to eight o'clock in the evening; and, after their departure, listened to passages from ancient authors till he retired to rest. In this course of labour he persevered till two days before his death; although for several weeks preceding, he was so swollen with the dropsy, that he could not move without assistance, and was obliged to remain day and night in his chair. Though he suffered dreadfully, he betrayed no symptoms of easiness or impatience; but conversed with great composure on general subjects, and without ever alluding to his own state of health. On the 16th of August he was deprived of sense, while his friends were reading to him from Cicero and Plutarch; and on the morning of the 17th, he expired without any convulsive motion, in the 75th year of his age, and the 47th of his reign.

Frederick, in his person, was below the middle stature, and of a slight form, but possessed of a vigorous constitution. In his earlier years his figure was graceful; but in the latter part of his life, in consequence of incessant fatigue, or as some suppose of his incessant custom of making extremely low bows, he stooped considerably, and his head was inclined to one side. He was short-sighted, and his eyes were of a fine blue colour, but full of fire, and expressive of uncommon keenness and penetration. His tone of voice was extremely clear and agreeable; and he spoke with the utmost fluency and sprightliness. He was, especially in the latter part of his life, a great economist, or rather uncommonly shabby in his dress, which was usually a plain suit of regimentals, consisting of a blue coat faced with red, and yellow waistcoat and breeches. He always wore boots, which being rarely renewed, were generally of a dirty brown colour. His hair was simply queued, and he had no other mark of distinction than the order of the black eagle. His whole wardrobe, says Dr Moore, to whom it was shewn at Potsdam, consisted of two blue coats faced with red, the lining of one of a little torn; two yellow waistcoats a good deal soiled with Spanish snuff; three pair of yellow breeches, and a suit of blue velvet, embroidered with silver for grand occasions. I imagined at first, that the man had got a few of the king’s old clothes, and kept them here to amuse strangers; but upon enquiry I was assured, that what I have mentioned, with two suits of uniform which he has at Sans Souci, forms the entire wardrobe of the King of Prussia. Our attendant said he had never known it more complete. When residing at Berlin, and particularly on public days, he made a great display of royal magnificence; but his ordinary mode of living was remarkably plain and uniform. His usual place of residence was the palace at Sans Souci, about a mile from Potsdam. His bed-chamber was beautifully furnished and provided with the appearance of a rich state-bed; but he always slept in a concealed bed, upon a hard mattress. He rose generally at five o’clock in the morning, and sometimes earlier. He dressed his hair himself, seldom employing above two minutes for that purpose; and pulled on his boots at his bed-side, never using either shoes or slippers. As soon as he was dressed, the adjutant of his first battalion of guards brought him a list of all the persons who had arrived at Potsdam or departed thence, with an account of any occurrences in the garrison. Having delivered his orders to this officer, he retired to an inner cabinet till seven o’clock. He then went into another apartment, where he drank coffee or chocolate, and perused his letters; and these, as he seldom received the most trifling proposal or petition except in writing, were always numerous. Having written notes on the margins of those which his secretaries were to answer, he carried with him such as he meant to answer himself, and continued with one of his private secretaries writing or dictating till nine o’clock, when he returned to the former apartment, where he was attended by three secretaries, and received their communications, or delivered to them his orders. At ten o’clock, the generals in attendance were admitted to his closet, where he conversed with them, or gave private audiences. At eleven he rose to the parade, where he reviewed his regiment of guards, and at the same hour all his colonels throughout the provinces were employed in the same manner. He then walked in the garden with the principal officers, and the rest of the company who were invited to dinner. At one, he sat down to table, seldom with more than twenty-four persons, and seldom occupying more than an hour. After rising from table, and conversing about a quarter of an hour with his guests, he retired to his private apartment, where he remained till five o’clock, when his reader waited upon him, who was generally one of his friends; and after reading about two hours, he joined in a musical concert till nine. He was then attended by a few of his learned friends, and favourite wits, whom he had invited to supper, and with whom he indulged in the utmost freedom of conversation till twelve, when he went to bed. Afterwards he omitted these suppers, and spent a longer time at dinner, where he used to eat with good appetite, and was particularly nice in regard to fruit. He was not less fond of Spanish snuff, of which he was accustomed to take inordinate quantities; and used a large golden snuff-box, richly ornamented with diamonds. He was much attached to dogs, and had generally beside him two or three Italian greyhounds, which he often caressed, and even kept small leather balls in his rooms in order to amuse them. He took little pleasure in the company of ladies, and rarely invited them to his private parties. His great and daily amusement consisted in musical concerts, at which he performed on the flute; but he confined himself chiefly to his own compositions, and those of his instructor Quantz; and even endeavoured, with his usual despotism, to regulate the musical taste of his subjects by authority.

His literary acquisitions, when compared with the disadvantages of his education, were considerable; but were, in a great measure, confined to the belles lettres, and to moral science. He possessed little knowledge of the Greek and Latin languages; and his acquaintance with classical authors was derived principally through the medium of French translations. Besides the works which have been already mentioned, he wrote letters on patriotism and on German literature; and left behind him in manuscript, Memoirs of his own life from the Year 1740 to the Death of Dresden—A History of the War of Seven Years—and, A History of the Transactions from the Peace of Hubersburgh; which were published after his death. His poetical compositions, consisting of his poem on the art of war, with a variety of odes and epistles, are collected under the title of Oeuvres mêlées du Philosophe de Sans Souci. He displayed, in his capacity of a ruler, more of personal ability than of political wisdom. He was constantly
Frederick aiming at the aggrandisement of his dominions, which he never hesitated to accomplish by the most unprovoked hostilities and unprincipled usurpations. He devoted, indeed, the last twenty years of his life to promote the prosperity of his subjects; but always upon principles of despotism, and in subserviency to ambitious schemes. In attention to his army, his government, and the internal policy of his kingdom, he was probably the most indefatigable sovereign that ever existed. His vigilance was unremitting, his industry unwearied. Every department of government was under his own immediate inspection; and the most minute particulars did not escape his observation. He conceived himself capable of every thing, and despised the talents of others. His numerous nominal counsellors he never consulted; and to his various ministers of state he delegated no portion of superintending power; but he would direct and almost perform everything himself. This intermeddling and controlling spirit was the great error of his administration; and rendered him always unequal to the management of commercial plans more pernicious than profitable to his state. He interfered even in judicial proceedings and literary questions; and made himself the supreme reviewing tribunal in all matters of equity and taste. He introduced a kind of military mechanism into every department; and “was constantly working mischief by working too much.” It was at the head of an army, that his talents appeared to the greatest advantage; and he must be acknowledged to have been the most accomplished warrior of modern times. He possessed an extensive knowledge of military science; and is ranked next to Maurice, Prince of Orange, and Gustavus Adolphus, as an inventor in the modern art of war. He introduced the use of flying artillery, and improved the oblique or angular order of battle, of which he profoundly studied the principles, and skillfully illustrated the efficacy, in not less than forty-two engagements. He was eminently distinguished by the promptitude and energy with which he executed his orders; and was always inconstant and capricious. Hence he was in his active exertion could ensure success. His personal intrepidity, his astonishing presence of mind in the moment of danger, and his patient endurance of hardships and privations, could not be surpassed; and in all his severest reverses, he discovered a mind that could not be subdued. Yet, with all his great endowments, there was little in his character to make him either amiable as a man, or venerable as a sovereign. Many of his faults may, no doubt, be traced to the despotical sentiments in which he was educated, and the military habits in which he lived; but there are traits in his character, which incontestably demonstrate, that his superior powers of intellect were united with a radical littleness of mind. His parsimony, ingratitude, cruelty, and injustice, are proved by a thousand instances. He examined every evening the bill of fare for next day’s dinner, squabbling with his domestics about the prices of every article, and paying with his own hands the expenses of his kitchen, stables, &c. He never bestowed one smile of favour upon the relatives of his friend De Catt, who had sacrificed himself in his behalf. To the family of the Wreches, who had befriended him in his imprisonment at the risk of their lives, he neither repaid the sums which they had pinched themselves to raise for his accommodation, nor distinguished them by any act of patronage. He broke the heart of his amiable brother, William Augustus, by harsh usage; and ruined the health and happiness of his youngest sister Amelia, by his barbarous persecution of her lover Trenck. He lavished, with unfeeling prodigality, the blood of his soldiers; and dismissed in time of peace his bravest officers, because they were not of noble extraction; though he had invited them to enter the army when he needed their services. He uniformly quarrelled with his most intimate associates; and often discarded, with the harshest injustice, those who had most faithfully spent their lives in his service. He commanded his favourite Secretary Galser to coin fifteen millions of ducats with an alloy of one-third of base metal; and, when the matter was discovered, he punished the unfortunate secretary with disgrace and banishment, as the author of the fraud.

He treated his literary companions and dependants with insolent familiarity, making them the butt of his sarcastic raillery; and, after encouraging them to similar freedoms, suddenly silencing them with his kingly authority, or with the most passionate abuse, and sometimes even with kicks and blows. He delighted to indulge in the most impious discussions; and bestowed the highest marks of his favour upon the most atheistical blasphemers. His general spirit in short was selfish and unfeeling; and, though he wished for the praise of virtue, he was ready to sacrifice every consideration to the love of fame, especially to the attainment of military renown. His intellectual powers, however eminent, were at least of that inferior order, which can submit to be guided by profligacy of principle, and stoop to seek assistance from dishonourable means. His abilities thus often appeared much greater than they were in reality; because, when wisdom failed, he had recourse to wickedness, and accomplished objects which would have baffled others, not because they were weaker, but because they were better men. Such, in fact, is often the chief superiority possessed by those who have received the appellation of Great; a “title, which is the less honourable, that mankind have generally agreed to bestow it, where gratitude was least of all due.” See Gillies’ View of the Reign of Frederick II. of Prussia; Tower’s Memoirs of the Life and Reign of Frederick of Prussia; Thiebault, Memoires de Frederic le Grand; Johnson’s Memoirs of the King of Prussia; Baron Bielfeld’s Letters; Observations on the Military Establishment of the King of Prussia, with an Account of his private Life; the King of Prussia’s Campaigns written by an Officer, and translated from the French; Anecdotes and Characteristics of Frederick the Great; Riesbeck’s Travels in Germany; Thomson’s Military Memoirs; Voltaire’s Idee du Roi de Prusse. FRESCO PAINTING. See Painting.

FRIBOURG, or FRIBOURG, a town of Switzerland, and the capital of a canton of the same name, is situated partly on a horizontal plane on the banks of the Sarine or Saane, and partly on the declivity of a ridge of rugged rocks, which form a singular contrast with the walls of the town and the towers of its convents and churches. When a stranger ascends the street of the Great Fountain in ascending from the Bains des trois Suisse, he can scarcely persuade himself that he is in the middle of a large town. The fortifications of Fribourg, consisting of lofty walls and towers, are about four miles in circumference, and inclose a large space, a great part of which is occupied with gardens and orchards. The descent to the town is on all sides extremely steep, and the street of the Great Fountain forms the roofs of the houses of the Court-chemin. A communi-
situated and the barren F. Its but at the low it the these. The See and be and tic. The seen not the. The Odet, natural of Augustins. The Bourguillon, M. Ignace. there is made between the two parts of the town by three bridges, from which there are very picturesque views. The most advantageous stations, from which an idea may be formed of the extraordinary situation of Fribourg, are the top of Schollenberg; the meadow situated beyond, the crucifix, which is seen in going out by the gate of Bourgillon; and the meadow which extends behind the Place d'Armes, near the gate of Romont.

The houses of Fribourg, which are raised above each other in regular gradation, are built with a grey sandstone from an adjacent quarry, and are in general neat and well built, though the town has a dull appearance. In the middle of the principal square, is the celebrated lime-tree, of great size and beauty, which is said to have been planted there in the 23d June 1476, by a soldier, on his return from the battle of Merat. For some years, this venerable tree has been losing its vigour. The town-house is an ancient edifice, which was built on the spot where the palace of the Dukes of Zuhrinngul formerly stood. The cathedral church, dedicated to St. Nicholas, was founded in 1283. Its tower is 326 feet high, being the highest in Switzerland. The bells are reckoned the finest in the country. The ci-devant college of the Jesuits, situated in the highest part of the town, affords, from its lofty towers, some of the finest and most extensive views. The other objects of interest at Fribourg are the gate of Bourgillon, situated between two precipices; the principal altar of the church of the convent of Augustins; the great reservoirs situated near the college of Jesuits; the mill of Motta, opposite to the convent of Maigrange; and the defile of Grotton. The cabinet of natural history belonging to M. Fontaine; the library, pictures, minerals, and philosophical instruments belonging to M. Joseph Praroman; the collection of books and MSS. relative to the history of Switzerland, belonging to M. Ignace Gady; and the small botanical garden of M. Odet, are worthy of the notice of travellers.

There is at Fribourg a seminary of priests; a gymnasion; schools for young persons in the convents of the Ursulines, and the Visitantines, and other inferior schools kept by the Franciscans and the Capuchins. There are 28 public fountains in Fribourg, of which the water is excellent. The inhabitants of the lower town, however, were formerly much afflicted with the goitre necks, but the disease is now less general.

The line of demarcation between the German and French languages passes through Fribourg. The inhabitants of the lower parts of the town speak German, and those in the higher part French, while the two languages are confounded in the middle of the town.

The principal manufactures of Fribourg are hats, candles, beer, earthenware, cotton cloths, &c. The chief promenades are in the square, planted with limes and in the Place d'Armes. Population 6,000. East Long. 6° 48', and North Lat. 46° 50'.

FRIENDLAND, BATTLE OF. See France, p. 648.

FRIENDLY ISLANDS, are situated in the eastern part of the Pacific Ocean, and lie between 161° and 21° South Latitude, and between 170° 30' and 185° 20' East Longitude. Their name expresses the firm alliance subsisting among their inhabitants, and the courteous behaviour which they testify towards strangers. Their number exceeds 150, but the greater part are mere rocks and shoals, or barren and desert spots. Nearly one half, however, are of considerable size, but the situation and extent of a few only have been ascertained. Sixty-one are marked on Captain Cook's chart, and the principal information concerning them is to be found in his voyages.

The most important are, Tonga, Tongataboo, or Amsterdam, discovered by Tasman in 1642, is situated in 21° 9' South Latitude, and 171° 1' West Longitude. It is rather of an oblong form, bearing some resemblance to an isosceles triangle, stretching in length from east to west, broadest at the east end, and about 20 leagues in circumference. It is a low land, nearly all of an equal height, never rising more than 80 feet above the level of the sea; and is surrounded by a reef of coral rocks, extending about 100 fathoms from the shore, and breaking the force of the sea before it reaches the land. A deep lagoon on the north coast, forms a secure and capacious harbour with a good bottom, but there is great scarcity of good fresh water in all these islands. This kind of rock appears also to be the basis of the island, as scarcely any other stone is seen either on the coast or in the interior. The rock projects in many places above the surface, but the soil is generally of a considerable depth, and in the cultivated parts is a loose black mould, apparently produced by decayed vegetables. The surface, at a distance appears to be clothed with trees of different sizes; but the tufted heads of the coco-palm produce the most striking effect. The largest tree is a species of fig; and the most common bushes on the uncultivated spots, are the pandanus, sannamoo, and several sorts of hibiscus. Though the climate is more variable than in countries farther within the line of the tropic, yet the foliage is only shed by degrees, every leaf as it falls being succeeded by another; and though the country exhibits little of that landscape beauty which is produced by a variety of hills and vallies, yet it is well laid out in plantations, and altogether presents the appearance of perpetual spring, and exuberant fertility. It abounds in the richest productions of nature; cocoa nut trees, bread fruit, plantains of fifteen varieties, bananas, shadocks, sugar-cane, a kind of plum, fig, and nectarine, yams white and black, the latter of which weigh from 20 to 30 pounds, gourds, Jesuits bark, bamboo, &c. and an innumerable list of uncultivated plants. The only quadrupeds are hogs, dogs, rats, and small lizards. The land birds, besides large domestic fowls, are pigeons, turtle-doves, parrots, parquots, cuckoo, king's fishers, rails, coots, fly-catchers, swallows; large bats, measuring from three to four feet between the tips of the wings when extended; a kind of green-coloured thrush, the only singing bird observed in the island; and several smaller birds. The water fowl are ducks, tropic-birds, herons, noddies, terns, small curlew, and large spotted plover. Nearly fifty different sorts of insects have been noticed, particularly very large spiders, and the most beautiful moths and butterflies; and of the reptile tribe, sea snakes about three feet long, scorpions, centipedes, and gummoes. The variety of fish is not so great as might be imagined; and the most common are mullets, silver fish, old wives, parrot fish, soles, leather jackets, allibores, homeoles, eels, pike, and devil fish; but there is great abundance of shell fish about the reefs and shoals, especially huge cockles, pearl shell and some other oysters.

* M. Dentrcasteaux was informed in 1793, that the horses and cows left by Captain Cook were all dead; but found that the hogs had been greatly improved by the cross with those of Europe, some of them weighing not less than 200 pounds.
FRIENDLY ISLANDS.

Neootabootaboo, and Kootahé, situated in South Latitude 15° 35', and 173° 48' West Longitude, were discovered by Schouten and Lemaire in 1616. The former is one of the larger islands in these seas, fertile and populous. They were visited by Captain Wallis in 1767, who called it Keppel's and Boscawen's islands; and in 1787 by Perouse, with whom the natives traded very freely, but had a more ferocious appearance than the more southern islanders.

Toofo, or Amattafoa, is situated about 12 leagues Tooffol north-west from Annamooka, and is about five leagues in circumference. It is thinly inhabited, but was reported to afford excellent water. It is chiefly remarkable as containing a volcano, the smoke of which was seen by Captain Cook at ten leagues distance; and which was described by the natives of the adjoining islands, as having been observed to ascend without intermission as far back as their memory and traditions could reach. They added, that it sometimes threw up large stones. It was at this island that Captain Bligh, after the mutiny of his crew, attempting with 18 of his people to procure a supply of bread, fruit, and water, was attacked by the natives, who killed one man, and wounded almost every individual of his company.

Three very considerable islands, or rather groups, were described to Captain Cook, larger than any yet mentioned, but they are still very imperfectly known to Europeans. Their names are Hamoa, Vavaoo, and Feejee. Hamoa, which is two days sail north-west from Vavaoo, is said to be the largest of all the islands, affording safe harbours, good water, and all the refreshments produced in the other places. Vavaoo, or Afootouou, is the name not of one but of a group of islands, of which little is known, except that they are abundantly stored with logs. Feejee, which is three days sail from Tongataboo, in the direction of north-west by west, and which is surrounded by a cluster of islands, abounds in hogs, dogs, fowls, and all the fruits and other vegetables found in these islands. Its breed of dogs are very numerous, and from them had been procured the few which were seen at Tongataboo, where they were not introduced till after 1775, and from which they had not been sent to any of the other islands in 1777. The natives of Feejee are of a darker colour than those of the other Friendly islands; more formidable in war, by their dexterity in the use of bows and slings; more savage in their manners, especially in the practice of eating the enemies whom they kill in battle; and more ingenious in their articles of workmanship, of which Captain Cook saw several specimens; such as variegated mats, earthen pots, beautifully chequered cloth, and clubs and spears covered with great ingenuity. These islands of Feejee appear to be the same which Tasman named Prince William's Isles, and were explored both by Captain Bligh in the Providence 1792, and by Captain Wilson in the Duff 1796. They reach northward as far as 13° 33' of Latitude, and to 19° 15', and lie in 178° West Longitude. Captain Barber in the Snow Arthur, visited the western part of the group in 1794, and was attacked by a number of the natives in canoes, who attempted to board the ship, and wounded several of the crew with their arrows.

All these islands which have been described, and all those which form the archipelago named Friendly, are under the government of one king, excepting Feejee,

* The most recent account of the Feejee islanders, is furnished by an extract from the Sydney Gazette, published in the South Magazine for 1810, page 601.
which is supposed to have become but recently known to the others; and whose warlike inhabitants, scarcely yet subdued, are greatly dreaded, and their friendship carefully cultivated by the other islanders. The capital and seat of government is Tongataboo; but the king resides occasionally on the other islands, particularly Hauao, the inhabitants of which appeared to be held in great estimation. The king was said to possess unbounded authority, and to have the absolute disposal of the lives and property of his subjects; but there appeared rather to be a kind of subordination, similar to the feudal system which formerly prevailed in Europe, as the more potent chiefs acted the part of petty sovereigns among their respective followers, and frequently counteracted the measures of the monarch. Tongataboo is divided into numerous districts, each of which has its proper chief, who dispenses justice, and decides disputes within his own territory, and who generally possess estates in the other islands, from which they receive supplies of provisions. This island is called by the natives the Land of Chieft, while the subordinate islands are stigmatized with the appellation of Lands of Servants. Its ordinary name also Tongataboo, signifies the Sacred Isle, because it is the residence of the Duatonga, the head of a family, supposed to have come originally from the sky, &c., and who seems to hold the station of high priest. The king bears the title of Toee Tonga, according to Cook; but according to later narratives, Duganaiboo. The utmost order and decorum are observed in his presence, and in that of the other chiefs. Whenever he sits down, all the attendants seat themselves before him in the form of a semicircle, leaving a sufficient space between them and him, into which no one, unless he has particular business, presumes to come. When any person wishes to address his majesty, he comes forward, and seats himself before him, delivering in a few words what he has to say. In direct opposition to European manners, it is accounted the greatest rudeness for any one to stand while he speaks to a superior; and even when the king is walking along, all who meet him must sit down till he has passed. When it is intended to do homage more directly, either to the sovereign or the chiefs, the person who pays the obedience squats down before the superior, bows his head to the sole of the prince's foot, which he touches with the under and upper side of the fingers of each hand, and then rising up retires. The crown is hereditary; but it was mentioned to Captain Cook by the reigning king, that if he were to fail in his duties, the collective body of the chiefs and the people would authorize the commander of the forces to depose him, and put him to death. This very prince dying before his son was of age, the sovereignty was wrested out of his family by a powerful chief, after it had continued about 140 years in one line.

The king seems to be considered as lord of the soil, and upon him devolves the landed property of every subject at his death; but it is customary for the sovereign to grant to the eldest son of the deceased, upon condition of providing for the other children. The different classes of the chiefs are very numerous; but few of them possess extensive districts of territory. They are called by the people, "the lords of the earth," and exercise a despotic authority over their respective vassals. The most profound silence and respectful attention are observed, when any of them addresses a body of their dependants; and no symptoms of dissatisfaction or disobedience were ever perceived among the latter. Every thing in their possession is considered as belonging to the chief, who takes them without ceremony whatever he may need. However scanty their supply of provisions, they are required to cook a portion of it for his use; and, in a time of scarcity, he often sends his attendants round the district, with orders for a certain quantity to be prepared in a limited time, which he stores up for himself and his household, while the wretched people are reduced to subsist on the coarsest roots, or to beg back a little of their own fruits, to keep them from starving. Nor do the lower classes merely labour for themselves and their respective chiefs, but they are frequently sent, as a species of tax or tribute from their lords, to work on the lands of the sovereign; and, in addition to all these arbitrary exactions, they are treated by their superiors with the utmost harshness and brutality.

The inhabitants of the Friendly islands acknowledge a supreme divinity residing in the heavens, and directing the elements; but they worship at the same time a plurality of deities, each of whom has a peculiar administration, one presiding over the wind, another over the sea, another over the rain, &c. They ascribe earthquakes to the motions of a giant, who supports their island on his shoulders; and, as they imagine the shaking to be occasioned by his becoming drowsy, they hasten to shoot as loudly as possible, and to beat the ground with sticks, in order to rouse him, lest by his stumbling through sleep he should throw the island from his shoulders. Each district also worships its appropriate god; and even every individual is supposed to have a particular spirit attending him, who sends afflictions and maladies when he is displeased, and, when irreconcilable, occasions death itself. To render him propitious, the relations or dependents of the patient frequently wound themselves, or cut off their little finger, and sometimes even some of his wives, children, or domestics, are put to death. They consider the power of their deities as confined to the present life, and their evil deeds as meeting always with punishment upon earth. Hence they employ every method to render them propitious, applying to them for a continuance of plenty, and supplicating their aid in time of suffering. They solemnly implore the blessing of the supreme divinity when they plant their crops, and express their gratitude when they gather them. Hence there is an annual assembly of the chiefs of Tongataboo, and of all the neighbouring islands, at the dwelling of Duatonga, the high priest, to offer the first fruits of their fields to him, as the minister and representative of the god who causes fertility. They do not appear to worship any visible part of creation, or any idols formed by their own hands; nor do they offer any animal victims, although on certain occasions they sacrifice human beings.

They have no priests, but every man presents his own offering. They discover a wonderfully just idea of the immortality of the soul, and in some degree also of its immaterial nature. They believe, that, immediately after the death of the body, the souls of the chiefs are swiftly conveyed to a distant island, where they are no longer subject to death, where every kind of food is spon-

* The missionaries were in like manner called by the natives of Tongataboo, "The men of the sky," because observing that the sky appeared to touch the ocean in the distant horizon, and knowing that they came from a great distance, they concluded that they must have come through the sky to arrive at their island.
They should be treated with respect and kindness,

but it is customary to apply freely for provisions to those

who have plenty; and it would be accounted a great

breach of hospitality to refuse, while any stores remain-

ed. Should any one be sitting with his family at meal

before his house, a stranger passing by will sit down

among them without ceremony, and expect a share of

the meat.

The houses of the natives are constructed with little

habitation ingenuity or taste, and are, properly speaking, nothing

more than thatched roofs or sheds, supported by posts and

rafters. The floor is raised with earths, smoothed and

levelled, and covered with thick matting. Some of them

are open on all sides, but generally they are enclosed on

the weather side with strong mats, or branches of the

cocnut tree interwoven with each other. A thick mat,

about three feet broad, bent into a semicircular form,

placed edgeways, and sometimes fastened to the beams,

encloses a space as a bed-room for the master of the

family and his wife; while the rest sleep upon any part

of the floor, the unmarried men and women lying in dif-

ferent places; and if the household is large, there are little

huts adjoining for the children and servants. The habi-

tations of the lower class are only wretched hovels, scarce-

ly sufficient to shelter them from the weather; but those

of the chiefs are more comfortable and commodious, their

ordinary dimensions being about 12 feet in height, 20 in

breadth, and 30 in length. The house of the second

chief in Tongataboo was 50 feet in length; and of an

oval form. One large and lofty post was fixed in the

centre, and an oval ring of lesser ones were planted round

it at equal distances, forming the sides of the building.

Upon those posts, layers were fixed, and from these, raft-

ers were extended to the pillar in the middle, thus unit-

ing the whole edifice. The inside of the roof was orna-

mented with beautiful matting, which was protected by

an outer thatch of plantain branches, interwoven like

basket work. In rainy weather, screens of matting, made

of the cocoa tree, were fastened to the outer posts, but

the door-way was left open night and day. The floor

was covered with beautiful matting, so close a texture

as to be impervious to insects. The furniture generally

consists of some wooden stools, which are used as pil-

lows; two or three wooden bowls for holding their fa-

vourite liquor kava; baskets of different sizes, into which

they put their tools; fish-hooks, &c.; a bundle or two of

cloth, a few gourds, and cocoa-nut shells.

They discover more ingenuity in the construction and

Canoe ornaments of their canoes, which are the most perfect of

their mechanical productions, and which surpass in neat-

ness of workmanship all others in the South Sea. They

are built of several planks of the bread-fruit tree, sewn

together with cocoa-nut line in a neat manner, that

they appear on the outside as if they were composed of

one solid piece. The fastenings are all on the inside,

and pass through kants or ridges, wrought on purpose on

the edges and ends of the different boards. They are of

two kinds, double and single. The single canoes are

from 20 to 30 feet in length, about 22 inches broad in

the middle, and 18 inches deep, with the head resem-

bling the point of a wedge, and the stern terminating in

a blunter point. At each end is a kind of deck, extend-

ing one third of the whole length; but they are open in

the middle. They have all out riggers, and are some-

times navigated with sails, but more generally with padd-

les, the blades of which are short, and broadest in the

middle. The double canoes are composed of two vessels,

about 60 or 70 feet long, 4 or 5 broad in the middle, and

3 deep, exclusive of the deck. These are fastened toge-

ther, about six or seven feet asunder, by strong cross

beams, secured by bandages to risings on the open mid-
FRIENDLY ISLANDS.

FRIENDLY Islands.

FRIENDLY Islands.

The only tools which they possess are hatchets or adzes of a smooth black stone; augers made of shark's teeth; rasps composed of a rough fish-skin fastened on flat pieces of wood; and knives made of sharp shells; yet with these defective instruments they produce many articles of neat and curious workmanship, which at once testify their ingenuity and patience.

Their weapons, such as clubs, spears, and darts, are made of hard wood, curiously carved and ornamented. Their stools or pillows, which are made of brown or black wood, are finely polished, and frequently inlaid with ivory. Their cordage is made of the fibres of the cocoa-nut husk, from which they form four or five-inch rope, laced exactly like those of Europe; and fishing lines as strong and even as the best cord. Their small hooks are made entirely of pearl shell, but the larger ones are only covered with it on the back; and the points of both kinds are generally of tortoise-shell. They have small nets of the most delicate texture; and their baskets, made of the same cocoa-nut fibres, are as once durable and beautiful, being generally composed of different colours, and studded with beads made of shells or bones. Their manufacture of cloth and mats, which is the chief employment of the women, is executed with wonderful skill. The cloth is made from the slender stalks and trunks of the paper-mulberry, which rarely grows above seven feet in height, and four fingers in thickness. From these stalks they strip the bark, which, after scraping off the exterior rind, they roll up and macerate in water. It is then beaten with a square wooden instrument, sometimes smooth, and sometimes full of coarse grooves. This operation is frequently repeated; and the pieces, which are generally from four to seven feet in length, and half as broad, are then laid out to dry. These pieces are joined together with the glutinous juice of a berry, and, being then placed over a large piece of wood with a sort of stamp beneath them, are rubbed hard with a bit of cloth dipped in the juice of some bark, which gives to the surface a dry brown gloss, while the stamp at the same time makes a slight impression. This glazing renders the stuff both more durable, and capable of resisting rain. The finer sorts, in addition to this operation, are dyed of different colours, and stamped of different patterns. In this manner they proceed, joining and staining, and gluing spare bits upon any holes or thin spots, till they have produced a piece of cloth of the requisite length and breadth. The mats are of seven or eight different sorts, and excel those of most other countries both in texture and beauty. Some are intended merely for ornament, and are made from the tough membranous part of the plantain tree; others are worn as a part of dress, and are generally prepared from the pandanus; and a coarser kind for beds and sails is formed from a plant called evarra.

The food of these islanders consists principally of vegetables, such as cocoa nuts, bread-fruit, plantains, yams, and tarros, a root resembling a carrot. Their chief articles of animal food are hogs, fish, and fowls, which are, however, only occasional dainties, reserved for persons of rank; but the common people frequently eat rats, which abound in all the islands. Their food is generally dressed by baking, and they make several palatable dishes from different sorts of fruit. They sometimes boil their fish in the green leaves of the plantain tree, tied up so as to form a bag, which holds both the fish and the water, thus producing a kind of fish soup. Hogs are generally baked whole, in holes dug in the earth, having the bottom covered with red hot stones about the size of a man's fist. Some of these stones, wrapped in leaves of the bread-fruit trees, being at the same time introduced into the belly of the hog, and the carcass having been placed on cross sticks, and covered with leaves, the whole is closed around with earth, and left, without further attention, to the influence of the heat. They are not very cleanly, either in their cookery or manner of eating; and, except in families, seldom sit down in companies to a sociable meal. Their usual drink at meals is water, or the milk of the cocoa nut; but they use at breakfast, or, as a morning beverage, a favourite liquor named kava, which is prepared in a manner sufficiently disgusting to European feelings. The kava is a species of pepper, which is carefully cultivated around the habitations, and which generally grows to the height of a man. The root of this plant, after being properly cleaned, is split into small pieces, which are distributed among the young people who have clean teeth, to be chewed. Each of these has a leaf placed before him, on which he lays his portion of the masticated root; and, when it is all chewed, the contents of the leaves are emptied into a large bowl. It is then mixed with a proper quantity of water, and squeezed hard with the hands, to press out the liquor; then put three or four times through a fine strainer, made of the inner bark of a tree. It is next served out in cups, made of plantain leaves, and about a quarter of a pint is put into each; but they often continue to drink in considerable quantities. When taken by some of Captain Cook's sailors, it operated like spirits, producing intoxication, or rather stupefaction; but seemed to have very little effect upon the natives.

The ordinary dress of both sexes of the better class consists of a piece of cloth or matting, several yards in length, wrapped round the body, and fastened below the breast by a peculiar kind of knot, from which it hangs loose down to the knees; and, being tied close with a belt, is sufficiently long for the upper part to be thrown over the shoulders. This, however, is a costly dress, and is not always worn even by the chiefs. That which is more generally in use, is made of the leaves of the gee plant, which are very broad and strong, and which, being finely shredded, are thickly entwined in a belt, and fastened round the waist, from which they hang down to the middle of the thigh like a full fringe. This, with the addition of a few strings of flowers, is commonly the sole dress of the women in their festive dances. The inferior class, however, often wear only the maro, which is a belt about four or five inches broad, passed between the thighs, and fastened round the waist; and, especially
when engaged in war, in fishing, or any active occupation, this covering composes the whole of their dress. Both men and women occasionally defend their faces from the sun with little bonnets, made of different materials. The ornaments, also, as well as the dress of both sexes, is the same, and consist chiefly of necklaces made of the fruit of the pandanus, and various odoriferous flowers, or of small shells, sharks' teeth, the wing and leg-bones of birds pendant on the breast; rings of tortoise-shell on the fingers, and several of these joined together, forming bracelets, on the wrists; a polished mother-of-pearl shell, or a ring, on the upper part of the arm; and cylindrical bits of ivory, or of reed stuffed with a yellow pigment, as ear-rings. They dye their hair of different colours, brown, purple, or orange, and wear it in a great variety of ways, sometimes growing to its full length, sometimes short on one side and long on the other, sometimes entirely cut away except a single lock on one side, or on the top of the head. The beard is cut short, and sometimes shaved close with sharp shells. Both sexes pluck the hair from their arm-pits, and around their body, especially the head and shoulders, with cocoa-nut oil. The women rub a fine yellow powder like turmeric over the whole of their bodies, and have a few blue lines tattooed on the inside of their hands. The men are stained or punctured with these lines and figures from the middle of the belly half way down the thighs; and are also partially circumcised, or rather superceded, by cutting off the upper part of the foreskin. They are all remarkably clean in their persons, and bathe frequently in the ponds, which they prefer to the sea, as they reckon the salt water injurious to the delicacy of their skin.

Polygamy prevails among the Friendly Islanders without any apparent limits; and the power of divorce seems to be equally unrestrained. Every man may take as many wives as he can maintain; and also dismiss them when he pleases. The greater part of the commonalty content themselves with one; but the chiefs have generally from four to eight. The young women have no liberty of choice in their matrimonial connections, but are disposed of by the father or his representative. They pride themselves much upon their virginity; and, as a token of that state, wear their hair uncut till they are married. The daughters of the chiefs are, from their birth, placed under the care of women, who may be called iudens; and, even after marriage, similar attendants are provided by the husband. The forms of courtship and marriage are sufficiently simple. The intending husband makes known his wishes to the parents of the other party, sending at the same time a present of provisions. If the present is accepted, which is not always done at the first offer, his proposal is considered as favourably received; the affair is then communicated to the daughter, who, having no power, never attempts to refuse. Upon a day being fixed, the bride is brought in her best apparel, at the head of a large company of females, one of whom, taking her by the hand, places her by the side of the bridegroom, who is waiting with his friends before his house to receive her; and the ceremony concludes with a feast and a dance.

Sometimes marriages are contracted, like the Jewish espousal, many years before the consummation of the nuptials. Where there are several wives, the children take the rank of their respective mothers; and, in all domestic cases, probably owing to the frequency of divorce, and life of illicit intercourse, family dignity descends through the female. Their mode of domestic life, especially among the chiefs, is much after the patriarchal form; and the younger and inferior branches surround the head of the family in one household, and in the greatest harmony. There is much social intercourse among the members of the family, especially in the evenings, when they retire to their matings, which is commonly done about seven o'clock; but instead of then going to sleep, they are accustomed to converse till ten or eleven with much cheerful pleasantness and shrewdness of remark; and so fond are they of chatting in this familiar manner, that, should one chance to awake during the night, and find another in the same predicament, they will renew the conversation for an hour, and perhaps rouse some of the rest to join in it. Yet, with all this freedom of intercourse, there is a strict observance of proper respect, and even of ceremonious politeness; and the behaviour and language of the higher classes are thus refined and improved above the lower, in the same proportion as in civilized countries. * This may be exemplified by the orderly manner in which the household of a chief is arranged and served at breakfast, which consists in drinking kava, and eating baked yams, &c., and is taken at day-break, as soon as the family rise from bed. The company forms a large circle, sitting cross-legged before the chief, on each side of whom stand the principal servants to direct the preparation of the kava, by the younger persons, while the rest of the company are silently forming their temporary cups of plantain leaf. Persons appointed to the office, then rising from the circle, approach the bowl with those plantain vessels; and when the distributor of the liquor has filled one of them, he asks, "whose kava is this?" The principal domestic replies, "take it to such a one," and the person, whose name is pronounced, claps his hands, as a signal to the waiter where to convey it. These waiters conduct themselves in the most becoming and regular manner, arranging their apparel with the greatest neatness, walking with all possible grace, and presenting the cups with ceremonious politeness. Other servants, during the preparation of the kava, are busily employed in baking the yams, which are brought in as soon as the liquor is distributed, and placed before the company, who eat their portion, and talk together as they please; and, in all the different steps of the process, the word of command is given and observed with an exactness and attention resembling a regiment at parade. At this entertainment they often continue from day-break to noon, and then lie down and sleep two or three hours. It is a favourite luxury of the principal people, to have their bodies and limbs, while they are asleep, thumped or beaten with the fists of women, who relieve each other during the operation. After rising, they proceed, like too many of the higher ranks in most countries, to contrive amusement for the day.

* Their manner of bestowing a present, as mentioned by the English Missionary, who resided among them at Tungatuboo, shows a high degree of refinement, and may be considered as a parallel to the complimentary style of the Orientals. "If he sent me a pig, those who brought it would say, they had brought a pig, but it was very small, and intended for the servants, if I would permit them, for Mulk Aamair's sake, to accept it." Compare 1 Sam. xxv. 27.
One of their most favourite amusements is bathing, in which they generally indulge two or three times a day; and they have different water games, in which both sexes join. Two posts are fixed about a hundred yards distance from each other, in a depth of water about four feet; and the company, dividing into two parties, a large stone is placed between them. The contest is, which side shall first drag the stone to their own post; and the divers generally remain a considerable time struggling around the stone, at the bottom of the water. Another bathing diversion consists in going out at high water, when the sea rolls in on their flat shores with great force, and then ride in on the swell, steering themselves on the top of the wave with the utmost dexterity, stretching out one hand like a prow, and guiding themselves with the other like a rudder. When a spectator would apprehend that they must insally be dashed lifeless to the beach, they will turn on one side with surprising agility, and darting through the wave, swim out to sea to renew the sport; or, if tired of the amusement, will shoot through the resulent surge, and land in perfect safety. Another favourite diversion, especially of the chiefs, is rat shooting. The cocoanut, roasted and chewed, is strewed by the servants near the holes of these animals; and the sportsmen take their stand with bows and arrows. By making a squeaking noise like that of the rats, they entice them to come out, and, while they are feeding on the nuts, they take aim alternately, and whosoever kills most in the same number of shots wins the game. Wrestling and boxing matches furnish another source of entertainment; in both of which exercises they have been generally conquerors, when engaged with Europeans, and are particularly remarkable for the good humour which they preserve when worsted. Though a very active people, they frequently spend whole days in luxurious indolence, walking among the plantations, or collecting in one another's houses for the sake of conversation; but these more sedentary days are generally concluded by dancing and singing, which is their most favourite amusement. The chief sends through his district, collecting about 40 or 50 young persons, of both sexes, to dance by torch light with his regular attendants. The women, on these occasions, are clothed with a thin drapery, having their necks and shoulders encircled with wreaths of flowers, and their dark ringlets bespangled with the whitest and most aromatic blossoms. Their dances are said to be beautifully diversified, and to be performed by companies of eighty or a hundred, with the greatest promptness, regularity, and gracefulness of movement. This amusement is frequently continued till midnight, and sometimes till morning, one set retiring to rest, while another rises to dance. It is their great pastime on all occasions, and generally concludes even their ceremonies of mourning. It is however so often performed with little regard to decency, and is generally an incentive to the most licentious excesses. Their music is very simple and pleasing, but extremely monotonous. Their songs are lively and melodious; but their instruments are very defective. One, composed of unequal sized reeds, resembles Pan's pipe. Another is a flute of bamboo, about 18 inches in length, closed at both extremities, with a hole near to each end, and four others in the middle. Into this instrument they blow with one nostril instead of the mouth, and, with only three notes, produce a pleasing simple music. The principal instrument is a kind of drum, formed of a log of wood, hollowed throughout with a long narrow aperture, laid lengthwise upon two solid pieces, and beaten with bamboo of different lengths, so as to yield a sound according to the length of the stick.

They have a variety of ceremonies to express their grief for the dead; but they are of such a nature, that it is difficult to decide, whether they give greater proof of humanity or barbarity. When any of them die, he is wrapped up in mats and cloth, and interred in burying places called Fia-tooks. These are large inclosed spaces, having in the middle a lofty funeral pile, of a pyramidal form, around which the bodies of the chiefs, (for the inferior people have no particular spot of interment) are collected for many generations, and arranged in a style of rude but solemn dignity. When the deceased is a person of distinction, some of his wives, or other relations, are strangled at the moment that his corpse is deposited; and the nearer relatives, in every case, inflict upon themselves many bloody marks of sorrow.

The most common way of testifying grief, is to strike their faces and breasts with their hands: and many of them have scars on their cheek bones, resembling a circle produced by burning, occasioned by the frequent abrasion of the skin. At other times they strike a shark's tooth into their foreheads, beat their teeth with stones, and even thrust spears through their cheeks, or into their sides and thighs. Around the graves of their kings and principal chiefs, they often mangle one another in a kind of bacchanalian frenzy, of which the following account is given by one of the missionaries, who resided lately among them for several years. "The space round the tomb was, on this occasion, a palaestra for savage gladiators. Hundreds ran about it with ferocious emulation, to signalize their grief for the venerable chief, or their contempt of pain and death, by inflicting on themselves the most ghastly wounds, and exhibiting spectacles of the greatest horror. Thousands, ere the period of mourning was over, fought with each other, and cut themselves with sharp instruments. It was an awful scene indeed! Night after night we heard, for some weeks, the horrid sound of the conchshell rousing these deluded creatures to these dreadful rites of mourning for the dead; and shrieks and clashing arms, and the rushing and violence of the multitude, re-echoed round our abode, and rendered it a scene of continual horror and alarm."

The natives of the Friendly Islands seldom exceed in stature the common size of Europeans; and are generally strongly built and well proportioned in their figure, their shoulders are broad, and their whole form conveys the idea of strength rather than of beauty. They have good eyes and teeth, and are free from that uncommon thickness about the lips, which is found among the inhabitants of the other islands in the Pacific. Their hair is thick, straight, and strong, though sometimes bushy and frizzled; and its natural colour is black, but many of them stain it of a white, brown, purple, or orange hue. There is observable among them a great variety of features, many Roman profiles and European faces; and the only general likeness which characterizes them, is a fulness at the point of the nose. The general colour of their skin is a cast deeper than copper brown; but several of them have a true olive complexion. The greater part of the people have a dull hue, and a degree of roughness on the surface of the body, especially where
It is uncovered; but, in the higher classes, there is a softer and clearer skin, with a tendency to corpulence. The women are distinguished from the men, less by their features than by their form. Sometimes, indeed, their countenances are both delicate and expressive; but they are more remarkable for the elegance of their figures, which are usually well proportioned, and often perfect models of female beauty: The smallness and delicacy of their hands, seems to be their principal distinction. Both sexes are strong and active, and have a very graceful mien, and great firmness of step when they walk. Few natural defects or deformities are to be seen among them; and they appeared to all the navigators, who have visited their coasts, to be remarkably healthy. Though extremely attentive to personal cleanliness, they are most liable to cutaneous diseases, particularly to the tetter or ring-worm, which leaves whitish serpentine marks upon their bodies. They are frequently affected also with tumours in the testicles, and swellings on their legs and arms; but a species of venereal disease, which covers their bodies, and particularly the face, with broad ulcers, is the worst of their maladies. They have always evinced a very pacific and friendly disposition towards strangers, and observed the greatest uprightness in their traffic; but all of them, of whatever age or sex, are remarkably addicted to theft from their European visitors, and display the utmost dexterity, and sometimes murderous ferocity in the practice. When detected and punished, they showed the most complete insensibility, both to the shame and bodily suffering inflicted on them. The utmost mildness and good nature is depicted on their countenances; and they preserve a degree of self-command in their conduct, very unusual in the savage state. They are, at the same time, cheerful, open, and good-humoured; and the females particularly are unusually merry and talkative. They were described, in short, by their first European visitors, as a people not only adorned by all the gentler virtues, but also as possessing many of the most estimable qualities of human nature; but more recent information proves them to be capable of the most ferocious excesses, and overturns all the declamations, founded upon their character, in favour of un civilized society. In their wars, particularly, they present all the features of barbarians; and the fiercest savages of America are not more merciless towards hostile tribes, than these friendly islanders are to one another in their intestine commotions. One of the common modes of warfare among them is to "tooietang," as they express it, that is to come upon the adversary by surprise, to massacre in secret, to carry off plunder, to cut down the plantains and cocoa-trees, and to commit every species of devastation. Women, children, and prisoners, are murdered without mercy; and the dead bodies, after being exposed to the most brutal indignities, are roasted and devoured with voracious satisfaction. Their cruelties are perpetrated with the most wanton levity; and more than ordinary barbarism was witnessed by one of the English missionaries, who had adopted their customs, and joined in their expeditions. "Spectacles too shocking for humanity to contemplate, soon sickened my sight, and sunk my spirits: I beheld, with shaking horror, large stacks of human bodies piled up, by being laid transversely upon each other, as a monumental trophy of the victory. Proceeding a little farther, a horrid spectacle almost froze my blood. It was a woman in a sitting posture, with folded arms, holding a child to her breast, as in the act of suckling it. Upon approaching them, I found both the mother and child cold and stiff with death. The enemy had killed them while in this posture, and indulged their savage revenge in amusing themselves with placing the dead bodies in this affecting attitude." In the course of the civil war to which this extract refers, several of the missionaries stationed in Tongataboo were cruelly butchered, while harmlessly looking upon a victorious party, who were passing their habitation; and while the facts above related clearly shew how unadvisable it is to establish Christian teachers where their persons are exposed to lawless violence, they prove, at the same time, how much the humanizing influence of their doctrines is needed, by those who have been most highly extolled as the inoffensive children of nature. See Cook's Second Voyage round the World, 4to. vol. i. p. 211; Cook's last Voyage round the World, vol. i. p. 141, 267, 285; Authentic Narrative of four years residence at Tongataboo; Wilson's Missionary Voyage in the Ship Duff. (q)

FRIESLAND, West, in ancient times called Frisia, one of the seven united provinces, is bounded on the north by the German Ocean; on the south by Overysel and the Zuyderzee; and on the east by Ommeland, Drenthe, and Overysel. It lies between 52° 43' and 53° 30' of North Latitude, and between 6° 38' and 6° 5' of East Longitude from Greenwich; extending from 10 to 13 leagues from north to south; and nearly the same distance from west to east. It is divided into four quarters; namely, Oostero, Westero, Zevenwelde or Seven Forests, and the islands on the north coast. It contains about 100,000 inhabitants; and sends five of the 55 representatives, who compose the assembly of the states-general. Oostero, the north-east quarter, is divided into 10 districts; Leeuwerderdeel containing 14 villages; Ferwerderdeel containing 11; West Dongerdeel 14; Kollumerland 6; East Dongerdeel 14; Dantumadeel 12; Tauterksteradeel 12; Smallengerland 7; Idaarderadeel 8; Anwerderadeel 6; Westero is divided into nine districts; Het-bilt, containing 9 villages; Harlingen 9; Wonseradeel 27; Waterland 9; Wymbritzerdeel 28; Hennepderdeel 12; Bardeel 16; Menaflumeradeel 12; and Franekeradeel 13. Zevenwelde is divided into 10 districts; Gaasterland containing 8 villages; Haskerland containing 7; Utingeradeel 7; Doniwerstal 14; Opsterland 13; Angwiren 5; Schoterland 12; Stellingwerfer-Oostende 12; Stellingwerf-Westende 20; and Lemsterland 5. The largest of the islands on the north coast of the province is Ameland, which is about four leagues in length, and one in breadth, and contains several villages, Hol lum, Balkum, Nesse, &c. The principal towns in Friesland are situated on the north-west coast, namely, Leeuwarden, the capital of the province, a well built town, about 25 leagues N. E. of Amsterdam, and containing 2000 inhabitants; Franeker, a small but handsome trading town, the seat of an university, and about 34 leagues west of Leeuwarden; Harlingen, a fortified and populous place, with a convenient harbour, but of difficult access, about 20 leagues north-north-west of Amsterdam, and containing 7000 inhabitants; Dockum, an ancient and neatly built trading town, situated in a fine corn country, containing 3000 inhabitants, and about four leagues north-north-east of Leeuwarden; Bolsward,
FRIESLAND.

Friesland, a small but ancient town, celebrated for its manufacture of baize or light woollen stuffs, containing 2000 inhabitants, and about 43 leagues south-west of Leeuwarden; Workum, a small open town, surrounded by a ditch, and celebrated as the birth-place of Lambert de Bos, about 7 miles south-west of Bolsward; Staveren, anciently the residence of the Frisian kings, now an inconsiderable place in a marshy country, near the south-west point of the province, and about 7 leagues south of Harlingen; and Slooten, a small, but regular, and trading town, surrounded by lakes, and 4 leagues east of Staveren.

The ancient inhabitants of Friesland were distinguished by the obstinate defence which they made of their liberty, against the power of the Roman emperors, and by their repeated attempts to shake off the yoke of their conquerors. After the death of Drusus, by whom they had been compelled to submit, and after having been 40 years in subjection, they expelled the Romans from their province, and even made encroachments on the territories of the empire. Their ambassadors repaid with the utmost boldness, to the court of Nero; asserted in his presence that they were excelled by no nation in equity and valour; professed their desire to live in friendship with the Romans, but not in subjection; and even demanded a place in the public theatres, to which they understood they had a right as ambassadors. Though driven back by the Romans, and obliged to confine themselves within their ancient boundaries, they continued for a long series of years to maintain their independence as a state; but, towards the decline of the empire, they fell under the domination of the Franks. About the beginning of the 8th century, Adalgise, who is considered as the first Christian king of Friesland, refused to pay homage to the Franks, and a war ensued. Radbode, his son, was defeated by Pepin; but so recommended himself by his valour to the esteem of the conqueror, that he received his daughter in marriage. Charles Martel, afterwards attempting to reduce the Frieslanders, was routed with great slaughter, and left them for a time unmolested. Returning, however, with a numerous army, and wearing them out by a succession of bloody battles, he compelled them at length to acknowledge his superiority, but not his sovereignty. Under Charlemagne they were still further subdued, and obliged to pay an annual tribute of thirty pounds of silver. As now a province of the Franks, the country was governed by counts or lieutenants, with the title of Podesta or Podestad; but, under their first governor Forteman the Great, they rendered such essential services against the Saxons, that Charlemagne exempted them from every mark of servitude, and left them free to choose their own form of government. They made no alteration, but continued Forteman in his office. About the middle of the ninth century, the province was repeatedly ravaged by the Normans and the Danes; but the valour of the people finally prevailed, and cleared their coasts of every invader. In the year 935, William, Earl of Holland and King of the Romans, bestowed many valuable privileges upon the inhabitants of Friesland, in hopes of gaining their affections, and persuading them to acknowledge his sovereignty. But the Podestad Sierdama, supported by a powerful body of his countrymen, declared that they would never betray their country to gratify an emperor, and struck a medal expressive of their determination to be free. This was construed as an affront by William, who twice led his army into the province, and was slain in his second expedition. One of the most warlike of the Friesland Podestads was Martena, from whom many of the noble families in the province trace their descent. This active chief baffled all the exertions of the Hollanders to gain possession of the country, and frequently carried his victorious arms into the territories of the invaders. After his death, the election of a successor gave rise to two violent factions, whose contentions filled the country with confusion; and, together with the pressure of a war with Albert of Bavaria, reduced the province to so low a state, that several persons refused to accept the office of Podestad. At length, to please both parties, two governors were elected, one from each faction; but this measure, instead of promoting reconciliation, served only to aggravate their animosities, till at last they had recourse to arms, and seemed to be bent only upon extirpating one another. These dissensions reduced Friesland to the verge of destruction, and were the means of its becoming subject, in 1417, to Sigismund, Emperor of Germany. At the termination of a long war between Jean of Bavaria, and Philip the Good of Burgundy, the province of Friesland was granted by the House of Bourton. It became subject afterwards to the house of Austria; and never recovered its freedom till the general revolt in the Netherlands gave birth to the republic of the United States, of which, since that period, it has formed one of the seven provinces. The inhabitants are said still to retain that ardent love of freedom, by which their ancestors were so distinguished, together with many of their ancient customs and modes of living. Even their dialect and accent are said to be peculiar, and the language of the peasantry, in particular, is often unintelligible to the other inhabitants of the Low Countries.

The province of Friesland is a flat country, and the north-west coast particularly being below the level of the sea, is secured against the encroachments of the ocean by very strong dikes, constructed and preserved at a vast expense. In former times, when the care of these dikes was left to the proprietors of the adjoining estates, they were often insufficient to prevent decay, and the most destructive inundations were frequently the consequence of this neglect. In order to preserve themselves and their effects in such calamities, the inhabitants, in the want of natural sand hills, constructed circular eminences about twenty or twenty-five feet in height, upon which at length they gradually built their habitations, so that many of the towns and villages of the province are now situated on these artificial mounds. Since the year 1570, when the dikes were all raised and strengthened at the public expense, these irruptions of the sea have been less frequent and fatal.

Friesland very much resembles the provinces of Holland in its climate and soil. The country has been originally full of marshes; and many lakes are still found in the south-west districts; but in the south-east are several extensive heaths and woods. The whole country is now intersected with canals, which at once carry off the superfluous water to the sea, and facilitate the intercourse of traffic. One of them extends from Harlingen to Lieuwarden, and thence by smaller branches to Groningen; and another passes from Slooten to a small gulf on the south coast. The north-west districts abound in excellent pastures; and, in these quarters, immense quantities of butter and cheese are produced. The cow-pock is said to have here been known among the peasantry from time immemorial. Besides
excellent cows, sheep, and oxen, number of large horses are reared in these pastures, and sent for sale to Germany and other countries. In the more elevated parts good corn land is found, and the wheat which it produces is greatly esteemed for the whiteness of its flour. Barley, peas, and potatoes, also are commonly raised; but oats and hemp are the principal products. The inhabitants, however, derive their chief support from the fisheries, which are numerous along the coast. Friesland is famed for its woollen stuffs, and still more for its linens, which are said to be the finest in Europe. The fuel principally used in the country is peat or turf, but of an inferior kind to that which is found in Holland. See Modern Univ. Hist., vol. xxxi.; and Playfair’s Geography.

FRIESLAND, EAST, a principality in the circle of Westphalia, is bounded on the north by West Friesland and the German Ocean, on the east by Oldenburg, and on the south by the bishopric of Munster, and on the west by Groningen. It lies in 53° 20’ North Latitude, and 7° 20’ East Longitude, extending 40 miles from north to south, and nearly the same distance from west to east. It contains several towns, and about 103,000 inhabitants. The principal town is Aukrug, in the centre of the country, defended by a castle, surrounded by a marshy territory, and by forests full of game, formerly the prince’s residence, and containing 2000 inhabitants. Norden or Noorden, an old, unfortified town, near the north-west extremity of the country, about three miles from the coast, and 17 north of Embden, has a tolerable harbour and a little trade. Embden, a flourishing sea-port, near the mouth of the Ems, and 28 miles east of Groningen, is the largest town of East Friesland, tolerably well built and fortified, situated in a fertile tract of country, and containing 8000 inhabitants. The harbour is excellent, and the trade of the place considerable, especially in cheese, linens, and wines. Frederick the Great of Prussia exerted himself anxiously for the extension of its commerce; and, in 1750, established an East India company. But his forcing system did not comport with the republican spirit of the people; and many of his schemes were very ineffectual. The herring fishery, which he laboured to encourage, has succeeded well, and brings in great sums annually. Jengum, a wealthy town on the river Ems, about 11 miles south-east of Embden, is remarkable chiefly for having been the scene of several battles. Leer or Lehr, a well built manufacturing town on the Seda above its confluence with the Ems, and 15 miles south-south-east of Embden, is situated in a marshy but fruitful country, and contains 4500 inhabitants. Strickhausen, a citadel built by the city of Hamburg, about 9 miles east of Leer on the river Seda, is 24 miles south-east of Embden. Friedberg, a fortress on the frontier of Oldenburg, 26 miles east of Embden, is situated in a healthy and marshy soil, and is now in a ruined state. Essens, on the sea-coast, 21 miles north-east of Embden, is a tolerably well built town, with an old citadel. Wittemburg, a small borough and citadel in the north-east corner of the principality, between Essens and Friedberg. There are many small islands along the north coast, viz. Jyest, Norderney, Baltrum, &c. The country of East Friesland is a low, flat, and generally marshy or sandy territory. The tracts along the coast, and on the banks of the rivers, have a bottom of clay or mud, and are extremely fertile, abounding in excellent pastures; but the inland parts are chiefly sandy, heathy, and marshy, in which great quantities of peat are dug for fuel. The climate is cold, the seasons late; and the inhabitants have a stunted appearance; small round figures, yellow complexions, and freckled bodies. The fowls, cattle, sheep, and horses, on the contrary, are of a large breed; and numbers of the latter animals are exported for heavy caravans and coaches, even to Russia and Italy. There are few corn fields in the country, and butter and cheese are the principal products of the farms. One third of the whole is uncultivated, and there is great abundance of game. The river Ems traverses the south-west district; and contributes essentially to the trade and prosperity of the country. The chief articles of commerce are horses, horned cattle, cheese, butter, oats, beans, rape-seed, and fine linen. The prevailing religion is Lutheran, but the Catholics, Moravians, Jews, &c. are freely tolerated. See Riesbeck’s Travels in Germany, vol. iii.; and Playfair’s Geography.

FRODSHAM, a small town of England, in the county of Chester, is agreeably situated on a rising ground near the confluence of the rivers Weaver and Mersey, and beneath the hills which form the northern extremity of Delamere Forest. The town consists of two wide and well paved streets, intersecting each other at right angles; and at the upper extremity of one of them, upon very high ground, stands the church, which is an old and handsome building. It was repaired and beautified in 1790. Near the church is a school, with an excellent house for the master, having a cupola for the purpose of erecting an observatory. Beacon Hill, which stands behind the school, commands a fine prospect of the estuary of the Dee and the remote parts of Lancashire. The hill is now cut out into walks, which lead gradually to the summit. There are butts for the practice of archery at the foot of the hill. Frodsham Bridge, over the Weaver, is about a mile to the east of the town; and at some distance from it, on the river side, are works for the refining of rock salt, which give some employment to the inhabitants. There is a small cotton manufactury in the town, and a graving dock and yard have lately been erected for building and repairing vessels. One of the springs which supplies the town with water discharges 1700 gallons in a minute, and is used as a cold bath. Great quantities of potatoes are cultivated in the parish, amounting sometimes to 100,000 bushels, of nearly one hundred weight each, annually.

The following is the population of the township and lordship together for 1811.

See Beauties of England and Wales, vol. ii. (8)
a large and handsome building: it is 150 feet long and 54 feet broad, and consists of a nave, a chancel, north and south aisles, and four chapels. A quadrangular tower, with a neat octagonal stone spire 120 feet high, stands on the south side of the entrance to the nave from the chancel. The chancel is very elegant, the area round the communion table being paved with black and white marble. The altar piece is placed in a fine oval window, and represents a female pelican with three young ones, all superbly gilt. The organ at the west end is very handsome. Besides this church, there are meeting-houses for the Baptists, Independents, Presbyterians, Quakers, and Methodists.

There are at Frome several alms-houses and other charitable institutions. Among these is a charity school, which stands near the bridge, and is a large and handsome building of freestone. There is also a free-school, founded by Edward VI. Vallis House, the ancient seat of the Leversedges, stands on the west skirts of the town, and near it is a beautiful romantic vale, called Vallis Bottom, which runs in a serpentine direction to Mells.

The principal manufactures of Frome, are broad cloths and kerseymeres, which are made to the extent of nearly 150,000 yards annually. There are several mills for fulling, and for the rolling of iron, &c. on the banks of the river; and knitted worsted stockings, and wool cards, are likewise made. There are in the neighbourhood, mines of coal, lead, manganese, and a variety of useful clays. Frome has long been celebrated for its fine strong beer; and, at the sign of the Bell, a cask is kept as a curiosity, which contains no less than 600 puncheons. The position of Frome steeple, according to trigonometrical observations, is West Long. 2° 18' 4", and North Lat. 51° 13' 47". The following is the population of the parish, in 1811.

Number of houses, 1722
Number of families, 1909
Families employed in agriculture, 222
Ditto in trade and manufactures, 1333
Males, 4179
Females, 5314
Total population, 9193
